Automobiles are compelling new methods of road-construction that provide either a solid surface like brick, wood block or a concrete bed with tar and fine stone surfacing; macadam or gravel bound by asphalt, tar or glutrin; or gravel with surface application of oil or calcium chloride to lay dust. Water-bound macadam roads are out of date and a waste of money where there is much automobile traffic. When good gravel can be secured, it is likely to make the best and most economical country and private estate road if given the same attention in construction and care as was given the old macadam roads. In nearly every section of the country, good binding gravels are to be secured, such as the white cementing churt of central Georgia, the red Paducah gravel near the junction of the Ohio and Mississippi, the gray Peekskill gravel of the Hudson River, the reddish cementing gravels of eastern Wisconsin and the foothills at Santa Barbara, California, and the gravelly clays of the sandy foothill section of North Carolina of which so many hundred miles of excellent low-cost roads have been made about Pinehurst.

For little used drives and walks, well-drained turf or a covering of pine-needles or deciduous leaves are serviceable and attractive with a low maintenance-cost. Walks can be carried down steep places attractively with a minimum disturbance of the surface and vegetation at the lowest cost by the use of stick instead of stone steps. These are made of rounded or square pieces about 2 feet long used as risers for earth or sod treads and held in place by stubs driven down in the face at each end.

Sometimes a public water system is available, or a natural gravity supply either for direct service or to operate a hydraulic ram or a water-wheel pump to force water to a reservoir. At other times windmills, gasolene, hot-air, steam or electric pumps are installed to force water from dug or driven wells, ponds or streams, to an elevated reservoir that will give gravity supply, or to air-tight tanks at lower levels from which the water is forced through the supply-pipes by air-pressure.

It is very important that sewage be disposed of in such a manner as not to contaminate the water-supply. It is very likely to do so if it flows on the surface, through the ground from the ordinary leaching cesspool; or into sink-holes as it often does in the limestone regions of the South. The danger is multiplied under such circumstances if the supply is taken from a spring or stream or well below the house-level. Even if the owner's water-supply is taken from a higher level one should consider the neighbors below in the disposal of his sewage.

There are many sewage-disposal systems now devised that will, if properly constructed and maintained, so modify the liquids as to make the outflow pure and safe. They are based on the fact that bacterial and chemical action in so-called septic tanks combined with the action of the air on thin films of liquid filtering through sand and coarse gravel over which it is discharged intermittently from syphon chambers, will destroy all dangerous organisms.

City plats and squares.

A number of men who practise as landscape architects also call themselves city-planners. Such men and others in the profession are leaders in the city-planning movement that has, within a very few years, gained such marked headway that most cities and many small towns have plans prepared for their future extension, and some states have provided for planning-boards in cities.

Such plans include a provision for public parks and parkway systems, main thoroughfares, transportation lines and terminals, and for centers about which public buildings are grouped, for playgrounds at frequent intervals throughout the city, for public squares, and such other public open spaces as the special needs of each city indicated as desirable.

The tendency is to make such plans take advantage of the irregularities of the topography and fit them more closely than do many of the early plans that require a vast amount of cut and fill to make the surface fit their lines, to provide wider and more direct main traffic thoroughfares, to omit unnecessary curves in roads and paths, and to locate public buildings and monuments at points where they will form effective street terminals without interfering with direct passage.

The accompanying sketch (Fig. 2083) of a public square and its arrangement is an indication of this tendency, for the passages across it make direct routes from street to street. The proposed structures would represent a place for effective street terminals. Provision is made for the comfort of the public in the placing of drinking-fountains and seats set back from the sidewalk line. Enough trees are provided to give shade, and a place is indicated for flower-beds where they will not interfere with the openness and breadth of the center of the square. Such squares are coming to be islands of safety and places in which to rest in the center of great thoroughfares and towering buildings. The pretty flower-gardens, curving walks and playgrounds that might be appropriate in the less crowded residential section would be quite inappropriate in a city square.

Note that these public squares should be dominated by directness and simplicity. In these crowded meeting-places there is no warrant for the fancy curves and "features" that are often made so much a part of many landscape designs. Fig. 2084, for example, shows inadmissable plans for a busy city square, with no main passages and no opportunity for somewhat secluded or recessed seats. They partake more of the character of labyrinths, and would be more in keeping in grounds where a very few persons enjoy ample leisure, or in residential parts of cities.

The general results.

There is a growing spirit of coöperation and harmony among those who are developing landscapes and gardens. A distinctively American custom is that of throwing the front lawns together on each side of a residential street in order that all who pass may enjoy the greater breadth and beauty thus gained. A constantly increasing number of persons is considering the neighbors' interests as well as their own in the location of buildings, plantations, in the cutting of trees and in other features of the planning and making of a place. There is less of that kind of architectural and gardening originality that makes a place so out of harmony with all its neighbors as to make it an offensive vulgarity even though it may be fine in design.

For a history of landscape gardening see the introductory article. For a clear knowledge of the underlying principles that govern the profession, the reader is referred to "Charles Eliot, Landscape Architect," by his father Chas. W. Eliot; "Art Out-of-Doors," by Mrs. Schuyler Van Rensselaer; "Italian Gardens," by Chas. A. Platt.

There are many available books, American and English, in which the principles of design are referred to, but in which such practical considerations as the making and the laying out of plans, methods of construction, the description of plants and methods of cultivation are the most important parts.

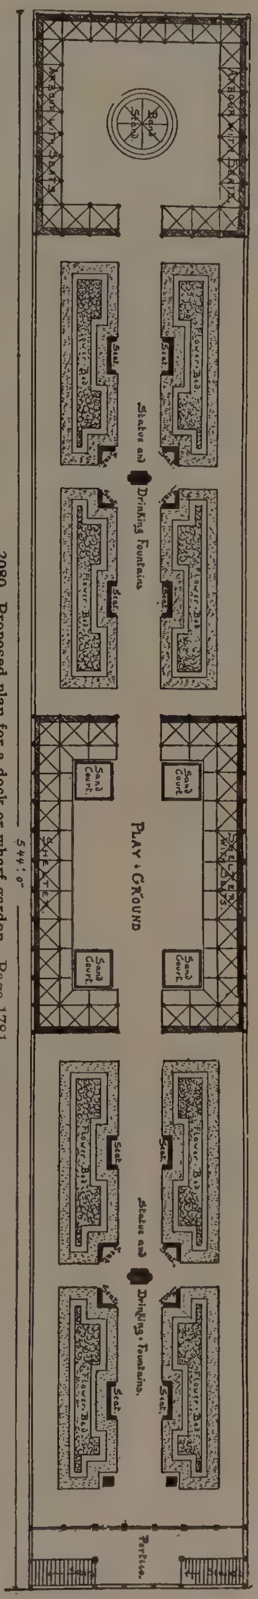
WARREN H. MANNING.

The Japanese garden.

Of a different and peculiar type, very intimate and personal, is the Japanese garden. It proceeds on different principles from the American and European garden. Examples are sometimes seen in this country, and it is well to understand the motive of them and to know what they hold in promise for us.

The garden in Japan.

It has been the theory in Japan that everyone should provide his home with all the joys and comforts associated with a garden, with the idea that it is not a general habit on the part of the housewife to secure her pleasures outside. Unlike others, the people of Japan are not contented merely with trees or flowers, but must add the rocks, streams, stone lanterns, outdoor wash-stands, wells, fences, with carp, frogs, crickets, and even bronze stalks. On the ground, one occasionally finds a private shrine, which is decorative rather than holy. A lake or pond wanders in all manner of angles, arched with projecting trees, and often dwarfed pines protect the

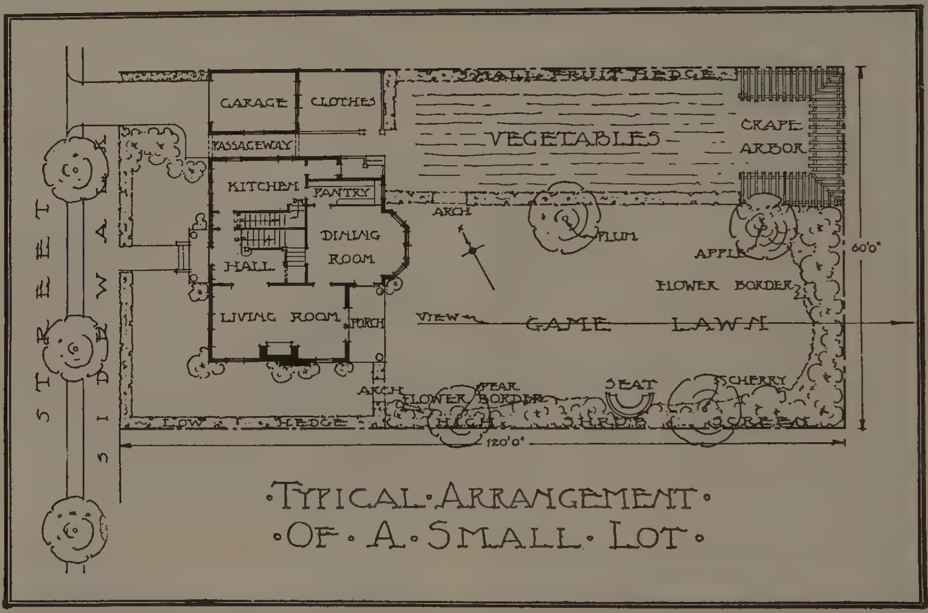


2080. Proposed plan for a dock or wharf garden. Page 1781.

goldfishes from their enemies. It floats a boat, surrounded with duckweeds or water-nuts. On its edges, there grow iris or reeds. (Fig. 2085.)

The laws of linear and of aërial perspective are carefully observed, no matter how large or small the garden may be. The relative stature of things, both near and distant, lightness and darkness, openness and density of foliage, the splendor or delicacy of their flowers, whether in size or in color, the season of blooming, the contour of the grounds,—all these points must be taken into account in determining where objects are to stand and how they shall be grouped. The character of the trees or shrubs controls the main part of the garden. Foreigners often feel the aspect to be rather gloomy, and to untaught eyes the best garden may be nothing but a patch of a grove.

In Japan, a greenhouse or nursery plot is never shown in the garden itself. The flowers have no recognized status or existence. They are usually hidden, and brought into sight only when in bloom. The roses, the lilies, the saffron, the balsams, the sunflowers, the chestnut trees, and many other things are not considered to be garden plants, whereas the bamboos, the oaks, the pines, the plums, the iris, the wistaria, the azalea, the lotus, the camellia, and others, are important. The maples are popular, but never the weeping willow. Some think it is an unlucky omen to the family that plants the crape-myrtle, grape, and other fruit trees. The different ways to place the trees or rocks indicate the degree of happiness of those who use the garden.

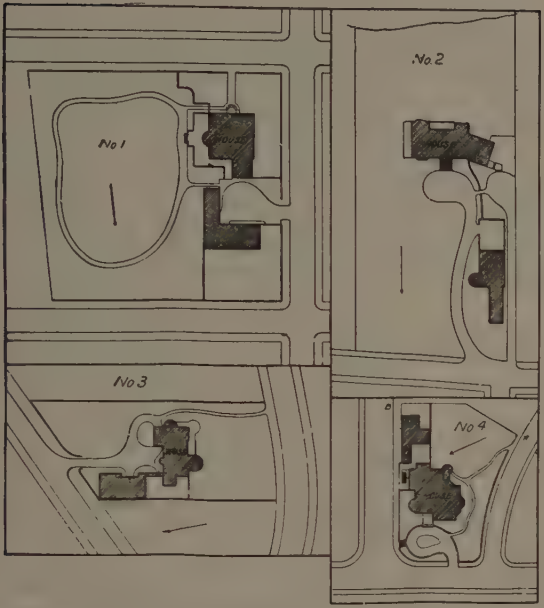


2081. Suggested arrangement of a small lot in which the desirable outdoor compartments of the grounds are properly associated with the indoor apartments of the house, and in which there is a minimum amount of road and walk surface to connect the different compartments. Each of the fruit-trees may be grafted or or budded to early, medium and late varieties. The small-fruit hedges may be made of such things as gooseberries, currants and juneberries, with the trimming to develop the fruit and to give also a uniform outline. The border planting is designed primarily to give seclusion and to screen objectionable views or to frame in attractive views; incidently, it may give an abundance of attractive flowers.

Yet the prime test is the proportion of the whole, and the arrangement of the walks in their prescribed order. The soil is bare or sometimes covered with mosses,—not lawns,—and it is cloven by a series of stepping-stones, leading to a little pavilion, sufficient to celebrate an old-school tea-party, or to a moon-viewing hillock, or to a place where one may secure a cool breeze on a summer evening or take a free sun-bath on a winter morning. It is a real revelation to have these privileges on one's territory, especially to those in the metropolis where the houses are thickly built. Some walks are so small that they are hopeless to set a foot in, although they may be a good imitation of some famous piece of scenery, with hills, valleys, cascades, streamlet, lakes, islets with trees; looking at the garden from the house, one may enjoy it as a sort of living picture. So, a little box of a foot square brings forth a landscape similar to a park of many acres.

There are so-called natural and formal gardens. The right choice between these two aspects of the art depends on the space, and on the features of its surroundings. While the spectator desires the innumerable delights of artistic work, he is loath to lose the hint of nature in a tiny dwarfed tree. The mountains farther back should be small and low, without trees, whereas those in the near distance must have much vegetation. The bed of the pond or river at a distance should be made high, and the nearer ones low. If one would show a pond larger, or cataract higher than in reality, one must exhibit only their parts, not an entire pond or river. The view should be appropriate throughout the year, and the sight acceptable on any occasion, either at the time of a little gathering or of a feast; it should be untiring to the eyes of daily admirers, and should discover something new to the frequent visitor.

One man sometimes devotes half his life to a single garden, as a garden could not have been completed with a single kind of stone unsuitable to the place. Each leaf and each twig has its direction as well as proportion, regulated by the most rigid and immemorial principles. The gardeners in Japan seem to have the knack of turning the plants into almost anything they like, thereby representing beasts, fishes, and even human figures. Even a supporting post for an old leaning tree, a straw-cover to protect the shrubs from frost, and a board or fence which is a reminder of shipwreck, enter into the place as part of its attraction. Of course, the hedges or fences are not the frame of the picture, but the important part of the garden. In one of the noted public gardens in the middle west of the main island of Japan, one would see a purple precipice of enormous



2082. Suggestions for subdivision of small grounds. Page 1786.

height yonder, with a forest of several ages, and down in its front lie the shrubs, rocks, and streams, the space between the two being made indistinguishable, as if both were in one stage.

No matter what nobility owns a garden, thousands of modest cottagers are now and then permitted to peep in, and to present their opinions, and such opportunity has gradually led them to provide lovely little gardens about their dwellings at virtually no cost or no burden. It is told that this gentle art is still largely kept a close secret of craftsmen, and has scarcely been put into books. Nevertheless, the soul of the household is conveyed into every garden, to open the flowers and to grow the trees, and not merely the skill of some hired gardener. Upon the principles laid some centuries ago, the sweet flowers enlighten the harmony of the family, the vigorous shrubs give a feeling that they have grown there in the course of the years, and so they all convey to the house a quiet air of being long married or a mother of growing children. This is the real sentiment of the Japanese, who can hardly live even a day without a garden. ISSA TANIMURA.

A classical Japanese garden (Verbeck). Fig. 2086.

The art of gardening was brought to Japan from China and Korea by the Buddhist missionaries in the sixth century. The first gardens were attached to Buddhist monasteries and generally were representations of celebrated scenes in China. Religious significance was given to their construction and the principal stones were named after Buddhist deities or their attributes.

From the Fujiwara to the Ashikaga era (seventh to thirteenth century), the evolution harmonized palace with garden, and bridges, small cottages, and conventional garden ornaments were introduced. During the thirteenth and fourteenth centuries, under the influence of the priests, Muso and Soami, of the Zen sect, the "Cha no yu" or "tea ceremony," made itself felt in the evolution of the garden which thenceforth was given a further religious character. Other great exponents of the religious "tea ceremony" were Enshiu and Sen-no-Rikiu; the latter designed the gardens at Fushimi for the great Hideyoshi in the sixteenth century. Both have left many monuments in the shape of beautiful gardens now existing. The laws of gardening established by these masters form the basis of all conventions of the art of landscape gardening in Japan today. Later artists elaborated landscape gardening until in the more recent Tokugawa era the art had reached its highest refinement.

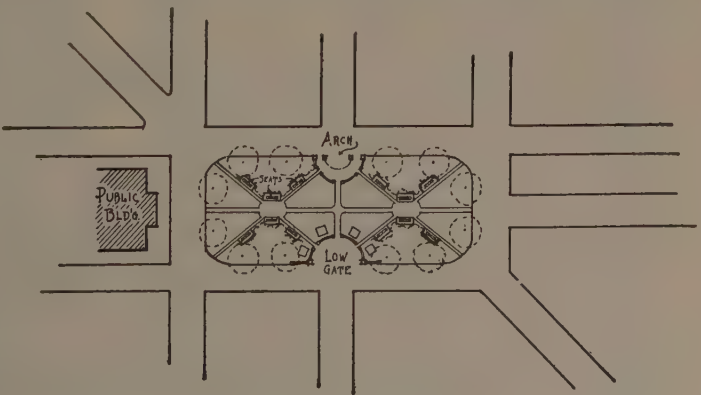
Many schools of gardening have been evolved from the classical models. There are the hill and the flat garden, those where the pond is the feature and others where the water is merely outlined and represented by dry water-courses of pebbles and sea-sand. There are the finished and highly ornate style; the intermediate or less elaborate style, following nature closely; and the free or rough style where bold and simple treatment predominates and but few of the conventional elements are introduced.

The Japanese garden is mostly green and is not of flowers. It is the scenery of a country in miniature, and gives the impression of a picture. The undulations of the hills, the outcropping of rocks and distribution of verdure closely follow nature. Hills, stones and trees have special names and have an order of rank according to shape, location, function and sacred character. Stones constitute the skeleton of the garden to which hills, vegetation and water-courses are subsidiary. Sex is attributed to stones, large, bold and rugged masses being regarded as masculine when placed in apposition to lower masses which are supposed to be feminine. Stones should be irregular and well-worn and placed as if arranged by natural forces.

In a Japanese garden there is a preponderance of evergreens for effect in winter. Of deciduous trees the plum and cherry are favored because of their breaking into leaf early in the year, and maples because of their autumnal coloring. Free use is made of azaleas, magnolias, camellias, rhododendrons, wistarias, tree peonies, daphnes, hydrangeas, and so on. Clipping and shearing of trees is much practised. Pines are bent into conventional shapes. Trees are stunted and dwarfed for use in the distance to heighten the effect of perspective. Flowering plants are placed in handsome pots adjacent to the dwelling. Iris is grouped near wells and watercourses.

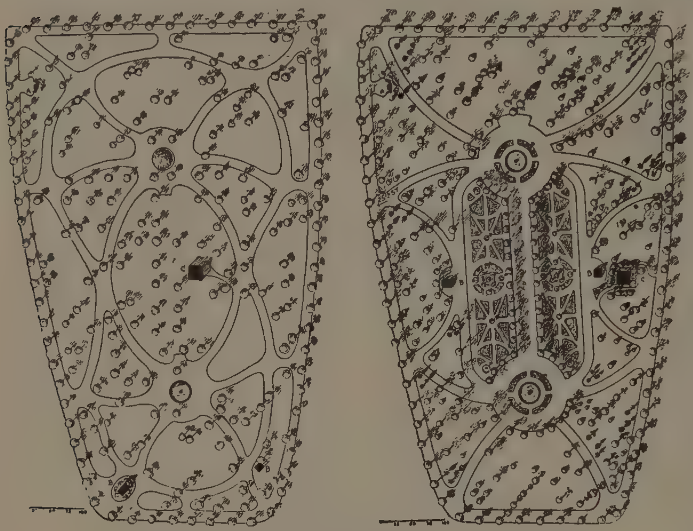
A typical garden following the classical ideals in intermediate style is here outlined.

The dwelling is so placed as to shield the garden from the malign influences of the north wind. The extreme vista must be to the south where rises hill 1, an imposing conical mound representing a distant mountain with sweeping sides. Beside it, to the left, should be its consort, hill 2, of lesser height and gentler slope. On the further slopes should appear a fringe of foliage to act at once as a frame to the picture and to harmonize it with scenery beyond the garden. Rising



2083. Plan for an open block or "square" in the busy part of a city. Page 1789.

from this group at the southern extreme should be a bold pine or oak, called Distance Tree. In the valley formed by hill 1 and 2, and shaded by a group of trees designed to produce the effect of profound solitude, flows a rivulet which terminates in a cascade. The first step of the falls which forms the cascade is high and narrow and is arrested by "Torrent Breaking Stone" which breaks it to form the second step of the cascade which is broader but of lesser height. The upper falls represents the male, and its consort, the lower cascade, the female element. Above the falls should be an image of Fudo, the presiding Buddhist deity of the waterfall, or a representation of the image by a stone in the semblance of a statue. To the left of the cascade should be the Guardian Stone, the most prominent feature in the garden. It should be a tall sentinel-shaped stone placed so as to seem to guard the garden, and represents the male element. Paired with it on the opposite side of the cascade should be the Cliff Stone, a lower stone overhanging the water, representing the female element.



2084. Inadmissible plans for a city square. Page 1789.

The Cascade Tree cunningly screens the waterfall to produce the effect of indefinite height. Minor trees and shrubs may be added to assist in this illusion or to conceal the water-supply. A short cataract then carries the waters to the lake which forms the central feature of the garden. Around this lake are winding walks and intersecting mounds and hillocks sloping to the water's edge, terminating in sandy beaches, and interrupted by great stone rocks or slabs and promontories, often ornamented with granite lanterns or pagodas. The contour of the lake is often an irregular triangle, the base of which is at the Principal View, adjacent to the dwelling. The other two sides taper toward the cascade which is at the apex of the triangle in the south, simulating the vanishing point in perspective. This effect of artificial distance thus created is further heightened by putting the largest trees and garden accessories in the immediate foreground and arranging others so as to decrease in size toward the distance.

The art of stunting trees grew primarily from the demand for dwarfed trees for use in producing artificial perspective and only secondarily from their use in the miniature garden. Trees of different species are grouped to contrast with each other, first, by form, and second, by color, and are placed in valleys or lower slopes of hills. The principal promontory should be bold and prominent and jut from one side of the lake so that a secondary view can be had of the garden only next in importance to the primary view at Perfect View Stone which is near the house. The distant peninsulas or promontories diminish in size. Portions of boundaries of the lake are so obliterated by shrubs and stones as to give the impression of indefinite extent, as if the visible waters were part of a large sea or chain of greater lakes. The base of the hills is covered with evergreen bushes clipped into spherical shapes interspersed with related rocks. The outlet of the lake should be in the west, to follow the law of the garden, that the water-course must follow the sun. Hill 3, which is a foothill of hill 1, is usually placed in the west. In the depression between the two should be a grove intended to suggest the location of a concealed hamlet. The principal feature in the west of the garden is Setting Sun Tree, generally a maple or other tree of red foliage, so placed as to cast the long shadows of the evening sun over the lake. Other trees are Perfection Tree, in the intermediate distance, of moderate height but classical contour; Tree of Solitude, to give secluded aspect to a portion of the garden; Outstretching Pine, overhanging lake, and so on. Hill 4 may be placed at the east to offset hill 3. Hill 5 is a slight elevation at the base of the garden to the north, on which Perfect View Stone is generally placed, and from which point the best view of the garden picture may be had. Near it may be placed Worshipping Stone, or it may be placed on an island. Moon Shadow Stone should be in the group of trees dedicated to solitude. Other stones are Snail Stone, the largest of the stepping stones, Idle Stone, Water Tray Stone, Stone of Two Deities, and the like.

Correctly speaking, two islands should decorate the

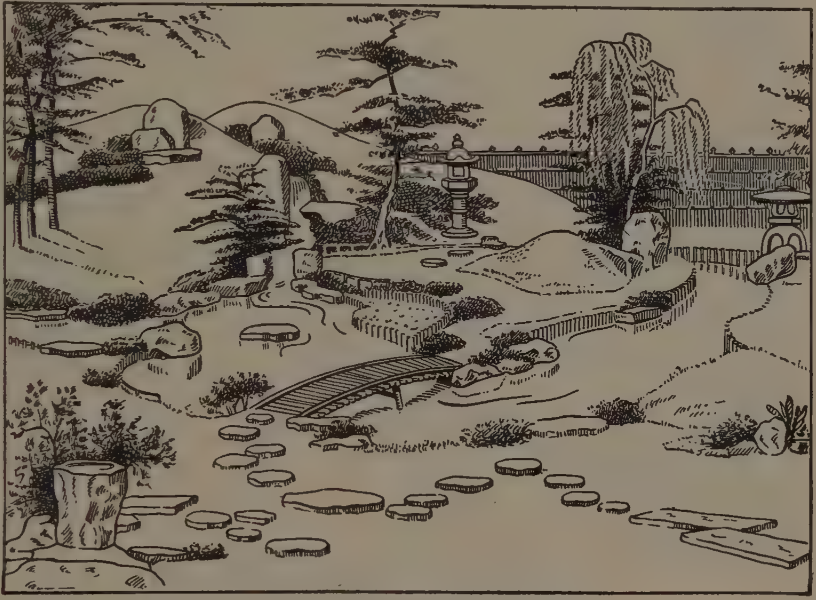
2085. Parts in Japanese garden design.

lake. The larger one is called Master Isle and is placed in the foreground. It should be easily accessible from the bank nearest the dwelling by stepping-stones, causeway or a narrow neck of land. A tea-house usually ornaments a promontory overlooking the lake. The names of stones on the island imply functions of ease and recreation, such as, Amusement Seat Stone, or Stone of Easy Rest. The second island should be smaller and is called Guest Isle, in honor of visitors. It is located in the background and the stones on it are named Guest Honoring Stone, Stone of Obeisance, Shoe Removing Stone, Water Fowl Stone, and so on.

Carefully studied effects from nature are introduced to blend the whole into a harmonious and well-proportioned picture. Variations and adaptions from such classical models are made according to taste of the artist, or to conform to the natural features and limitations of the location.

The author is indebted for assistance in preparing this article to the work "Landscape Gardening in Japan," by Josiah Conder, who is the recognized authority on the subject, from which two of the sketches in Fig. 2085, and also Fig. 2086, are adapted.

William Verbeck.



2086. Japanese garden, with stepping-stones in the foreground.

Formal gardens.

Historically considered, the formal garden is the gradual, natural evolution of the herb- and vegetable-garden which, since time immemorial, for household convenience was established near the country house. This garden assumed geometric form, because economical in space, easy of arrangement and distribution and obviously well adapted to the shape and proportions of the house. It was inclosed for safety; it had a central water-basin for watering convenience. Medicinal plants, small fruit trees, espalier fruit trees, and household vegetables were grown within the inclosure.

Very early, undoubtedly, in the artistic development of peoples, the beautiful aspects and possibilities of such gardens at different seasons of the year must have become apparent. Hence came a desire to improve the general effect by proper arrangement of the plants by well-balanced proportion, by ornamentation, and by cultivation and improvement of the original utilitarian plants, or by the introduction of new ones. Gradually, with a keener appreciation of beauty, persons began to separate the utilitarian part of the garden from the part devoted to pleasure and where only one inclosure catered to the physical and spiritual needs of the family, two separate units appeared: the pleasure- or flower-garden and the kitchen- and herb-garden. The geometrical form was naturally retained. The design remained symmetrical, well-balanced, harmonious. The inclosure, when of masonry, became an architectural feature adapted to the style of the house. If hedges were used, they were clipped and kept at uniform height. This cutting and trimming of the hedges invited attempts at producing, with the shears, green ornaments and fanciful shapes, and the topiary art was born. The central basin of water originally intended for purely utilitarian uses became the pool, the fountain. Trellises, small temples, statues, well-paved walks and ornaments of all kinds were gradually introduced and the formal garden slowly produced itself.

With the development of the fine arts and the accumulation of wealth, the art of gardening prospered, and the same principles of design which governed the arrangement of the pleasure-garden were applied to the more extensive layout of the entire country place.

Congruity, utility and convenience, simplicity, harmony and balance, the fundamental principles of all landscape design, found obvious expression in the formal conception. Thus the formal naturally became the first style of gardening.

This evolution is clearly apparent in all the great periods of history: in Asia Minor, in Greece, and in the Roman Empire. With the consolidation of the political, economic, and artistic conditions of those great civilizations, and coincident with their reaching the supreme stage of development, the art of gardening, exclusively formal, reaches its highest form of expression.

Political and military conditions in the Middle Ages shrink the villa-gardens to their original proportions of a kitchen-garden close to the walls of the castles, while the return to freedom, culture and wealth during the Renaissance restores the gardens to their former favor, nay, to a splendor never equalled before nor since. France and England imitate the Italian garden-art at first, then forge rapidly ahead to great achievements of their own.

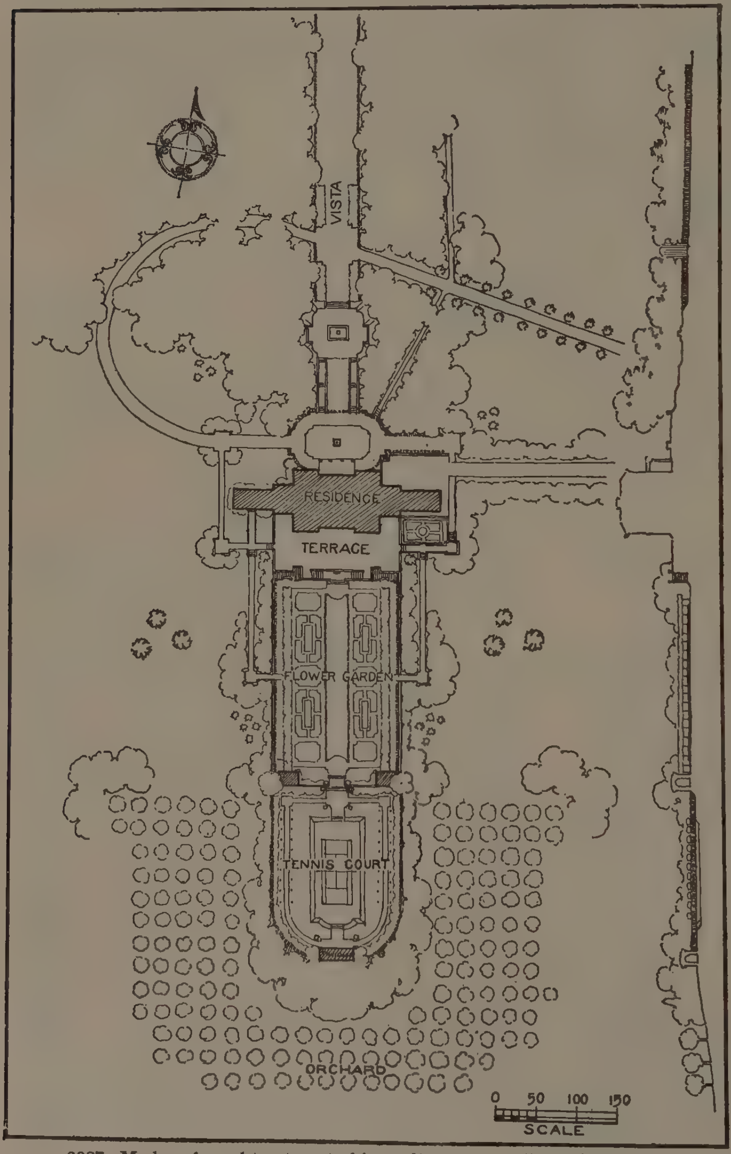
In America, one may follow the same cycle. From the herb- and vegetable-gardens answering the same purposes and disposed in the same way as those of antiquity, the art gradually develops and reproduces on a somewhat smaller scale, and in a more intimate and simple fashion, the formal gardens of the mother countries. The colonial gardens appear in New England and in the southern states, and gradually spread all over the settlements of the Atlantic coast. Historically, therefore, as well as technically, the colonial gardens belong in the general class of formal gardens.

Technically analyzed, formal gardening, in its best forms and examples, covers a limited area in the immediate surroundings of the country house and is intimately connected with it and its outbuildings. The principal axes of the house are prolonged and maintained as the principal axes of the gardens. Some of the adaptations are shown in Figs. 2087–2091.

In size and shape the gardens maintain a definite proportion and are well adapted to the size and shape of the buildings, even more than to the general conformation of the ground. The designer depends upon his ability to mould surfaces not to do violence to the general aspects of the country and carry out his work in harmony with the architectural structures. The extreme difficulty of doing this marks more than anything else the few really successful works of the kind. The disregard of such harmonious combination, and the consequent exaggeration of the artificiality of the composition is the surest sign of the decadence of the art.

The house is usually set on an eminence commanding a good view of the country as well as the gardens. Around the house, an esplanade, or first terrace, is, more or less laboriously, architecturally treated, and is connected by stairways with a lower terrace or parterre designed as a flower-garden. In this way, a connecting link between house and garden is secured, and the part of the grounds nearest the residence is arranged so that the eye can embrace at a glance the whole of the design and enjoy its beauty and the fascination of its color. Very often a third still lower terrace is less elaborately treated as if the intention of the designer were gradually to prepare the visitor for the end of the formal and the beginning of the picturesque surroundings of nature.

The ground plan being geometrical and symmetrical, the arrangement of vegetation is necessarily geometrical and symmetrical. Stately avenues constitute the approaches. The terraces are rectangular: special motives rectangular, circular, or elliptical. The flower-beds generally conform with the arrangement of the footpaths; often, as in the "parterres," they are designed in patterns of elaborate nature made with dwarf edging plants and filled with great varieties of flowering herbaceous plants. All vegetation is either of such nature that size and character remain uniform throughout the year, or it is made so by the use of the shears, or by periodical transplanting.



2087. Modern formal treatment of immediate surroundings of house on a large estate in America.

Water is usually made to play an important part in the composition. Pools, fountains, and cascades are ordinarily used as main features of design; often as secondary motives. Large surfaces of water add by their reflections to the charm of the general composition. Fountains and cascades contribute their lofty jets, and the pleasing sound of moving water to the animation of the garden.

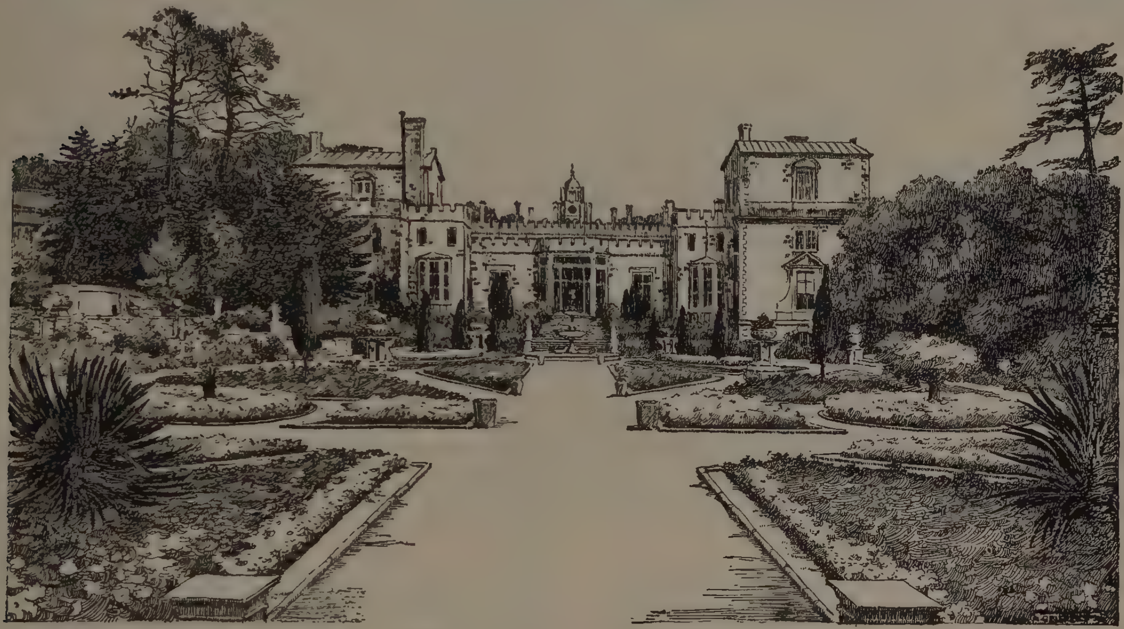
Seclusion is essential in all formal composition. By inclosing a garden within walls, hedges, or heavy planting, a frame or setting is created which gives relief to the design, clearly defines the area of the picture and compels the eye to abstract the inclosed part from the remainder of the environment. Finally seclusion gives privacy, making the formal garden what primarily and essentially it should be: a drawing-room in the open air.

If we now consider the art of formal gardening from the botanical point of view, we are compelled for the first time to make geographic and climatic distinctions.

Although the formal gardens of Italy, of France, of England, and of America are substantially the same so far as principles of design are concerned, they vary considerably in the nature of the plants used. Possibly, it is due to this fact that in the popular mind a technical distinction is made between Italian and French or English formal gardens, while in reality there is none. So one speaks of Italian or French, or English style of gardening, while the style is independent of the country where it is used. There are formal and informal gardens in all countries and these only should properly be called styles.

A botanical analysis of the formal gardens is here out of place. Moreover, it would require considerable time and space. We may, however, sketch summarily the character of the botanical materials used, keeping in mind that species and varieties necessarily vary according to locality and climate and are modified by soil conditions.

Avenues are usually made with deciduous trees of symmetrical and enduring form, such as oak, linden, locust, plane, and the like. Often evergreens are used: cypress, holm oak, pine, cedar. Hedges are usually evergreen and made of material that will easily stand the shears: box, arbor-vitæ, holm oak, hemlock, holly, yew and so on. The design of the parterres is outlined by means of dwarf box edging inclosing geometrical spaces filled with low-growing annuals or perennials. Roses are also very commonly used for this purpose.



2088. An open-center formal treatment.

Perennial and annual borders are planted against walls and hedges either in masses of single varieties or mixed in order to secure so far as possible a definite arrangement of height and color and to procure a succession of bloom.

Specimen evergreens of geometrical shape, such as conical, cylindrical, globular and spiral, are used to accentuate points of interest in the design or to establish the corners of beds in parterres, or the corners of hedges, or the axis, and so on. When the topiary art is given more freedom, the ornamental evergreens assume the shape of birds, ships, tables, and the like. Box, yew, and privet seem to be the most favorite materials for this work. Sometimes the same effects are obtained by growing ivy over a wire frame representing the object desired.

Plants in tubs or in ornamental vases, such as bay trees, lemon, or orange trees, box, century plants and oleanders, are intended, as a general rule, to supply ornamentation during the favorable season with plants which require the shelter of the greenhouse or the orangerie during the winter.

It has already been seen how in America the formal garden gradually developed by the same process that brought it into existence elsewhere. The colonial garden clearly reflected the social and economic conditions of the times in which it was produced. It was simple, well-proportioned and exceedingly well adapted to local conditions. It was small, secluded by a hedge or wall or fence covered with vines. The flower-beds were well defined by box edging; the paths were paved with brick. A good use of a few shrubs was made in these gardens, such as lilacs, mock orange, forsythia, calycanthus, and the like, to fill the corners, to soften the architectural lines of the house or the terrace, to give privacy to the entrance or to the porch. The lady of the house took charge of the garden and special care of the perennial and the annual beds. Most of the flowers acquired sweet, attractive names, reflecting an age of delightful sentiment and real love for the out-of-doors. To give only one example, the *Viola tricolor* or English pansy was known as ladies' delight, bird's-eye, garden-gate, none-so-pretty, Kitty-come, Kit-run-about, three-faces-under-a-hood, come-and-cuddle-me, pink-of-my-Joan, kiss-me, tickle-my-fancy, kiss-me-ere-I-rise, jump-up-and-kiss-me, and finally meet-her-in-the-entry-kiss-her-in-the-buttery, which is the longest plant name in the English language.

Since the colonial days, very much has been accomplished in the United States toward the development of the art of landscape design. The great variety of topographical conditions, of climate and soils, offered to the artist diversified problems and opportunities. The formal style has been used in moderation on the whole, and, if one disregards a few sad mistakes, with a great deal of common sense. The prevailing opinion is that its best adaptation is in the very small properties where it is evident that the house and the boundaries are too geometrical and close to allow aught else than a formal design. In the medium-sized country place when the topography is flat and several properties are close together, it is sometimes advisable, but, as a general rule, and certainly in the case of large estates, the formal style finds its best justification in the immediate surroundings of the buildings because their artificiality cannot be hidden or transformed. Here it usually answers all purposes of convenience and utility as well as it reveals harmony of composition. It is in fact the best means of gradual transition from the architectural to the rural and the picturesque.

The landscape treatment of small grounds.

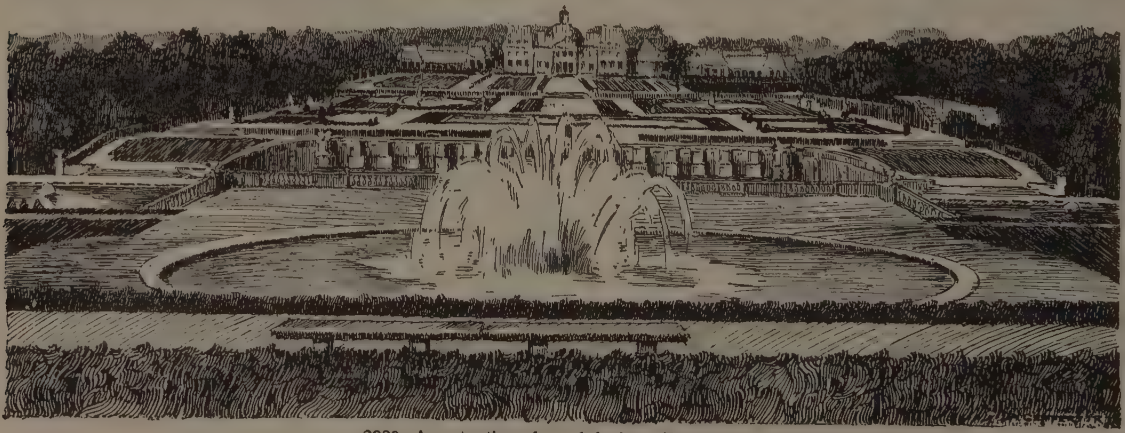
The art of landscape gardening is to many persons a subject that belongs only to landed estates or to great public parks. By them it is not expected to serve with its principles or its practice their modest suburban or city-lot-size home grounds, although in the same way, if upon a smaller scale, they seek tasteful, practical, interesting arrangement and embellishment. The home grounds is a problem not unworthy the finest art or the most expert landscape designer. Small places everywhere are becoming more and more charming as architects meet a growing demand for better houses, and their settings become more and more appropriate and pleasing, as owners, gardeners, and nurserymen apply the achievements of landscape gardening which they have observed. Many small places evince a beauty and effectiveness surpassed by larger ones only in extent; but for the most part they fall short of their possibilities and attain to a degree of artistic value limited to the mere beauty of the plants set out. That one place can surpass another of equal building-lot proportions and comparative amount of planting would lead to the conclusion that, for the designing of small grounds, there may be underlying principles practised in some cases, neglected in others. Achievements of good design are evident; methods, seldom.

Spaciousness does not make, but may enhance, beauty in grounds; but mere space suffices to lend independence, more or less seclusion and privacy, character and dignity. Hence the small place, more than the large one, must depend for its individual effectiveness and setting upon the general beauty of its neighborhood,—its environment; upon well-placed community plantings, and upon the skilful management of a principle of design called unity,—the tying together or harmonizing of all features of the scene in view at one time. Realizing this, it should ever be the paramount aim of a community or platters of real-estate subdivisions to retain all of the natural features and landscape character possible by preserving old trees, ledges, rivulets, good views and good building-sites unmolested, and also, so far as possible, to obliterate neighborhood eyesores. When land is laid out and houses constructed or at least restricted, by the same company, the greatest opportunity is afforded to realize the utmost of landscape and community attractiveness. To artistic grouping of buildings, to directing courses and appearance of streets, to preservation and adaptation of natural scenery for common enjoyment, should landscape gardening, as well as engineering and architecture, lend its best effort. Such development reflects directly upon very limited lot areas and affords a charm of environment impossible of attainment otherwise,—except by merest chance. Fortunate the dweller in the modern garden suburb!

Within the lot, in order to utilize to landscape advantage every inch of space, ground study should begin with house-planning and should be determined in much the same way. This saves later regret and expense and many times improves house designs as well as preserves beauty in setting. In large estates the landscape study usually precedes; in small lots, it is oftenest the last matter thought of and generally left largely to the local grader to work out. All of our houses, as a result, become ranged in line, drilled face to the front street, commonly designed, equally spaced, uniformly graded flat, totally ignoring the hints offered in native trees or uneven ground for individual character, or of homelike seclusion possible in the back yard.

In placing houses on uneven ground, great opportunity is presented to gain distinctive character and interest or even practical advantages not offered by the more popular level site. Close to the house differences in grades may properly be shown by terracing, but it is not well that in every instance the natural beauty of uneven site be sacrificed by cutting and filling in order to create plane surfaces. In the grounds apart from the house, especially, does uneven land prove a fertile source of suggestion for landscape treatment. A low spot may become readily enough a pool; banks, rock or alpine gardens; elevations, place for planting and seat; open hollows, flower- or vegetable-gardens. How such hints may be adapted and worked together into a harmonious and livable scheme, is a landscape-gardening plan. Plans made from these hints to fit the ground are not usually so attractive on paper as those made quite regardless of site suggestions. For pure individual charm in home grounds, one likes a natural site and orderly design combined. To accomplish this is a problem.

Solutions of such problems are illustrated by the home-grounds plans here presented. Standing trees, uneven land, a large house, a lot of 125 feet frontage were the conditions met in the design of Fig. 2092. In order to preserve a large oak to spread its high head above the house roof, a retaining wall was required to hold back the



2089. A pretentious formal design. Page 1793.

bank and roots and lawn. The house terrace and side porch nestles in beyond this, and the effect is of the terrace and porch being sunk into the ground behind the oak trunk. Add the treatment accorded the remainder of the lawn, and it becomes a very charming spot. The place is attractive because all the trees were retained at sacrifice of level lawns, planting chosen which associated itself with tree trunks and shade, and the walks are curving and inconspicuous. One of them passes behind a group of shrubs to the half-hidden garage, while a branch finds a seat built into the bank like a retaining wall under rhododendrons, and looks out upon a bit of open circular grass-plot in the sun, bordered with perennials backed by a hedge. The sun-dial rests atop a huge native boulder. Simplicity is the keynote of the plan; rhododendron and naturalized bulbs, that of the embellishment.

In Fig. 2093, all open lot, a formal garden in close relation to the house is adapted to a low portion of the lot instead of filling it up expensively. The garden is one for flowers, not architecture, and the children's play-yard under the trees is a pleasant association, in keeping.

Both of these plans, and Fig. 2094 as well, illustrate a point to be observed in planning small grounds, that house-orientation may be determined as much by the factors of site as by the usual one merely of sun. If attractive views are to be had toward the rear of the lot, advantage if possible should be taken of the fact. Such pleasant possibilities for porches and windows should not be given over undisputed to kitchen service while the family seeks the little comfort possible on the "front porch." If objectionable objects are presented to the view, they should by all means be screened off. This is accomplished usually by a thick planting of ornamental trees, shrubs and evergreens. This itself may prove so attractive as again to command a consideration of the back lot, for such screens have been known to develop into beautiful backgrounds for flower-gardening, always on view from the best windows or porch and enjoyed in perfect seclusion and privacy. A logical extension of the screen-plantings is the arranging of small trees and shrubs along the entire lot boundaries for the purpose of affording seclusion from all abutting properties, or even from the street-front. This need not be regarded as a "spite-fence" or any manner of unneighborly act; for with charming material in flower and fruit, in a beautiful form, it also lends privacy to the neighbor from his side of the foliage. Landscape gardeners would say in truth that the attainment of seclusion in home grounds is an important principle of the design. Planting is a better way than fencing.

In addition to seclusion, the second most important principle of design is served by this same screen and border shrubbery—that of adding to the space an apparent extent. The eye measures straight lines subconsciously. Seclusion alone may be attained by tall sheared hedges, rows of trees, masonry walls or vine-clad fences, but, however well executed, the effect is disappointing. A feeling of amplitude, of interest, satisfying beauty, is to be attained only through indefiniteness of boundary lines and concealment of corners; by irregularly shaped open lawn; by softness and blending of color in the foliage mass that frames it. Subtle variations in grades of the lawn uniting with studied outlines of the bounding shrubbery so that one augments the other, afford pleasing variety and entrancing shadows; bits of lawn half concealed in the border by jutting foliage, paths or stepping-stones leading behind and through the border itself to find a hidden seat, a bit of a garden or unusual plants and naturalized flowers,—all of these devices tend to create an impression of spaciousness and to afford pleasant curiosity and constant interest. Such effects can be secured in areas 100 feet square. Green in foliage, especially grayish green, lends distance; yellow and strong colors shorten it. Lawns interspersed with many individual specimens, plants and flower-beds however fine, are reduced in appearance of size. A few stragglers in group arrangement standing in the lawn near the shrubbery or in studied relations to views or little vistas are allowable. (Fig. 2093.) Planting or bedding in straight rows, whether of trees, shrubs or flowers, is likely to reduce the apparent extent. But there is reason to like straight walks when they go directly to an interesting point and do not mar the beauty of a lawn-picture which they take their traveler to examine. (Fig. 2095.)

2090. The rear or personal garden in the formal treatment. Page 1793.

Secluded spaciousness in small grounds should be sought, for obvious reasons. The irregular open space bounded by soft indefinite foliage massed in a curving outline of bed seems the successful means of attaining it. The materials of which this massed border is composed is a subject determined by its relation to the general plan. As the growth should be highest and thickest where views must be intercepted and lower and thinner where they may be desired, hints are afforded as to placing jutting points and receding bays in its outline. In a general way, such borders should not comprise a catalogue of nursery stock. Choose material first which by ultimate height of growth and foliage habit serves the purpose, and secondly associate with it other material valuable for bloom, fruit or foliage. Mass these in little groups or plantations of three to ten or more, the groups uniting and running together to form a happy mixture of foliage. (Fig. 2095.) In the mixtures, however, strive to find a keynote to maintain through the whole composition. This is struck by the site, the house, the personality of the owner. It may be a wooded place and woodsy plants like cercis, cornus. single viburnum, amelanchier, or hemlock and white pine and arbor-vitæ, rhododendron and kalmia, ferns and little naturalized shade-loving plants, would be appropriate. (Fig. 2092.) Or it may be an open sunny place and the feeling of the fence-line or roadside wildness desired; then choose rhus, wild roses, sambucus, crategus; or birch, wild cherry, sassafras, nut trees; red cedar, Scotch pine; wild asters, sunny asclepias and coreopsis. (Fig. 2094.) If more refined garden feeling is desired, then lilacs, syringa, weigelas and deutzias, spireas, snowballs, may be used with ginkgo, magnolia, Lombardy poplars, oaks and maples; hollyhocks, larkspurs, iris and peonies. (Fig. 2093.) With rustic rockwork and stony ground one should associate plant forms of the same prostrate type,—charming low matted junipers and yew; trailing wichuraiana roses and shrubby celastrus; erect cedars, cembra and mughus pines; larch, red birch, ash and hickory; and a whole list of low alpine herbaceous flowers.

2091. The formal flower-garden or herb-garden of colonial days. Page 1793.

Uneven sites seem to demand the cultured wildness of rhododendron foliage and flowering dogwood, an absence of close-cropped effect and a prevailing freedom and informality. This may be conditioned, however, upon the demands of the building, for there are cases in which uneven ground may be better altered; that is, when the desire is to derive the gardening lines from the building lines. Uneven ground should then become terraced and embellished with plants that are more stiff and conventional in type, more man-made to harmonize with the building. Privet and boxwood hedges, and strong colors of foliage and flowers, Irish juniper, globe-shaped arbor-vitæ, *Catalpa Bungei*, sciadopitys, and other plants of strong character would be appropriate.

Besides site and association, much depends upon the personality of the designer and preferences of the owner as to choice of plants. To the methodical mind, the leaning is to rare species, individual plants, botanical sequence in arrangement; to the flower enthusiast, all niceties of color harmonies and combinations in mass; to the tree-lover, generally too little room for his hobby. To the iris, rose, peony, phlox and fern enthusiasts, room and good position is given by the front edges of the shrubbery border or at sides of paths in vegetable-garden to further his ambition; and to the bird-lover, chance for pleasure in providing shrubs which bear berries for winter attraction and comfort to his friends. But whatever is planted should be chosen with the thought of having it both happily placed in the general scheme of embellishment and thrifty in growth. Position of plantations first, choice of material second, preparation of ground and care always,—this is a home-grounds program.

Gardening and architecture necessarily meet upon very close terms in suburban-lot areas. Domestic architecture needs the softening influence of foliage, the heightening effect of trees and backgrounds, land grading of an interesting and artistic as well as simply practical kind. Hints at house design should be drawn even from the natural environment and exigencies of site. Gardening requires, in small areas especially, close sympathy with the architectural style and a subservience in its design to the practical requirements of the house and owner. Its materials, structural or planting, should be appropriate to the character of the house and to the effects that logically accompany its design. Both architecture and landscape gardening in small lots should be simple and upon a scale determined by the area at disposal, not so far as design is concerned, but dependent upon the pocketbook of the owner. Richness of material is the only proper way of extravagance, not by quantity or by mere showiness. As to planting, it is to be observed that very few places are over-planted when shrubbery is the material. Trees and evergreens more often defeat their purpose by being planted too closely.

Simplicity, then, is the third and always constant principle underlying landscape gardening in small grounds. By it is meant not elimination of interesting subjects in grades, constructions or plants, or even garden accessories, such as pools, arbors, and treillage, but fitting and unobtrusive use of them. The flowing outlines of wild copse, of modulated contour in meadow land, of unmolested trees, are simplicity ideals. In domestic gardening, such ideals should almost without exception prevail. Even if drawn down to straightened lines of formal treatment, necessary sometimes when the type of building demands architecturally treated foliage nearby, the ideal of simplicity in both design and plant material should govern the designer. Formal garden designs are oftentimes very satisfying when properly used in small areas farther from the house, reached and pivoted upon an extended house line, as straight walks from the house or terrace. (Fig. 2093.) Full of interest as regards design, beauty in detail of material, construction and accessories, and with a certain charm in its very primness set amidst ample soft flowing lines of shrubbery and trees, the small formal back yard adds a logical and an interesting feature. Sparsity of planting—not the ideal of foliage and growing things in a garden,—too much furniture, paths too wide and numerous, a lack of simplicity of both architectural and plant-forms, are reasons why formal grounds are not generally more pleasing. They are not produced successfully by mere drawing of lines, with T-square and triangle, and the amateur is safer in informal gardening. However, formality exists in each place here illustrated by house terrace and prim planting or softened wall treatments, walks, steps and walls, and even in the little geometrically arranged gardens, but dependent almost altogether upon hardy plant growth and simplicity of plan for their charm.

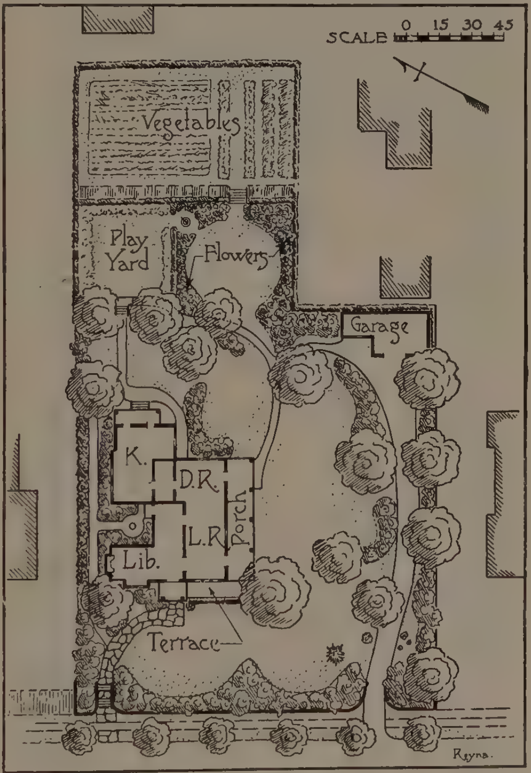
These gardens (Figs. 2092–2095) may be considered as informal formal gardens. The true formal architectural garden would embrace much embellishment of clipped trees, color balances and complicated design with much less emphasis upon foliage and floral effect. This in small-scale yards is generally bad practice, resulting in many failures, because it fails to lend the charm so urgently demanded in almost all problems. In the plans here shown, there is formal treatment so far as balance and instrumental lines are concerned, but the warming influence of natural growth saves the garden and makes it useful.

Too little thought is given by house-planners to adequate planting at base of buildings, the vital spot oftentimes of uniting house and site. The want of relief afforded by grouping of shrubbery and dwarf evergreens at this ground-line is responsible largely for that gaunt, cold, inhospitable expression many houses present. Boundaries should be planted; so also should an area immediately about the house wall. Walks and driveways should be kept at least 6 feet from the building; terraces should be arranged with planting space against the wall or outside against the terrace. The corners of buildings need especially to be supported and softened. Plants of rich and striking character are appropriate close to the house, even to sheared and tubbed plants, used to support or embellish architectural features, and close-cropped hedges of the nature of boxwood used like softened building-lines. Annual plants bedded out, or herbaceous perennials, serve the purpose in summer, but fail from their transient character. Dwarf evergreens seem felicitous by being conspicuously present in the barren season. Vines upon the wall or trellis, of course, are invaluable to relieve the blankness and do so in the least of soil-space. The softest possible wall treatment is a combination of evergreen and deciduous plants with an allowable interspersment in summer of flowering material set in front of climbing vines.

Concerning the details of developing a plan upon these premises, different designers will vary in practice. For the amateur for whom this is written, it is safe to advise at first a survey—or chain measurement of the ground locating accurately each tree, rock or native element that may stand, as well as buildings, in or adjoining the property, and views which for any reason may seem undesirable or in any way less desirable than others. These will be starting-points for a boundary planting, for the location of a garage oftentimes or even a garden to contribute to the effective screening of the view. Draw accurately on a scale of say ⅛ inch to the foot a plan locating these existing conditions and with the house plan reduced to the same scale proceed to study locations for it with consideration of all that has been said above, and with "sketchy" plans similar to those shown here search for schemes that will accomplish the needs of the place and bring out its beauty. Drawing out in this way different schemes that may be possible, coupled with observation in parks and private estates, will help most in the outlining of tasteful borders and practical unobtrusive walks and driveways. These with the lawn are fundamental in home pictures; gardens, pools, arbors, rockeries, are valuable in affording greater interest and additional service of the ground.

Much of the design depends upon the way the land may be graded and, unfortunately, there are few rules to lay down. It is quite simple to level and terrace ground to a conventional formality; to grade natural-shaped slopes is far more difficult to plan and to specify on paper and depends largely upon the ability and artistic sense of the foreman and overseer of the actual earth-moving. A visualization of the regraded surface is sometimes possible by stringing white cord from point to point adjusted by taughtness or sag to fit the desired levels. Drive grade-stakes into the ground to correspond to the cord and adjust the work accordingly. The sagging cord will give the natural undercurving line so essential to simple scenery. In either formal or informal setting, the grade across the front of a building should be quite level unless it be possible to overcome the unevenness by planting heavily the lower end. It is not necessary that the front and rear corners upon the same end be graded level, but even here the appearance of unevenness is relieved by foundation planting. Steep banks should be rounded over at top and at bottom unless amounting to a frank formal terrace, in which case the top should be a sharp horizontal line. It is obvious that in any grading, the owner of a small area should save his top soil to put back on top. Grade with the subsoil to within 6 inches at the least of the desired finished surface and use only good soil in this upper layer, being careful in the operation to get no stone nearer than a foot of the surface. A caution may be sounded also with respect to grading close to standing trees, for it is important generally that roots be not injured by cutting or exposure nor trees smothered by filling against the trunks. Standing trees restrict lowering of grades but filling can be safely accomplished by "welling in" the trunks by a dry stone wall the depth of the fill.

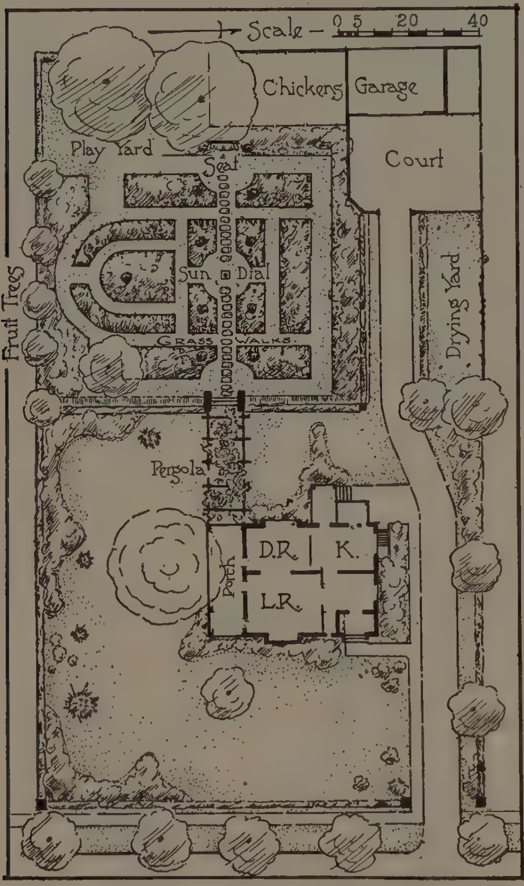
Grade and general plan being decided upon, details of planting and constructions logically follow. When the details precede, as often is the case with amateurs, unity in the place is usually lacking as a result. Fig. 2095 shows a plan developed from a sketch as suggested above, ready for the workman to carry out, for the nurseryman to supply the plants. Note the house while presenting a welcoming front door to the street, is arranged with porch and house-terrace at the rear where possibilities existed. The lawn is arranged to



2092. Uneven ground with old trees demands informal treatment.

become a clear bit of greensward inclosed by marginal shrubbery. In Fig. 2094, an open front lawn and secluded rear landscape garden determined the plantings. Boundaries are forgotten by the studied outlines of this shrub plantation, which, it should be noted, are in long simple sweeps, rather than little wiggly kinks so often seen. Projecting points and receding bays in this shrub mass afford interest to the lawn vistas, as well as seclusion to the back yard and pleasant course for the walks to the sun-dial, pool, and rustic arbor at entrance to the vegetable-garden at the extreme rear of the lot.

In Figs. 2092 and 2093, use is made of the side lawns for the family enjoyment. The boundary plantation is evident and in one case has been extended to a complete border across the street front. This was made possible by the elevation of the lawn above the sidewalk and the use of a stone retaining wall which the planting relieves gracefully. This street front might have been treated more cheaply and very well by a planted bank which also affords a pleasing street appearance and a perfectly secluded lawn.



2093. Formal garden pivoted on an extended house line.

The make-up of these plantations is of simple material chosen for good foliage, hardiness, and seasonal attractiveness of flower, habit, and winter fruit or bright bark. The plants are mainly those which mix well, without clashing of bright foliage colors or incongruous forms. The consideration of size to which the plants will attain is very important and much material valuable in the large park must be eliminated from the lists for small places. Those plants which grow slowly and are in the nature of dwarf species are appropriate and particularly useful for the permanent plantings. Quick- and rank-growing plants may be used for screens, but provision should be made here also for permanent but slower plants to come on and replace the others. Planting quick-growing material or close planting for immediate effect is a dangerous practice, for the proper thinning is usually not accomplished and the entire planting will be robbed of beauty. It is better to space plants at reasonable distances, and use less, but of large nursery sizes.

It may be valuable to note, as to choice of plants for small areas, those which were common to the planting plans of the three places here illustrated. The list does not contain all the plants possible to use in like circumstances in the northeastern states, but will afford at least an indication of choice depending upon the restrictions of space, amateurish care, results not too far remote.

PLANTS SUITABLE FOR SMALL GROUNDS.

Those marked with an asterisk (*) are common to the three places here illustrated.

Deciduous trees.

*Maples—Acer campestre, A. saccharinum and var. Wieri, A. tataricum, A. ginnala, A. rubrum, A. palmatum, in variety.
*Shad-bush—Amelanchier canadensis and others.
*Ohio buckeye—Æsculus (Pavia) glabra.
*Birch—Betula alba and B. laciniata of trade lists, B. lenta.
Catalpa—Catalpa bignonioides.
Hackberry—Celtis.
*Flowering dogwood—Cornus florida, and var. rubra. Also shrub species.
Double-flowered cherry—Prunus avium fl.-pl.
*Red-bud—Cercis canadensis.
Cercidiphyllum japonicum.
Yellow-wood—Cladrastis tinctoria.
*Beech—Fagus sylvatica, and varieties, all of which require much space for growth finally.
*Maidenhair tree—Ginkgo biloba.
Varnish tree—Kœlreuteria.
*Larch—Larix leptolepis.
Liquidambar.
*Magnolias—the Chinese species in variety. M. stellata is very low.
*Crab-apples—Pyrus floribunda, Eva Rathke, Kaido, etc.
*Ironwood—Ostrya virginica, slow and good.
*Sorrel tree—Oxydendron arboreum.
*Poplars—Populus nigra var. fastigiata, P. alba var. Bolleana.
*Oaks—Quercus palustris, Q. coccinea, Q. pedunculata var. fastigiata.
Pagoda tree—Sophora japonica.
*Mountain-ash—Sorbus americana, S. Aucuparia.
*Deciduous cypress—Taxodium distichum, very useful.

Evergreen trees.

*Fir—Abies concolor.
*Spruce—*Picea Engelmannii, P. excelsa (for screen only), *P. orientalis, *P. pungens, and P. pungens var. glauca.
*Pines—Pinus Strobus, P. Laricio var. austriaca, *P. Cembra and *P. Mughus, which are indispensable.
*Douglas spruce—Pseudotsuga Douglasii, a fine screen or specimen.
*Umbrella pine—Sciadopitys verticillata, dwarf and interesting.
Hemlock—Tsuga canadensis, nothing better under shade.

The following are really mostly trees, but used as dwarfs either for massing or standing alone. They are material which is valuable:

*Japanese cypress—Chamæcyparis, in variety.
*Arbor-vitæ—Thuya, in variety, according to form desired.
*Cedar—Juniperus, tall and dwarf or prostrate forms.
*Yews—Taxus cuspidata, T. canadensis.

Evergreen shrubs.

Andromeda floribunda.
*Azalea (Rhododendron) amœna.
Cotoneaster.
*Ilex crenata.
Kalmia latifolia.
Leucothoë.
*Mahonia Aquifolium.
Rhododendron maximum, *R. catawbiense, hybrids.
*Yucca.

Hedges, evergreen.

*Buxus sempervirens.
Thuja occidentalis, T. orientalis var. pyramidalis.
Tsuga.

Hedges, deciduous.

*Berberis Thunbergii.
*Ligustrum ovalifolium, L. Regelianum.
Rosa rugosa.
Spiræa Thunbergii and S. Van Houttei.
Rhamnus cathartica.
Acanthopanax (Aralia) pentaphyllus.
Hibiscus (Althæa) syriacus.

Shrubbery borders.

*Abelia chinensis.
Acanthopanax (Aralia) pentaphyllus.
*Æsculus parviflora, excellent in shade.
*Althæa (Hibiscus syriacus).
*Amygdalus (Prunus).
*Azaleas.
*Berberis Thunbergii, *B. vulgaris.
*Callicarpa purpurea.
Calycanthus floridus.
Ceanothus americana.
*Cephalanthus occidentalis.
*Cercis japonica.
Chænomeles japonica.
*Clethra alnifolia.
*Cornus alternifolia, *C. alba, C. mas.
*Deutzia scabra var. crenata. *D. gracilis, *D. Lemoinei.
*Diervilla (Weigelas).
*Elæagnus multiflora.
Evonymus alata, *E. atropurpurea.
Exochorda.
*Forsythia Fortunei, F. viridissima.
Grasses like *Festuca glauca, *Miscanthus.
*Hydrangea arborescens var. sterilis, H. paniculata var. grandiflora, H. quercifolia.
*Hypericum aureum, *H. Moserianum, H. calycinum.
Kerria japonica fl.-pl.
*Lespedeza Sieboldii.
Ligustrum Ibota, and var. *Regelianum.
*Lonicera bella.
*Lycium chinense.
*Myrica cerifera.
*Philadelphus, in variety.
*Rhodotypos kerrioides.
*Rhus canadensis.
Robinia hispida.
Rubus odoratus.
*Sambucus racemosa.
Sorbus (or Aronia) arbutifolia.
*Spiræa, in variety.
*Stephanandra flexuosa.
*Symphoricarpos racemosus, S. vulgaris.
*Syringa—the lilacs in species as specimens, and in hybrids.
Viburnum Opulus, V. Lentago, *V. tomentosum, and var. plicatum.
Xanthorrhiza apiifolia.

Vines, self-clinging.

*Evonymus radicans var. vegeta.
Hedera Helix.
Parthenocissus quinquefolia,*P. tricuspidata.

Vines, upon supports.

*Akebia quinata.
Campsis chinensis.
*Celastrus.
*Clematis in variety.
*Lonicera Halliana.
*Roses.
Wistaria.

Arthur W. Cowell.

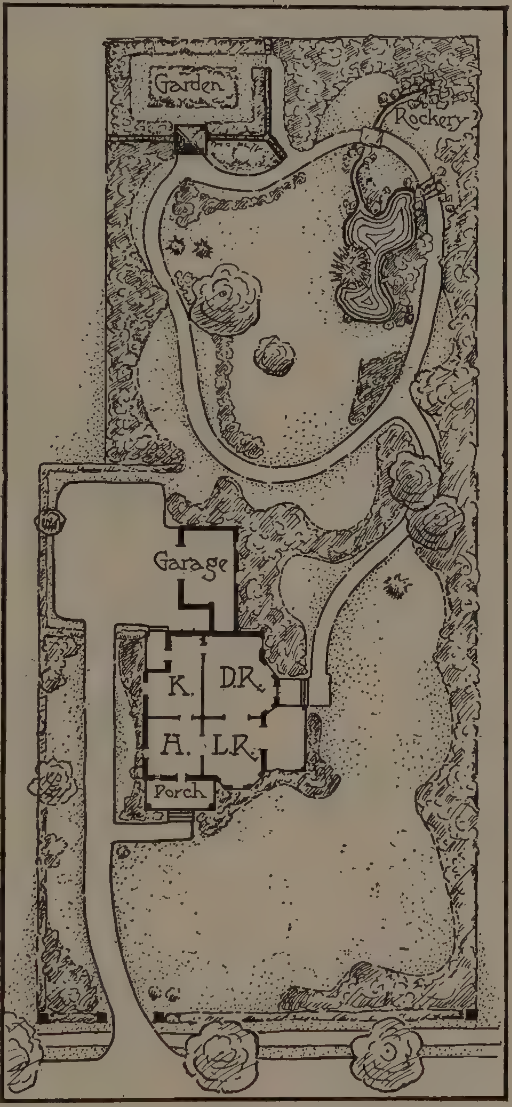
The landscape treatment of parks.

Parks are tracts of considerable size set apart primarily for enjoyment. Originally, in England, a park was a place for the preservation of deer for the chase, hence the word is often used to denote the landscape character commonly associated with such deer parks, which during the eighteenth century came to be managed much more for the sake of their landscape beauty than for deer-hunting. As a type of landscape, the deer park is characterized by comparatively broad stretches of pasture lying between irregularly and rather widely spaced masses of tree foliage. It is extremely simple and quiet in character, and while it often contains many other elements, such as ponds or running water, thickets of bushes under the trees or occasionally outstanding, or artificial structures such as drives, bridges or appropriate buildings, these features are all subordinate if the scene can be called typically park-like.

Private parks attached to country houses, in America, are usually so called because they have, or are intended to have, something of this park-like type of scenery (Figs. 2098–2102). A place departing very widely from this type is called, according to its character, a wood or grove, a garden, a farm, or more vaguely by the general term of country-place.

Public parks.

Public parks (Figs. 2097–2102) are so called, not because their scenery is necessarily of the type properly associated with the word "park," but because the Royal Parks were open to the people of English cities at the time when they began to feel the need of making municipal provision for the outdoor recreation of their growing populations. The earliest important pleasure-grounds created by cities having been modeled after these Royal Parks were themselves called parks, and the term was gradually extended to apply to almost any tract of land set apart for public enjoyment, regardless of the kind of enjoyment or the character of its scenery. But the best usage appears to confine the meaning of public park to a tract of considerable

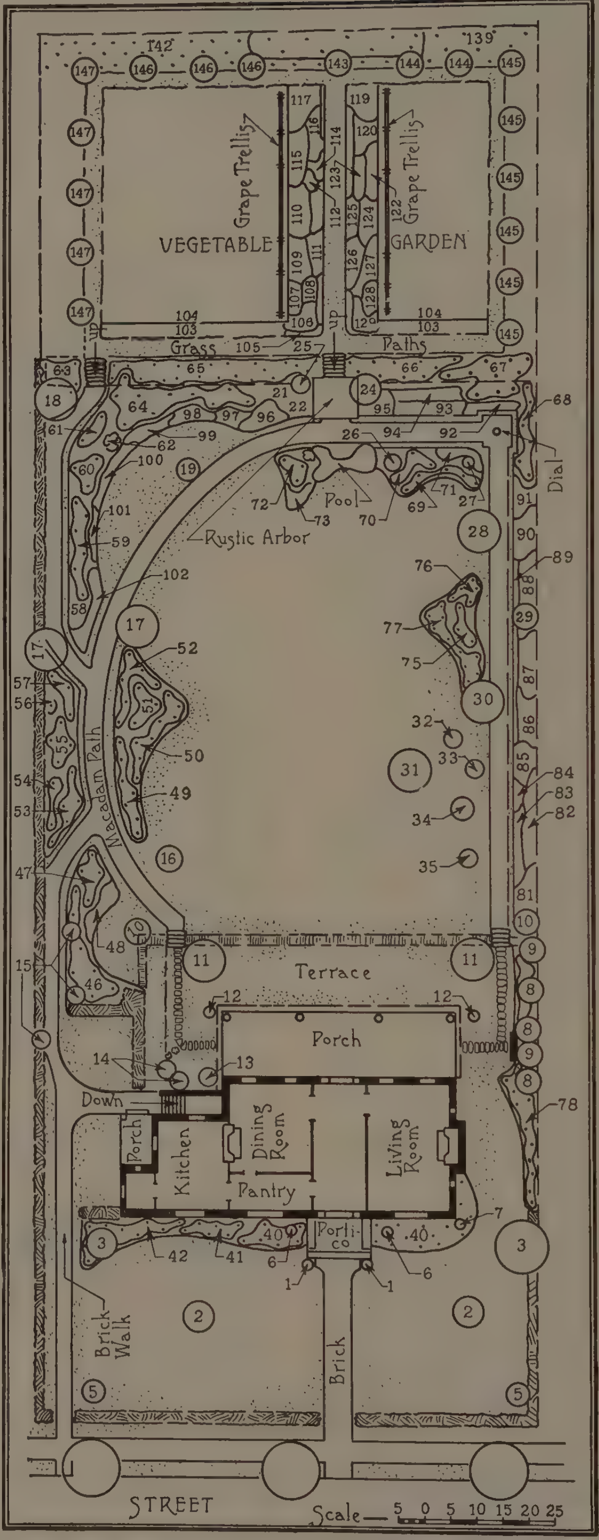


2094. Outline subdivision of a residence site. Pages 1797–1800.

size, leaving the lesser spaces to be called squares, gardens, playgrounds, places, and so on. Another special use of the word in America is its application to tracts of land in the West, many square miles in extent, either set apart by the government, as Yellowstone Park, or naturally distinguished by the presence of comparatively gentle grazing-land in the midst of rougher country. "Park" is also used in a more general way to indicate the general purpose of any open land devoted to public recreation, or of the organization controlling it, as "park system," "park department," and the like.

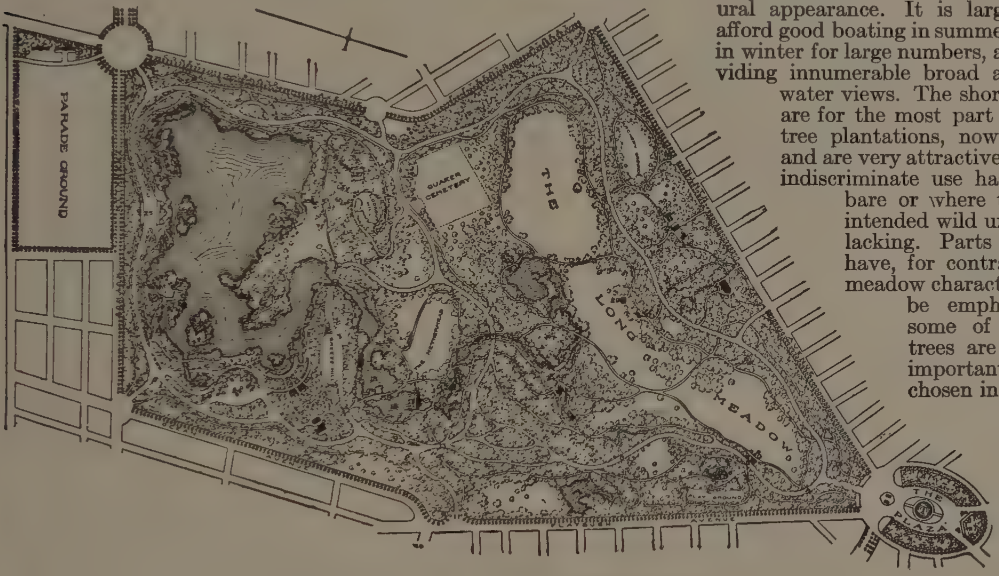
A large city park system usually contains parks of varying size and character and many smaller pleasure-grounds. No rigid classification can be made, but the following may be regarded as reasonably distinct types, each having its own field of usefulness, its own merits, and its own limitations. In practice, the lines between these types cannot be distinctly drawn, but poor results are often due to losing sight of the distinct and often conflicting motives which have given rise to these types.

1. *The large rural park* (Figs. 2096, 2099, 2100), generally from 200 to 1,000 acres, is in most cases the chief feature of a city park system. It is seldom undertaken except by large cities or cities so rapidly growing that the need of such provision can be clearly foreseen. Its main object is to provide conveniently in some degree for the inhabitants of large cities that sort of recreation which is to be obtained by strolling or driving in a pleasant country district. There is no doubt that the enjoyment of beautiful natural scenery is to most city dwellers one of the most refreshing antidotes for the wearing influences of crowded city life. When cities are of moderate size and are surrounded by a beautiful country district, this enjoyment is readily accessible to the mass of the population and it has fortunately become more so in proportion to the size of the cities within the generation embracing the transition from the nineteenth to the twentieth century, through the development of trolley car lines and the use of the bicycle and the automobile; but this increased accessibility of the country has been in part offset by the growth of the cities during the same period, and by the serious impairment of the rural quiet of the suburban regions through the same cause—improved cheap transportation. It is therefore necessary, if the people of large cities are to have easy access to refreshing rural scenery, that the municipality should withdraw from its taxable area a tract sufficiently large to provide such scenery within its own limits. The cost, both directly in money and indirectly through interference with the street system and with the normal commercial development of the land, is necessarily very great, and only the purpose of providing beautiful scenery, thoroughly contrasting with the city life and measurably sequestered from all its sights and sounds, can justify this cost, because almost all the other purposes served in public recreation grounds can be met more economically and far more conveniently in smaller areas distributed at frequent intervals throughout the city. The essential characteristics of a well-designed and well-managed park of this class are, therefore, that all of the numerous other objects which it may serve are subordinated to the provision of beautiful scenery and to rendering this scenery accessible and enjoyable by large numbers of persons, and that the



2095. Completed plan ready for execution, developed from a sketch plan. The numbers refer to a planting-list which should accompany the plan. Pages 1797–1800.

subordinate objects are met only in such ways and to such a degree as will not interfere with the simplicity and the rural and natural quality of the scenery.



2096. Plan of Prospect Park, Brooklyn, to illustrate the large rural park.

Prospect Park, in Brooklyn, begun in 1866, is here described in some detail for the purpose of affording a concrete example of the principles that the writer wishes to illustrate respecting rural parks. (Fig. 2096.) It has an area of 526⅙ acres. Its main entrance is about 3½ miles from New York City Hall, or 1¾ miles from Brooklyn City Hall. It is approached from the city by four lines of trolley cars, but is at the city end of the Parkway System, so that it must be reached through ordinary streets. The chief features of its design are: (1) the open, park-like landscape of the Long Meadow; (2) the woodland section, hilly and rising to an elevated outlook; (3) the lake and its surroundings; (4) a series of minor passages of scenery and elements of interest fitted in at points not appropriated for the main effects. The most characteristic and most valuable part of the park is the Long Meadow with its surrounding masses of wood, from the shade of which the outlook ranges over one of the most beautiful and simple park landscapes in the country. But one is not brought directly to the Meadow from the outside streets. One goes at first through a formal plaza, then through a retired shady ante-chamber, just long enough to give a sense of retirement from the city, then, if on foot, through an archway under the drive that does away with the nervousness of crossing a throng of vehicles, and then one comes out suddenly upon the joyous, sunny greensward. Its extent—over 50 acres—is enough to secure an effect of breadth and enlarged freedom without bringing its whole expanse into a single view. One can see that it reaches beyond the projecting groves and scattered trees that form the background of the main composition, and he is tempted to stroll on and open up the prospects thus suggested. The surrounding groves are freely used for picnic parties, and although much of the ground is trampled bare beneath the trees, but little serious harm is done. A carrousel or merry-go-round with its loud, mechanical organ, the only discordant feature of the place, was removed to this point a few years ago. This piece of apparatus was originally located in a retired section devoted to children's games, where all sorts of amusement apparatus might be placed without intruding on the park at large. The children's playground, not being shady or attractive for its purpose, has now been transformed into a rose-garden. On the lower edge of the Long Meadow are the pools which are at the source of the park ornamental water system. They illustrate both the value of water in a park landscape and the practical difficulty of securing and maintaining agreeable natural shores within the confines of a large city. Where the banks are clothed with shrubs the effect is admirable, but wherever the grass-land comes to the water's edge and in many places where shrubs once grew, the ground has become foot-worn to utter bareness. Adequate policing and prompt repair of points that cannot withstand too free use should never be lacking in all city parks. Leaving the Meadow, the water flows down through a ravine in the woodland portion of the park wholly overshadowed by trees with a varied undergrowth. Through this woodland section the paths and drives are comparatively narrow, numerous and intricate, as befits the intricacy and detail of sylvan scenery, and points of special interest are marked by simple rustic seats, shelters, outlooks, and the like. In the southern part of the park is a lake 62 acres in extent, of artificial formation, but of natural appearance. It is large enough to afford good boating in summer and skating in winter for large numbers, as well as providing innumerable broad and beautiful water views. The shores of the lake are for the most part wooded with tree plantations, now well grown, and are very attractive except where indiscriminate use has worn them bare or where the originally intended wild undergrowth is lacking. Parts of the shore have, for contrast, the open meadow character, which will be emphasized when some of the planted trees are cut. Several important points were chosen in the design of the park as places for the gathering of large and dense crowds, and were planned with that end in view. The first of these was the concert grove near the east end of the lake. The great breadth of bare ground or pavement unavoidable wherever large crowds gather frequently, makes absurd any attempt to simulate natural scenery in such a place, and in the design of the concert place a grove of formally planted trees with architectural accessories was made upon gently rising ground, arranged radially at one side of a little bay in the lake, upon an island in which the bandstand was to be placed. Upon another side of the bay a large concourse for carriages was also provided, and in connection with the formal treatment of the concert-grove was built a shelter, a restaurant and a terrace overlooking the main drive. While the grove was still so young as to be unattractive, a bandstand was erected in a natural grove near the Nethermead, a place in which the intricate woodland scenery with its brook and pools and shrubbery, and the correspondingly intricate arrangements of narrow paths and bridges, bridle-path and drive, were unfitted for accommodating a large crowd. Here the people are now drawn in thousands, on foot, on bicycles, in automobiles, and on horseback, all tramping about together, making bare earth where the grass and bushes once grew, and blocking the narrow bridges. The unused concert place now has a display of bedding plants. The second gathering-place was at the top of Lookout Hill, which rises 100 feet above the surrounding country and commands a noble view extending out to sea. Here is a large carriage concourse, although a shelter and other provisions designed for those on foot were never built. The plantations upon the flanks of the hill have become so high and so continuous that the views are nearly closed. A third point, the Breeze Hill Concourse, which originally enjoyed a good view of the lake as well as a good breeze, is no longer attractive as a viewpoint because of the growth of surrounding trees, and has been planted with perennials, as a Colonial Garden. Of the other subordinated features of interest may be mentioned the Deer Paddock, the Wild Fowl Pond, the Vale of Cashmere, the Archery Grounds and the Greenhouses. The space set apart on the plan for a Deer Paddock is a detached open area of suitable park-like kind; this land is now used as a tree and shrub nursery, and the deer have been transferred to unsuitably steep and broken ground in the midst of the woodland section. The Wild Fowl Pond is in such a situation that there is little temptation to go down and injure its steep banks by walking along them, and the effects of the views from path, road and shelter across its surface to the picturesque foliage of its opposite margin are admirable, especially when it is enlivened by moving birds. The Vale of Cashmere is a narrow valley containing a little winding pool and filled with a rich and varied massing of rhododendrons and other flowering shrubs and evergreens, growing in an irregular and picturesque manner. However a visitor may be impressed by any of these special features, he need see none of them that he does not particularly care for, as they are all self-contained and do not obtrude themselves upon the dominant park landscape, for the sole object of securing which the limits of the park were extended to their present size.

2. *The small city park* (Fig. 2097), from 10 to 200 acres or thereabouts, is usually an effort in the same general direction as the large rural park, with a limitation fixed by the difficulty of setting apart a large body of land in one piece at a point of access to a large population. It is almost impossible to attain within so small a space the degree of seclusion from the city and the sense of breadth, simplicity and freedom that are the essential features of the landscape of a rural park; yet small passages of interesting and agreeable scenery are often attainable, and the obviously artificial objects which may intrude upon them can often be so treated as to produce a harmonious effect. The scenery can seldom be quite natural in appearance, but it can often be very beautiful, a certain elaboration, elegance and even magnificance taking the place of the more quiet and restful simplicity of a large park, in a way that appeals so obviously to many persons that there is more or less tendency to develop large parks in the same direction. It is unfortunate that it should be so, for, as these ends can be attained almost as well upon small parks as upon large, it is clearly a mistake to treat one large park in this style instead of several of smaller size so distributed as to serve conveniently a larger population. It is because more cities have small parks of this elaborate treatment than have large and simple rural parks that so many persons have a perverted conception of what constitutes a park.

Morningside Park, New York, is an example of a small city park upon an extremely rugged and picturesque site, planned, in order to enhance this quality, with an avoidance of decorative elaboration. It occupies a craggy hillside strip from 250 to 500 feet wide and ⅔ mile long, with a difference of elevation from 50 to 100 feet between one side and the other, rendering the land unfit for streets or buildings. From its situation, as well as its narrow shape, it is essentially unsecluded; indeed one of its most notable features is the impressive and utterly unrural view which it offers over the busy streets and houses that stretch away from its base. This view and the boldness of the crags is emphasized by a stone terrace along the upper edge, supporting a promenade and a tree-lined boundary street. Convenience of passage is met by numerous broad paths, with masonry steps fitted to the irregularities of the ledges. The planting among the ledges was designed to be of the wild sort such as often clothes broken ledges naturally, while the more level land at the base of the crags is treated by contrast as a smooth lawn, with scattered trees. The natural boldness of the crags is partly lost by an effort to extend turf over every possible area, and the shrub planting is possibly rather too garden-like in style to be in entire accord with the situation, but in general the park is treated in a manner approaching that of the large parks, although without any attempt at complete rural seclusion. It contains a little over 30 acres, exclusive of the boundary streets and promenades.

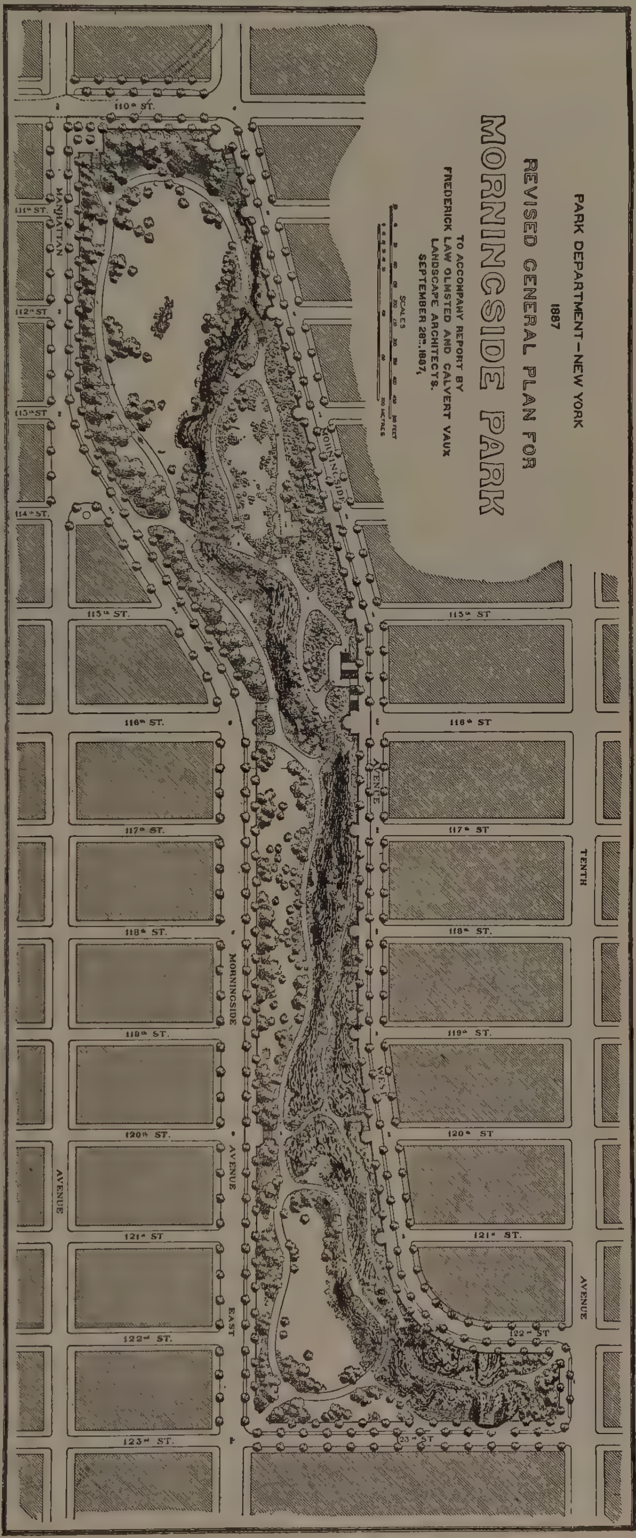
More commonly, small parks are used for the display of interesting and showy flowering shrubs and trees, and make a feature of fountains, statues and other sculpture more or less good. In moderation and skilfully used, such objects, are entirely appropriate and desirable in parks of this class, and add much to the effect of elegance and richness. The enjoyment is more closely related to that offered by architecture and decorative design and other pleasures forming a part of the daily city life.

3. *Neighborhood pleasure-grounds* are spaces of varying size coming within the scope of the park system, and including numerous aims other than the enjoyment of scenery. Sometimes the leading feature is a playground for athletic sports, sometimes a sort of outdoor kindergarten for little children, sometimes a concert grove and promenade, sometimes a menagerie, sometimes a public bathing-place or bowling-place. The area is usually restricted, and, as the name indicates, the object is to offer the maximum of outdoor recreation for the people of a single neighborhood, when they have not the time to go far afield. As children out of school hours are most in need of such provision, playgrounds form an important feature in many grounds of this class; but in all the best examples the means of meeting the various practical requirements, whether athletics, band-concerts or what not, are so arranged as to produce a pleasing effect on the eye as well. This is the more difficult from the fact that these grounds get very hard usage, and it is practically impossible to maintain a respectable turf on the area devoted to a playground, which is sometimes left in loam with grass worn bare in streaks and patches by the playing, but it is better surfaced with well-compacted gravel. So far as any single example can represent this class, which must vary in every element with local conditions, "Charlesbank," in Boston, opened in 1883, may be taken as an illustration. This playground occupies a tract of about 10 acres upon the borders of the Charles River at a point near a district of considerable congestion, and occupied by a population of a poor class. A promenade was established on the edge of the sea wall about 2,000 feet in length, and between it and the street a playground was laid out, having an average width of about 250 feet. Within this long, narrow belt of public ground were established two outdoor gymnasia, each with a running-track and a building for dressing and bathing. One of these outdoor gymnasia was designed for women and children and the other for men and boys, and they are at the opposite extremities of the playground. The tract between them was laid out with walks, trees, shrubs and turf, and was intended primarily to appeal to the esthetic senses. The "Charlesbank" has well proved the practicability of maintaining, within the very heart of the city, a tract of ground occupied by greensward and trees, despite the fact that it is frequented by

thousands of men, women and children. The city of Boston provides free instruction in gymnastics upon the playground, and yearly over 70,000 women and girls, and 200,000 men and boys have made use of the facilities offered. The total cost of this playground for land and improvements was $382,000, and the yearly cost of maintenance is $10,000.

4. *Squares, places, gardens,* and the like, usually of small area, are scattered about a city, often at street intersections. Their principal functions are to furnish agreeable sights for those passing by them or through them in the course of their daily business, and to provide a pleasant resting-place or promenade for the much smaller number who take the time to use them so. Because of the almost constant passing through such squares, the best arrangements all provide for reasonably direct and convenient paths along the lines most used (see Fig. 2083). Otherwise, manyof those who use the square are likely to be so irritated by the indirectness as to miss much of the pleasure they might otherwise receive. A formal plan of walks, either on straight lines or curved, is generally adopted for such squares, and is well suited to the conditions and to the decorative treatment of the area, providing much more effectively than an irregular plan for the statues, fountains, and gay flower-beds which have their most appropriate location in such a place. Shade trees, either as a complete grove, or in rows along the paths, or grouped in some more complex plan, are almost essential features of such squares, but where displays of flowers are to be made, open spaces must be left for sunlight. A modification of this type of square is sometimes met with where the space, instead of being used as a short-cut and for enjoyment from within, is designed primarily to present an agreeable picture to those passing it upon the adjacent streets. When the area is very small and the passing is almost wholly along one side, and in other special cases, this treatment is most effective, because, where the only aim is a beautiful pictorial effect from a limited point of view, better results can be obtained than when appearances must be reconciled with other uses of the land. Nevertheless there are few cases in which a small square will not have a greater recreative value to the public if its pictorial aspect is somewhat sacrificed to such uses as resting and promenading.

5. *Parkways and boulevards,* as parts of a park system, serve usually as pleasant means of access to parks from other parts of the city, or from one park to another, and also as agreeable promenades in themselves. Commercial traffic is usually excluded from them. Boulevards are arranged formally, usually upon straight lines, with rows of shade trees and parallel ways for those on foot and on wheels. The simplest type has a broad drive in the center with a walk on either side separated from the drive by a belt of turf and it is always shaded by trees. Frequently, two driveways are provided with a broad space between containing trees and turf, and sometimes foot-paths, bicycle-paths, bridle-paths or other conveniences, and often shrubs, flowers, statues and other decorations. A further development is arranged like the first form, with the addition of narrow streets for house frontage on each side, sometimes with a widening and elaboration of the planting-spaces between the middle drive and the side roads. Of recent years some boulevards have been made to provide for electric-car



2097. Plan of Morningside Park, in the upper part of New York City, to illustrate the small city park.

tracks upon a special turfed reservation with rows of trees, thus enabling the cars to be run at high speed with little danger of collision with other vehicles. Such reservations are generally between two roadways, but in some suburban districts, notably in the city of Rochester, a single track reservation is placed on either side of a single roadway, between the curb and the sidewalk. A parkway, so far as it can be discriminated from a boulevard, includes more breadth of turf or planted ground and includes, usually, narrow passages of natural scenery of varying width, giving it a somewhat park-like character and inducing a less formal treatment of the roads, paths, and accessory features. Parkways are frequently laid out along streams so as to include the natural beauties of brook or river scenery and to preserve the main surface-water channels in public control, thus providing for the adequate, economical and agreeable regulation of storm-drainage and floods.

6. *Outlying reservations* of almost undeveloped country scenery, usually from 500 to 5,000 acres in extent, are wisely included in the park systems of some of the larger cities on account of the increasing difficulty of reaching the unspoiled scenery of the open country, and because, otherwise, the increasing numbers of persons seeking such scenery upon the outskirts of the suburbs secure their pleasure at a constantly increasing discomfort to themselves and to the private landowners upon whose property they are forced to trespass. The most notable of such reservations in America are those of the Boston Metropolitan District, comprising four forest reservations with a total area of over 10,000 acres, with 33 miles of connecting parkways. The most notable of such reservations in Europe are those of London, especially Epping Forest (5,346 acres) and Richmond Park (2,358 acres); and those of Paris, amounting to about 20,000 acres, chiefly maintained, not by the city, but by the national government.

Management.—The usual and best method of managing city parks is by an unpaid commission of three or five members appointed for terms of three or five years and retiring successively, with a view to continuity of policy and independence of local politics. Of late, a strong movement for municipal efficiency has led to placing the park department of some cities in charge of a single commissioner who is chosen for his business ability rather than for his cultivated taste. This is a great mistake. Business efficiency in park management is important but should be secondary to the main purpose of attaining and preserving landscape beauty in the large parks and the avoidance of freakishness in all the parks. The single park commissioner is dangerous because he has the power and the instinct to order the immediate execution of any personal notion or whim, whereas a board instinctively desires to discuss new projects and has to be persuaded of their merit and wisdom before it will vote for them. In creative art the best designing is personal, but in maintaining works of art a consensus of opinion is much safer. The commission appoints as executive officers a secretary and a superintendent, the latter having some technical skill, and each devoting his whole time to the work and receiving a salary. Under the orders of the superintendent, who receives his instructions direct from the board, are employed an engineer, local superintendents, gardeners, foremen, and so on. The engineer is generally an assistant of the city engineer, assigned temporarily to park work. When new parks are to be acquired or plans are to be made for their development, a professional landscape architect is employed to advise the board and to make plans, and is usually retained at least in a consulting capacity during the period of construction. Some large cities retain a consulting landscape architect permanently to advise them with regard to questions of improvement and maintenance affecting the design of the parks.

Statistics.—Reliable statistics of parks are almost unattainable. The accompanying incomplete compilation has been corrected to 1914, except a few items which are starred.

Name of city	Large parks and parkways	Acreage	Other spaces	Acreage	Total acreage	Total appropriation and cost	Population, 1910	Cost per capita	No. inhabitants per acre

F. L. Olmsted.

Landscape cemeteries (Fig. 2103).

The cemeteries of the present day have come into existence from a desire to have burials made at a distance from centers of population, and among beautiful surroundings. They are often called "rural cemeteries." The first one in the United States to merit this name was Mt. Auburn, near Boston, Massachusetts, founded in 1831. Since then the idea of having burial-places park-like in their character has been spreading until they contain today some of the most beautiful landscapes developed by the hand of man. The wish to have in the cemetery the beauty of trees, shrubs, lawns and flowers has gradually led to the abolition of fences, coping and other lot enclosures, and a reduction in the number of monuments and the size of headstones. There are many who now believe that the last resting-place should be surrounded by the quietness and beauty of these features of nature's handiwork without distracting stonework or artificial objects. There are others who say that "the cemetery should be a cemetery," meaning by this expression that it should resemble somewhat closely the old conventional churchyard or graveyard, with its multitude of crowded tomb-stones inscribed with the names and good qualities of those buried within its walls.

All agree that the cemetery should be so situated and maintained as to menace in no way the healthfulness of surrounding neighborhoods. The ideal location is one where the ground is somewhat undulating and thoroughly drained by having a porous subsoil, while the surface soil is sufficiently rich and deep to support a good growth of vegetation. In some instances, as at Forest Hills, Boston, and at Woodlawn, New York, it has been necessary to blast and remove rock and then fill in the space with earth. In other cases, the natural soil has been so poor that it has been necessary to cover it with rich earth hauled from a long distance. In still other cases, it has been necessary to select a clay soil because there was no other, or to make ground by excavating lakes, using the material excavated to raise the surrounding land, or to inter above ground in structures erected for the purpose, as at New Orleans.

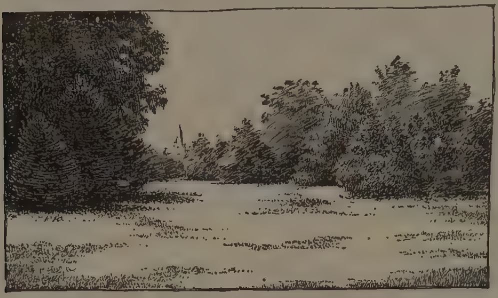
When a site is chosen, it is usually subdivided into sections and lots, which must be made accessible by the construction of drives and walks. A drive should pass within about 150 feet of every place available for burial. The width of the roadways should vary according to the size of the cemetery and the probable amount of driving. If the area is very small, not over 4 or 5 acres, it may be unnecessary to have any road or drive. In a little larger area, a grass drive 8 feet wide might suffice; in one still larger, a driveway 16 feet; and, finally, a cemetery designed to accommodate large populations should have good roadways 24 to 32 feet in width. Formerly these roadways would have been made of ordinary macadam or gravel, but with the increased use of automobiles, the material used for roadways should be bitulithic concrete, bitulithic macadam, cement concrete, or brick, preference being given to the first.

Walks should generally be left in grass and form part of a continuous lawn, such walks being better in appearance and more easily maintained than those made of gravel. The location of the drives will determine the shapes and sizes of the sections. The plans should be made after a careful study of the ground in question, the drives being placed so that they will have easy grades, command good views, and be as few as possible while being approximately 300 feet apart. When the ground is irregular in shape, or has steep slopes, or contains streams or lakes or valuable trees, these features may make it necessary to construct more drives than would otherwise be needed. They can generally be staked out on the ground by eye with a better effect than if drawn first in an office by the use of some geometrical curve. They should nearly always be curved to produce the most pleasing result, a curved driveway being advisable because: (1) when the margins are properly planted certain portions of the ground are always hidden; thus becoming more interesting; (2) they insure varied effects of light and shade; (3) they make the average distance from the cemetery entrance to the lots shorter than if one follows straight lines and turns right angles.

2098. Entrance to an American residence park. Page 1801.

An open tract, to begin with, is in many ways preferable to one that is thickly wooded, but groups of trees or single specimens that have broadened out in a natural way would be very valuable, since they would help to take away the naked, forbidding appearance of land newly planted with young trees. On a vacant area, it is usually advisable to plant some large trees for the sake of immediate effect. These can be grouped about the entrance, a fork in the drives, the top of a hill, the margin of a lake, or other distinguishing position. The objection to a piece of land covered with thick woods is that the necessary thinning to get sufficient open space will leave tall, spindling trees, unused to exposure. These are not very attractive in themselves, are very likely to die and are liable to be blown down. If there are thick woods in the land chosen, the trees chosen to remain should be those that are healthiest and have the lowest branches. Some of the trees removed might be cut off at the ground, when the sprouts springing from the stump will form beautiful bush-like specimens.

The necessary buildings will vary with the size of the cemetery, but they should always be modest in appearance and suitably embellished with shrubbery and vines. The office would naturally be placed near the entrance to avoid unnecessary walking, but it should not be built immediately on the highway or public street. The large arch frequently built over the gateway is usually too pretentious in appearance and not in keeping with the character of the grounds. A natural archway of living trees would be better. The chapel, if any, should be placed some distance within the grounds to give it greater seclusion and quietness.



2099. Vista in a large rural park. Page 1801.

Whether there should be greenhouses or not cannot be discussed here on account of the limits of this article. It may simply be said that with the great variety of flowering trees and shrubs which we have to choose from, as well as the thousands of hardy flowering herbaceous plants, most beautiful effects can be produced without the expense, the continual labor and the bare beds more than half the year, which would follow the construction of greenhouses and the use of bedding plants. Usually the selection for planting of material found growing in the adjacent country will help produce satisfactory results with little expenditure of money and time. To prevent intrusion, a fence along the boundary of the cemetery is necessary, but this can be a simple inexpensive wire fence, serving in places as a support for vines, and in places being hidden by a belt of trees and shrubbery. No one would now make the cemetery dreary by confining the planting to spruces and weeping willows. On the contrary, every effort is made to secure bright cheerful effects by the selection of all kinds of flowering happy-looking plants. The modern cemetery becomes, in fact, a sort of arboretum. It includes some evergreens which are most suitably grouped along the boundary belt, and which should contain all kinds of hardy pines, as well as some of the more stiff and formal spruces. The planting of Norway spruces has in many places been overdone. The development of attractive landscapes in cemeteries is of so much importance that Mr. Strauch, the greatest cemetery designer that we have had, used to call the present method "the landscape lawn plan."

2100. Water scene in a large rural park. Page 1801.

A good landscape in the cemetery is usually the result of years of growth. It must first be intelligently designed, and then receive care and attention from someone familiar and in sympathy with the scheme adopted. To insure such attention, and to protect the interest of all lot-owners, as well as to maintain the dignity and character of a city of the dead, rules have been adopted by all leading cemeteries. These rules are the result of study and experience on the part of many men. At a meeting of the Association of American Cemetery Superintendents, held at Boston, in 1890, the following rules were recommended by a unanimous vote of those in attendance:

Rule 1. (This should be a general rule, stating the authority and conditions on which lots are sold and the restrictions on transfers. The rule, of course, would have to be varied according to conditions existing in each cemetery.)

Rule 2. The trustees desire to leave the improvement of lots, as far as possible, to the taste of the owners; but, in justice to all, they reserve the right, given them by law, to exclude or remove from any lot any headstone, monument or other structure, tree, plant, or other object whatever which may conflict with the regulations, or which they shall consider injurious to the general appearance of the grounds; but no trees growing within any lot shall be removed or trimmed without the consent of the trustees.

Rule 3. Lot-owners may have planting or other work done on their lots at their expense, upon application to the superintendent. No workmen other than employees of the cemetery will be admitted to the cemetery except for the purpose of setting stonework.

Rule 4. No iron- or wirework and no seats or vases will be allowed on lots, excepting by permission of the trustees, and when any article made of iron begins to rust the same shall be removed from the cemetery.

Rule 5. The trustees desire to encourage the planting of trees and shrubbery, but, in order to protect the rights of all and to secure the best general results, they require that such planting shall be done only in accordance with the directions of the superintendent of the cemetery.

Rule 6. No coping nor any kind of inclosure will be permitted. The boundaries of lots will be marked by corner-stones, which will be set by the cemetery, at the expense of the lot-owner, with the centers upon the lines bounding the lot. Corner-stones must not project above the ground and must not be altered nor removed.

Rule 7. No lots shall be filled above the established grade.

Rule 8. All interments in lots shall be restricted to the members of the family or relations of the lot-owner.

Rule 9. No disinterment will be allowed without the permission of the trustees, of the lot-owner, and of the next of kin of the deceased.

Rule 10. Mounds over graves should be kept low, not exceeding four inches in height; and stone or other enclosures around graves will not be allowed.

Rule 11. Foundations for all monuments, headstones, and the like, shall be built by the cemetery at the expense of the lot-owner and fifteen days' notice must be given for the building of foundations. The cost of the same must be paid in advance.

Rule 12. Every foundation must be at least as wide and as long as the base stone resting upon it, and must not project above the surface of the ground. All foundations must extend as low as the bottom of the grave.

Rule 13. Only one monument will be permitted on a family burial-lot.

Rule 14. (This should be a rule limiting the height of the headstones, and the lower this limit is made the better. Even with the lawn is considered best.)

Rule 15. All stone and marble works, monuments and headstones, must be accepted by the superintendent as being in conformity with the foregoing rules before being taken into the cemetery.

Rule 16. No monument, headstone or coping, and no portion of any vault above ground shall be constructed of other material than cut stone or real bronze. No artificial material will be permitted.

2101. Edge of the concert grove in Prospect Park.

Rule 17. The trustees wish, as far as possible, to discourage the building of vaults, believing, with the best landscape gardeners of the day, that they are generally injurious to the appearance of the grounds, and, unless constructed with great care, are apt to leak and are liable to rapid decay, and in course of time to become unsightly ruins. Therefore no vaults will be permitted to be built unless the designs for the same are exceptionally good, and the construction is solid and thorough. The designs must be submitted to the trustees, and will not be approved unless the structure would, in their judgment, be an architectural ornament to the cemetery.

Rule 18. Material for stone or marble work will not be allowed to remain in the cemetery longer than shall be strictly necessary, and refuse or unused material must be removed as soon as the work is completed. In case of neglect, such removal will be made by the cemetery at the expense of the lot-owner and contractor, who shall be severally responsible. No material of any kind will be received at the cemetery after 12 o'clock M. on Saturdays.

Rule 19. The trustees shall have the right to make exceptions from the foregoing rules in favor of designs which they consider exceptionally artistic and ornamental, and such exceptions shall not be construed as a rescission of any rule.

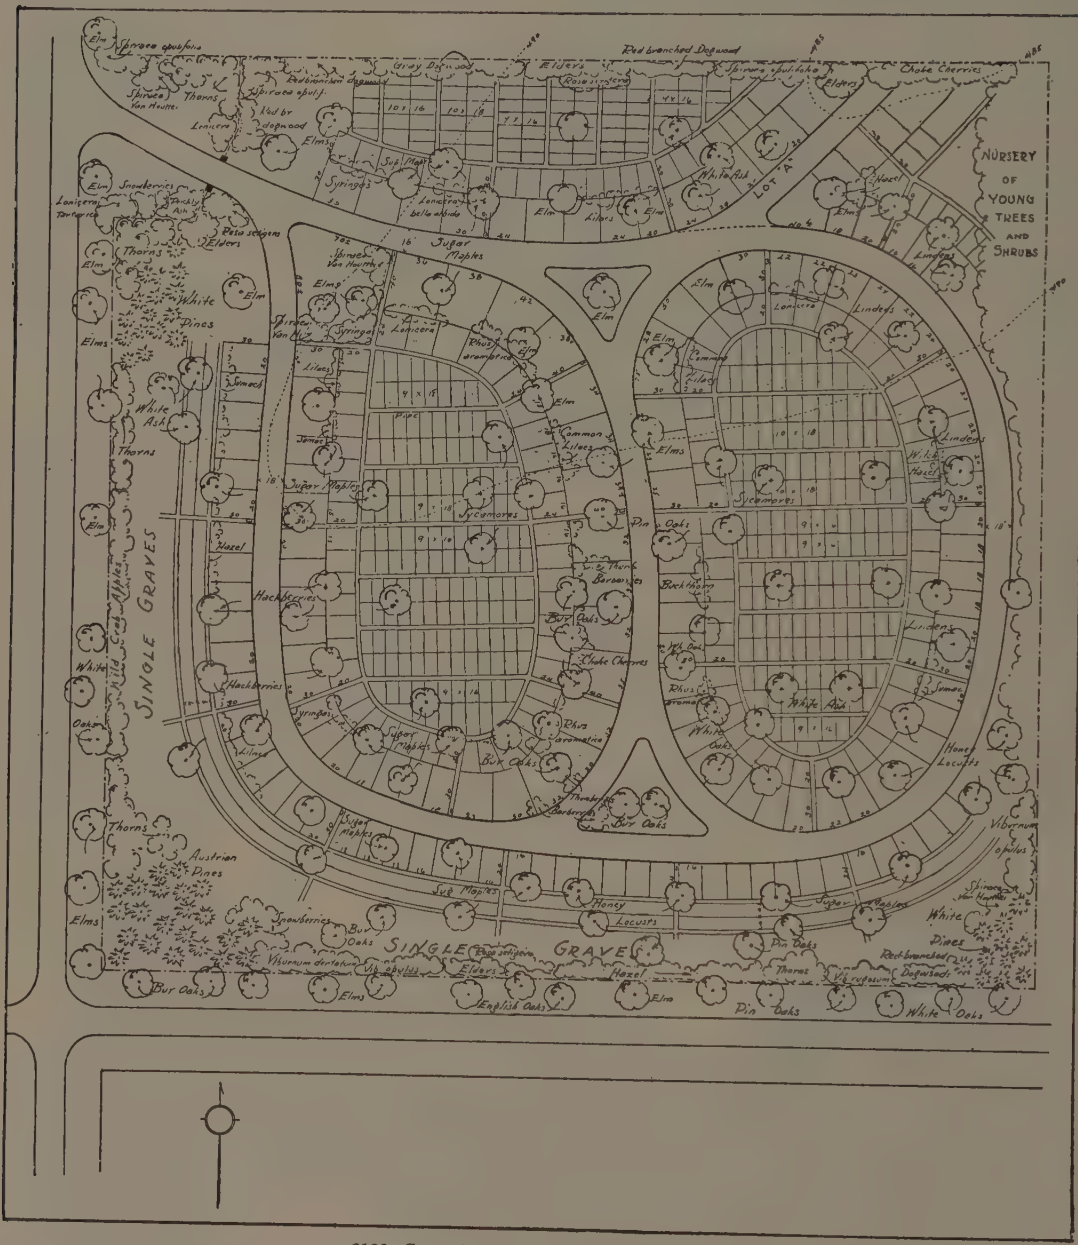
Rule 20. It shall be the duty and right of the trustees from time to time to lay out and alter such avenues and walks, and to make such rules and regulations for the government of the grounds as they may deem requisite and proper and calculated to secure and promote the general object of the cemetery.

Rule 21. The superintendent is directed to enforce the above regulations and to exclude from the cemetery any person willfully violating the same.

Cemeteries should be established upon a basis to enable those in authority to take uniform care of the grounds for all time. The prices charged for lots should be high enough to enable a fund to be set aside that will yield an annual income sufficient to pay all necessary general expenses. In laying out a new cemetery, those in charge should seek the best advice available. Such advice should be based on a thorough knowledge of landscape gardening and the special needs of burial-grounds. Much information can be obtained by visiting Spring Grove, at Cincinnati, Ohio, generally recognized as the pioneer of park-like cemeteries, and perhaps the

2102. A park-like effect in a private place.

best example in the world. Oakwoods Cemetery, at Troy, N. Y., Swan Point Cemetery, at Providence, R. I., and Forest Hills Cemetery, at Boston, are some of the prominent examples of the system now in vogue. Graceland Cemetery, at Chicago, although much smaller in area than those already mentioned, contains some good landscape effects. There are many other cemeteries in the vicinity of the large cities of the United States which can be commended on account of the good taste displayed in them. There are others which, while containing many beautiful trees and expensive monuments, include also many fences, railings, copings and hedges that serve as examples of what to avoid rather than to imitate.



2103. Ground plan of a landscape cemetery.

Our leading cemeteries should keep pace with the best thought of the times, with the best theories of religion, science and economics. They should be, as the name implies, sleeping-places—places of rest and freedom from intrusion. It seems natural that people should seek for such a place the very best production of landscape-art, a place where spreading lawns give a cheerful warmth and sunlight; where pleasing vistas show distant clouds or the setting sun; where branching trees give grateful shade, furnish pleasing objects to look at, and places for birds to come each year and sing again their welcome songs; where blossoming shrubs delight the eye, perfume the air, and make attractive nesting-places. Such places may seem to exist more for the living than for the dead, but the living are the ones that need them. If it seems natural to choose a most beautiful park, a real picture, we might call it, for a sleeping-place, it seems strange to put into this picture obelisk after obelisk, stone posts and slabs of all shapes and sizes, and stone tombs within whose walls their owners hope to have their dead bodies preserved forever. The history of sepulture shows the futility of trying to preserve one's body or one's name with the help of stone. A man can hand his name down to posterity only by his own work, and even if his body should be preserved as long as were those of the ancient Egyptians, it might finally be used only for fuel. These facts should be recognized in the modern cemetery. The ground should assist in changing the body back into inorganic forms or to receive the ashes, if the quicker process of cremation is adopted. The scenery should solace those that are bereft.

It is repugnant to our best feelings to use the same land over and over again, as is done in many cities in Europe and, to some extent, in the United States. A cemetery is frequently spoken of as the last resting-place, and it serves mankind best when it is so in fact, since in that case, after it has served its purpose of purification, it becomes a park, a breathing-place for the people of the city, whose growth is likely to crowd the vicinity with houses. The memory of past generations will certainly be sweeter if it is associated with trees than if it is connected with tombs, catacombs and pyramids. The problem presented to cemetery associations is, therefore, how to secure the most pleasing combinations of growing plants, including trees, shrubs, flowers and grass; the most satisfactory views; the most harmonious and restful park, for the cemetery is really a memorial park.

Those seeking information on this subject will find it in the reports and histories of the various cemeteries and in encyclopedias. The development of the landscape idea in connection with cemeteries is given in some of the reports of those institutions, that of Spring Grove, for the year 1869 being especially valuable. The reports of the Association of American Superintendents contain many papers of interest. The volumes of the "Modern Cemetery," afterward the "Park and Cemetery," the leading periodical devoted to the interests of burial-places, contain articles relating to all phases of the subject. All books relating in any way to landscape gardening are of value in cemetery work, since they treat of all its natural features. O. C. SIMONDS.

Horticultural phases of civic art.

It is the plan of this work to discuss horticultural phases of landscape gardening without entering upon questions of design. It must be said, however, that problems of structural design and orderly arrangement are much more fundamental and important to all phases of civic art than the mere ornamental horticultural treatment. This statement having been distinctly understood, we may proceed to discuss the horticultural phases of this subject which are indeed extensive and important.

Civic art may be somewhat accurately defined as the conservation, improvement, and utilization of public property. With negligible exceptions, civic improvement deals exclusively with public property or with property owned by quasi-public corporations; or, at farthest, with private property administered in the public interest.

The forms of public property in most common use are roads, town commons, parks, "squares," playgrounds, school grounds, church grounds, cemeteries, railroad station grounds, historic and scenic reservations, and forest reservations. Some horticultural treatment is requisite for the development of practically every one of these several types of public property. This means chiefly the use of trees, shrubs and grass.

Streets.

In all except the crowded business streets in mercantile and manufacturing sections of cities, street trees are considered desirable. Indeed some of the finest and most important business streets in the world are beautifully parked with trees and shrubbery; e. g., Unter den Linden, Berlin; and the Ringstrasse, Vienna.

The usual method of treatment is to plant a double row of trees, one on either side of the street, carefully alined with the street and regularly spaced. These trees in any certain section should be all of one species and of one age. As a rule these trees will be placed between the curbing and the sidewalk, though other arrangements are made in special cases. Wide boulevards and pretentious residence streets are sometimes planted with four rows of trees. In this case it is generally desirable for all of the trees to be of the same kind and age, though good effects are occasionally produced by having the two intermediate rows of an entirely different and contrasting species. Occasionally a narrow parking in the middle of a wide street may be planted with a single row of contrasting ornamental trees such as palms, magnolias, hawthorns or apples.

In many narrow streets it is desirable to plant a single row of trees which would usually be of some small-growing and very hardy species such as horse-chestnut or ailanthus. This single row should be placed just inside the gutter line on the north side of streets running east and west and on the east side of streets running north and south. (For species of trees suited to different sections, see Waugh's "Rural Improvement.")

In addition to trees, most streets need a strip of grass. Indeed the trees will not thrive unless there is some open planting strip where the soil is exposed, and this planting strip should practically always be kept in grass. These grass spaces should be of regular patterns—that is, they should not be cut to pieces by intersecting paths and roads—they should be evenly graded and should be kept well cut and trimmed.

In streets or boulevards where elaborate parkings are maintained, the horticultural embellishments may reach to almost any extent. A common treatment in continental Europe, but one hardly known in America, is the use of festoons of ampelopsis or clematis. In America, street parkings are commonly made up of shrubbery masses, sometimes interspersed with groups of hardy herbaceous material or even with cannas and other hothouse plants. The present custom is to arrange these parkings with marked informality. It may fairly be suggested that the character of street development would make a more formal treatment more effective.

Such shrubbery parkings should be confined to the most hardy and resistant species, such as spireas, barberries, the best viburnums, privets, and the like.

It hardly needs to be remarked that such parkings are expensive. They should not be undertaken except in circumstances where liberal treatment can be given. The initial cost of development, for parking alone, should run from $5,000 to $10,000 a mile; and the average annual up-keep from $2,000 to $3,000 a mile.

Country roads.

Tree-plantings along country roads are quite as desirable as along city streets, although the problem here is decidedly different. Some species of trees, particularly large-growing conifers, can be used on country roads which are not available for city planting. Some objection has been made at times to tree-planting for country roads on the ground that it prevents the road-bed from drying out, especially in springtime. This objection is somewhat captious and is not generally accepted. While it would seem undesirable to have all country roads everywhere planted with trees, it may safely be said that permanent plantings should be much more extensive than they now are.

In this connection it seems proper to notice a scheme which is frequently urged in this country, viz., the planting of country roads with fruit trees. One prime argument always advanced by the advocates of this plan is its successful use in Europe. Extended observation in all the countries of continental Europe convinces the writer that fruit trees along country roads are rather rare. Especially uncommon are examples of extensive municipal planting and maintenance of such fruit trees. At the same time Europe has certain definite advantages over America in enterprises of this kind. On the whole the plan seems generally impracticable in America. The exceptions to be noted are rows of apple trees rather frequently seen alongside of farm fields in New York state and New England. These are indeed very beautiful and a great addition to the public pleasure in the use of the roads. They are always held as private property.

Scenic roads.

Besides the planting of simple rows of trees along country roads, much more extended developments will be highly justified in many cases. First of all, the shrubbery borders along the roadside may be conserved and improved. Where such natural shrubbery borders do not exist, they may be planted and such plantings should be designed and carried out by expert landscape gardeners, seeing the work is of such general value. Numerous promising experiments have been made in the last few years in this direction of developing attractive roadside plantings.

Such public roadside plantings may properly become the conservation grounds of native species. It is a signal and unfortunate fact that in many parts of the country, especially where agriculture is particularly effective, many of the finest native species are rapidly disappearing. This applies to trees, shrubs and native herbaceous flowering plants. Many of these native plants are not noxious weeds in the ordinary sense. The weeds in fact are able to take care of themselves and do maintain their kind against the assaults of organized agriculture. Many shy and delicate species, however, of the utmost interest and beauty, give way quickly before the plow. These are the species which should be carefully protected by gardeners everywhere and which might with special propriety be encouraged along country roadsides.

Another similar service of the roadside plantings may be rendered in the conservation of native birds. These also, and especially the rarer and more interesting species, are disappearing before the encroachments of civilization. Some attention paid to the encouragement of birds in these roadside plantings would be highly justified on grounds of public policy.

There should be considered further the fact that the country roads everywhere constitute the most popular public parks in existence. The automobiles always take to the country roads, rather than to the city parks, from an absolute and almost universal preference. They find these roads more enjoyable than any other scenes. This suggests that the roads should have along many miles of their extent the same careful scenic treatment which is given to the scenery and plantings along park roads. This means not only skilful ornamental planting, but occasional cutting out of trees for opening up views, the removal of unsightly objects, the abolition of the roadside dump, and the subjugation of the billboard.

It may fairly be suggested further that in many parts of the country special scenic roads should be opened up, the main object of which is to develop stretches of fine scenery. These should in fact be laid on such indirect and circuitous lines as to prevent their use by business traffic. They would follow winding streams or the shores of lakes, or would climb over ridges of hills where the views were extensive. This is a type of landscape gardening not generally undertaken anywhere in the world, but one which seems especially suitable to the genius of America.

Care and protection of trees.

While it is always desirable to have more extended plantings of trees both in city streets and along country roads, the preservation of existing trees presents nearly everywhere a more immediate and serious problem. Street trees are subject to many kinds of damage. Aside from the usual insect and fungous enemies, they have to contend against bad soil conditions, against the inroads of telephone linemen, trolley companies, gas mains, electric light wires, and all similar public utilities which have learned to use the road for their private profit, and largely to disregard the public rights in tree property. The regulation of gas mains and electric wires is perhaps the most difficult, as it is the most common, problem of all. In general, every effort should be made to remove wires from streets, and where this cannot be done, to see that they are kept out of the tree tops and everywhere properly insulated and stayed.

In certain parts of the country, public trees are considered of such great value that their care has been turned over to a special officer, the tree-warden. Such officers should have definite and fairly extended powers. Their business is to enforce the legal rights of the public in the trees, and to protect them from the attacks of private interests as well as from the attacks of insects and fungi. The tree-warden may easily be one of the most useful public officers in a municipality.

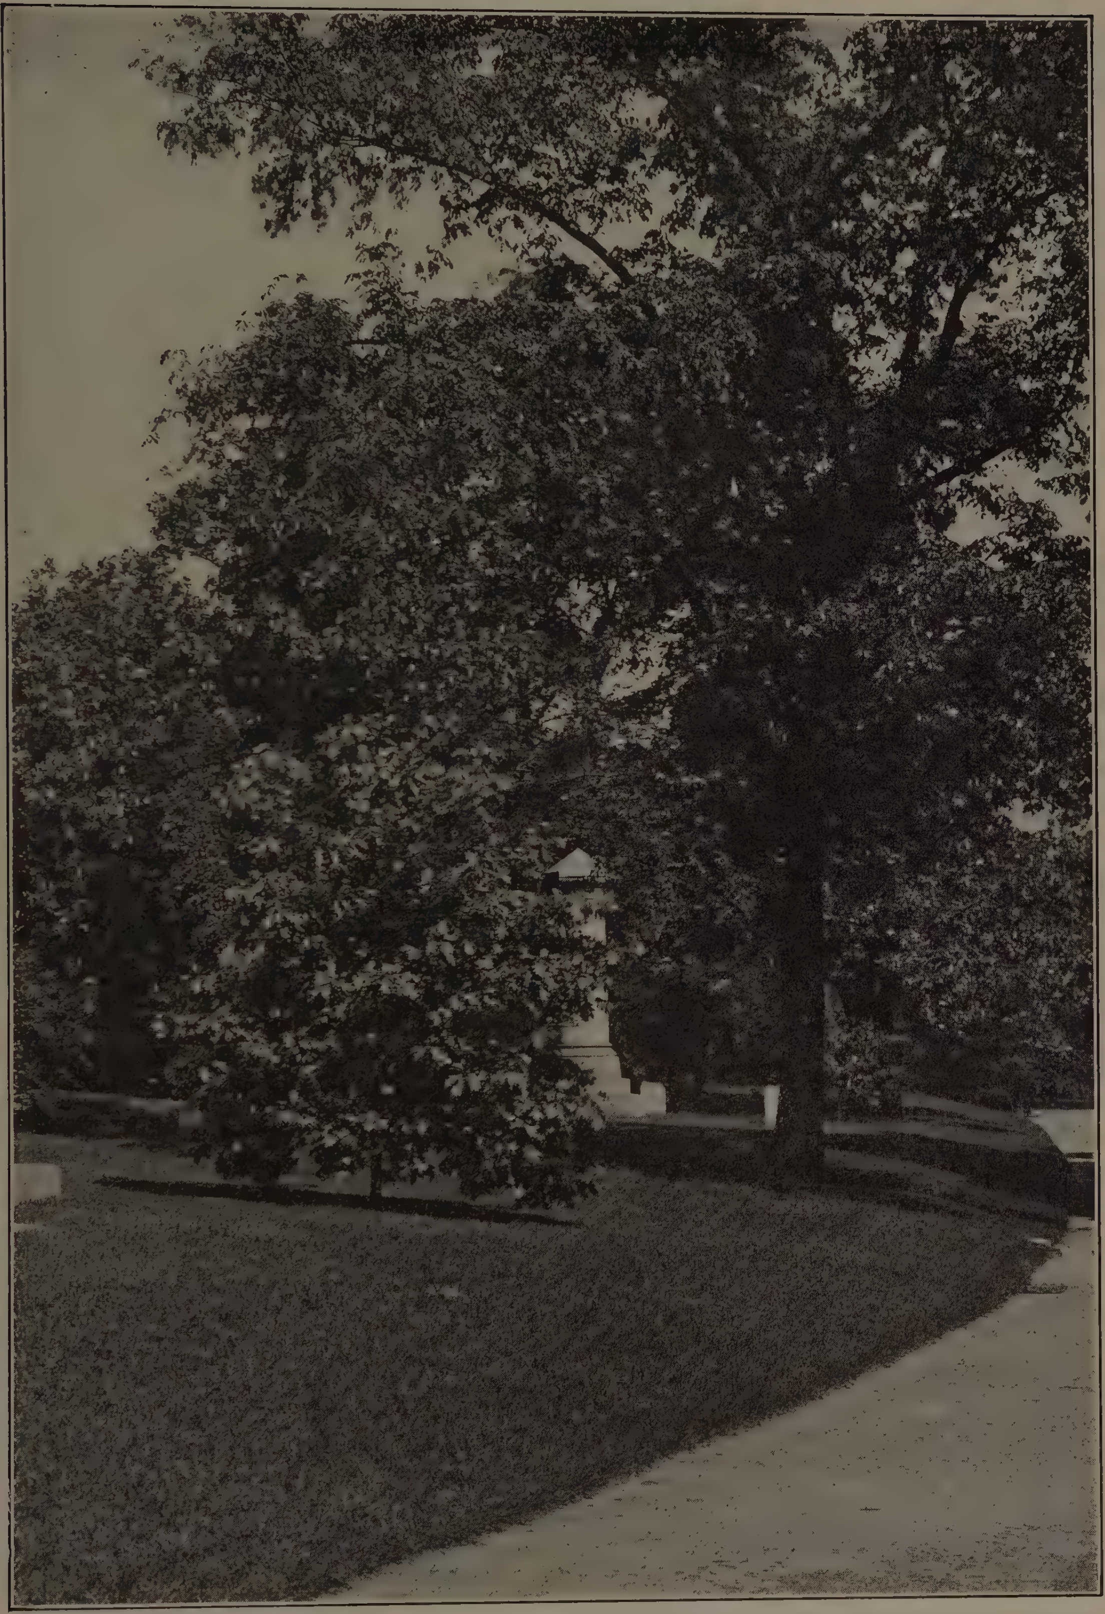
Along with an aroused public interest in trees, has arisen an army of "tree doctors," a considerable number of whom are low-grade quacks. Expert service in the repair and preservation of trees is everywhere to be encouraged, but very cautious discrimination must be exercised. It will not do to assume that the company getting out the biggest advertisements really knows the most about trees.

Town commons.

In the northeastern states nearly every village has its town common, a small central open space usually very attractive. It gives indeed a special character to each town which possesses something of this sort. In mid-western states there are somewhat similar "parks," usually open spaces of one or two square blocks in extent. In the southern and southwestern town there is often a courthouse square having somewhat the same character except that, unfortunately, the main public building is usually placed in its center. All such commons, parks, or squares, however, require pretty much the same horticultural improvement. In general the embellishment most desirable is to be found in fine well-grown trees. These should nearly always be of the same species and of the largest, most vigorous native kinds, rather than of any fussy "ornamental" species. Most public squares or commons are at their best when the horticultural treatment is confined to such large trees and smooth strips of lawn. The use of flower-beds on such grounds is to be generally reprobated. While their exclusion is not an absolute rule, the exceptions are very rare.

Shrubbery borders are sometimes used on these town commons or parks. In special cases they may be justified, but the presumption is against them.

When public buildings are placed on such squares (they should always be placed outside the squares, facing upon them), it is frequently desirable to soften their outlines by foundation plantings. These should be of hardy shrubbery, usually such as has fine texture. Species of weedy growth (such as hazel and *Rosa carolina*) should be avoided. Species of coarse texture may be used with large coarse architecture, especially with heavy rusticated brick or stonework,



LXIII. View in a landscape cemetery.

and in positions where they will always be seen from a considerable distance. Attention should be given to placing on the north side of buildings those species which will thrive in shade, such as barberry, privet, rhododendron. On the south side should be placed plants which will withstand the sun; and perhaps some drought, for example, spireas, coral berry, ceanothus.

The treatment of parks is more fully discussed elsewhere (see *Parks*, page 1801).

School grounds.

School grounds throughout the country are generally neglected. They present a bare, unattractive appearance wholly inappropriate to their use. This condition is widely recognized and nearly every community is anxious to correct it. The problem, however, is difficult.

Generally speaking, large trees are the most useful amelioration for school grounds. These should be placed especially on the south and southwest sides of the school-house in order that the shadows may fall upon the building during school hours. Large-growing native species are particularly desirable, although throughout the northern states the common domestic apple tree seems entirely appropriate, especially for the rearward parts of school lots.

Good lawns are very desirable on school grounds wherever they can be maintained. They are, however, admittedly impossible in many cases.

Border plantings of shrubbery may be attractive, especially at the backs of school grounds, and more especially upon large grounds. Foundation plantings about the building are nearly always desirable when they can be maintained. Other horticultural embellishments such as flower-beds, are to be looked upon with disfavor.

On large school grounds such as every country district ought to have, there should be maintained school-gardens. In addition to the regular school-gardening work, good country schools should undertake to maintain small arboreta of native species. These may also be developed in the form of bird-gardens, adding interest to the gounds and supplying material for constant study.

Grounds designed for play must usually be bare. In some cases turf can be maintained, and is of course, desirable wherever it is possible to have it. Shade trees should be supplied wherever there is room, especially about the margins.

Church grounds.

The church grounds present no such difficulties as are found on the school grounds. They are rarely overrun by crowding multitudes. There is ample opportunity for every sort of horticultural improvement. It is surprising that this opportunity is not more widely acknowledged. The small country church is especially in need of good tree-plantings, but even in villages of considerable size the church grounds are large enough to use a number of large trees. Foundation plantings of shrubbery are effective with a great many church buildings, especially stone buildings of Gothic type with buttresses. The plain wooden churches of the Middle West also need foundation plantings wherever they can be supplied.

It would seem best in connection with many church grounds to develop pleasant outdoor playgrounds, social grounds, or even such places as would be particularly adapted to outdoor meetings. In many parts of the South and West, outdoor evening church services are decidedly popular during the long summer months. But definite and proper provision for them is rarely made.

Cemeteries.

The park cemetery is a distinctly American idea and is of such importance that it is more fully treated in a separate article (see *Cemeteries*, page 1807). At this point we may merely call attention to the squalid unkept rural and village cemeteries, where very simple improvements would be highly valuable. These would consist chiefly of plantings of good trees and shrubs with such turf lawns as could be kept up.

State, county, and national parks.

Another form of the public improvement which is destined to play a conspicuous part in American life in years to come is the larger public park maintained by county, state, or by the nation. These all of course require extensive horticultural development, chiefly in the planting of trees and the maintenance of native shrubs and herbaceous species. The national forests really belong in this class. In them the conservation and exploitation of the tree flora has both an economic and a social value. This general matter, however, is discussed under Parks.

Home grounds.

Most village improvement undertakings make a strong point of the improvement of home grounds. This, however, is based entirely on the public interest, the public in fact, having a very great concern in the attractive appearance and sanitary condition of all home grounds. The horticultural treatment of the home grounds is a subject which has received very general attention in America. The selection of trees, shrubs, and other ornamental materials is naturally controlled chiefly by personal taste of private owners, and it seems impossible here, without going too far afield, to give specific directions on this sort of work. As the problem is approached from the village improvement standpoint, results are frequently aimed at through some form of emulation. Various kinds of public contests are established with prizes for the best-kept front yard, the best-developed back yard, for the best flower-garden, and so on. Where such contests have been wisely planned and tactfully directed, the results have been good. FRANK A. WAUGH.

Landscape extension.

The field of university extension work in landscape gardening, or "landscape extension," is the education of the people of a state from the apathy that tolerates bare home grounds, badly planned cities, and wholesale destruction of native scenery and vegetation. Much work in this direction has been done, and always will be, by private landscape architects, by nurserymen, and by magazines and newspapers, but the best opportunity for educational work of a fundamental nature lies with the state universities and agricultural colleges.

Popular demand for landscape extension.

The most obvious demand for landscape extension is the endless succession of letters asking for help in designing and planting home grounds that are too small to justify employing a private landscape gardener. This need is met, to some extent, by commercial agencies that give "free plans" in order to get profits from the sale of planting materials. Some of the work done in this way is of good grade, but much of it is of a gaudiness and artificiality that represents a natural swing of the pendulum from apathy. The money and time wasted on the gardenesque style of planting has been saved to many individuals by showing them how nations and individuals pass through showy and artificial stages before arriving at the naturalistic. Letters from the people clearly indicate that they wish the guidance of public taste in landscape gardening entrusted to educational rather than commercial agencies.

A second popular demand for landscape extension comes from organizations that ask for help in making comprehensive designs for communities. Such work is even more vital than designing home grounds, because it does not merely consider beauty, but goes deeply into the housing problem and all other factors involving the health and prosperity of every inhabitant. Ordinarily such designs must be made by city planners, but landscape-extension workers can render the state a worthy and invaluable service by helping to educate each community to the city plan as an ideal toward which local forces should work steadily, year after year.

A third popular demand for landscape extension is for technical advice on all public problems involving beauty. Road, bridge, drainage, and other projects often threaten the needless destruction of beauty which it would cost much money and many years to repair. Local protests are entitled to a fair hearing and organizations sometimes ask that expert valuation of the natural beauty involved be presented before courts, and legislative bodies. Organizations interested in conservation are continuously asking for advice on aims and methods, as well as popular lectures. The state legislature is besieged by various bodies with competing propositions for additions to the state park system. A logical outcome of all such unrelated efforts is a survey of each state's resources in natural beauty, showing low-cost lands unsuitable for agriculture, their location, size, character, ownership, salable value, relative importance to the people, dangers threatening valuable scenery and how these dangers can be avoided. Such a survey naturally leads to a comprehensive policy for state-owned reservations, and for some control of the great scenic features of state-wide interest, which, in states having no mountains, hills, or seashore, generally comprise water-courses of all kinds, including drainage-ditches, railroad and traction rights-of-way, and the roads. Some of these problems will be undertaken by private landscape architects through commissions, and some by state landscape architects, permanently employed, like state engineers and architects of state highways, waterways, health, sewers, buildings, and lands. Obviously, such work is related to landscape extension, and such commissions or officers may be located at the university for the same reason that a state often locates there such departments as the natural history, geological, and water surveys, and the like.

The aim of landscape extension is to teach the people the best ways of designing and planting public and private grounds for utility, health and beauty. Landscape extension is the democratic side of an art that has been too aristocratic. It is part of a national desire to popularize all the fine arts, as music and the drama have been brought into the daily life of the masses by means of mechanisms and moving pictures. Such aims can never be realized wholly by professional and commercial agencies since economic necessity often forces them to subordinate public needs to private gain. The people should have a set of representatives who decide every question relating to outdoor efficiency and beauty from the standpoint of the people. In this article all questions are so considered.

The lines of work are too varied to be treated here in detail. Some of the most obvious and popular ones may be named and illustrated in a constructive way under the five headings of individual, rural, town, corporation, and state opportunities.

Individual opportunities.

Designing farms and farmsteads.—Some work has been undertaken in several states in planning whole farms for efficiency, and men are now being trained for this work. Many farmstead plans have been made by students in agricultural colleges, under the direction of an instructor. Mail-order plans are not made by private landscape architects, and farmers, as a rule, will not pay for a visit. The great opportunity of landscape extension is to show the farmers how to make surveys and furnish enough information to enable an expert to design the farm layout with the cost of a visit.

Home grounds in cities.—Technically the design of a small city lot is much the same as that of the farmstead, but with less chance for enframing views, more need of screening unsightly objects, and often a narrower range of materials, owing to smoke, gas, shade, and the like. City people are more eager to spend money on home grounds than country people. After a twenty-minute talk at Peoria, Illinois, 750 out of 2,600 persons signed pledges to do some permanent ornamental planting within a year. Later these persons were asked how they kept their promises. Those who replied had spent about $8,000 in the two years, ending November 25, 1914.

Rural community opportunities.

Community plans.—Small communities can often direct their growth without expensive changes. Good work has been done in Massachusetts in designing rural centers. Facilities for such work will probably be furnished in several states under the Smith-Lever law. The census classifies as "rural" communities having 2,500 inhabitants or less. Some of these communities can afford to employ private city planners. Others may have to be designed by state aid, such as landscape extension can provide. Illinois has a community advisor and a director of community clubs who help local organizations federate toward the permanent improvement of rural communities.

County court-house grounds.—The planting of $10 worth of vines on the walls of a court-house may be the first step toward a county plan, such as that made for Moore County, North Carolina. The farm advisor movement is beginning to bridge the gap between town and country. Trenton County, Missouri, is one of the first to unite all business men (including practically all of the farmers) in a single county improvement organization.

Township parks.—It is now recognized that country people need parks and playgrounds quite as much as city people, and that they are entitled to have something of a higher grade than amusement parks run by commercial interests. Leaverton Park, near Palestine, Illinois, is a high-class farmers' park organized under a little-known law permitting several townships to unite in levying adequate taxes for making and maintaining rural parks.

Town opportunities.

Town planning and planting for efficiency and beauty.—Massachusetts has a law requiring every city of 10,000 inhabitants or more to have a city plan. Such plans should be made by private landscape architects. The function of landscape extension is to promote the ideal of a city plan and to furnish, on request, the names of two or more competent city planners.

School grounds.—It often happens that money can be raised for planting, but not for plans. In such cases landscape extension may furnish designs. Such work is educational to children and townspeople, and the results, though quickly attained, are permanent.

Street trees.—The needless butchery done by wire-using corporations leads to frequent requests for lectures on street trees. Such efforts commonly result in the establishment of a shade-tree commission or city forester, controlling the corporations in harmony with laws like those of New Jersey, Ohio, and Massachusetts, as presented in Solotaroff's "Shade Trees."

Neighborhood planting.—Frequently the greatest improvement that can be made in the shortest time and at the least expense is to plant the front yards of a single street for three to five blocks. Shrubbery for foundations and for connecting the whole street into a park can often be planted at a cost of $15 to $25 for a family. This work is expensive to a state, owing to the large number of persons whose taste must be educated to conform to a plan that will set a higher standard for the community. However, such effort greatly stimulates the planting of home grounds in all parts of a town. There is serious danger of debasing public taste by leaving neighborhood planting to commercial agencies that make no plans and merely plant "best sellers," especially curiosities and other gardenesque materials. Careful plans should be made by state aid in the many cases in which the cost of experts cannot be afforded.

Corporation opportunities.

Railroads.—The first duty of railroads toward public beauty is commonly thought to be the building of good stations and planting of station grounds. The Boston and Albany and the Pennsylvania have already begun to beautify their rights-of-way in a permanent and naturalistic manner. Theoretically, the principles of wild gardening can be applied to rights-of-way so as to save the wild flowers and shrubbery, with little more expense than the cost of mowing everything. It is probable that railroads running through monotonous, level countries, can restore or create a characteristic type of scenery at reasonable expense. Some even think that this can be done in such a way as to increase passenger traffic. The laws which, the railroads assert, compel them to cut down all brush and weeds, have been interpreted by lawyers to refer only to noxious vegetation.

Traction lines.—Interurban lines sometimes ask for advice on the merits of plans submitted for trolley parks. These are generally in the gardenesque style, where naturalistic treatment would be better for the people. At least one line has shown a disposition to get better plans and consider a comprehensive policy for all its parks and station grounds.

State opportunities.

State parks.—Every state needs large reservations of cheap land where the toiling millions may restore the energies necessary to do the world's work. Wisconsin and other states have reservations where laboring people who have only two weeks' vacation may camp amid wild surroundings. Every type of natural scenery should be represented, for scientific and educational purposes.

Waterways and drainage.—Great public improvements, like flood prevention and reclamation projects, are commonly conducted without regard to the rights of beauty. Competent landscape architects should be employed in all large engineering works affecting the face of nature. Water-courses are commonly treated as sewers and otherwise defaced. Landscape extension can arouse each local community to do its share toward restoring beauty to the watercourses.

Roadside planting.—Every state and county can have a great rural park system without the cost of buying land, by saving or restoring to the roadside the native trees, shrubs and flowers. The famous drives connecting Madison, Wisconsin, with the surrounding lakes, afford a good example. The comprehensive plan now being made for the Lincoln Highway, contemplates a consistent scheme of roadside planting from the Atlantic to the Pacific. Several miles of planting have lately been done near Monticello, Sidell, and Barrington, Illinois. The cost of restoration varies from $500 to $1,500 a mile, or about 10 per cent of the cost of constructing concrete roads.

State character.—One of the greatest opportunities of landscape extension is to show how every home and town may connect with a large scheme to give the whole state a characteristic beauty. The Middle West had developed a prairie style of landscape gardening based upon conservation and restoration of native beauty and repetition of the horizontal line of prairie land or sky, by means of trees and shrubs with horizontal branches or flower clusters. One designer has submitted an itemized list of $6,000,000 worth of work accomplished from his plans in the prairie style since 1901. Each state may have something like the "Illinois way of planting," which is the use of a high percentage of permanent materials native to the state.

Methods of landscape extension.

All activities of landscape extension except administrative, can be summarized under the heads of lectures, publications, and design.

Lectures.—These are necessarily illustrated, and high-grade colored lantern-slides are much more effective than plain ones. Before-and-after pictures showing money spent in the state on permanent native planting are more convincing than random, theoretical, temporary, or foreign subjects. Apathy may be indicated by those who stay away, but those who attend the lectures are generally enthusiastic to the point of making pledges, and of asking for more state aid in design than it is proper to grant. Mere enthusiasm for wholesale public planting often leads to poor arrangement, unfit material, and neglect of cultivation. Carefully organized campaigns give better results than individual lectures. Traveling expenses are paid by local communities.

Publications.—The traditional type is the practical circular, which is essential, but presupposes general interest in planting. The inspirational type is exemplified in a type or form of publication that contains many illustrations, for the reason that landscape gardening must be taught chiefly by means of pictures. Since truth in landscape gardening is not exact but comparative, the pictures may well be arranged in contrasting pairs.

Design.—In rich, old communities the people are not apathetic, but willing to improve if someone will show them what to do. Therefore, after every lecture, each community is likely to ask for a well-designed demonstration. In the West, many communities have no example at all of landscape gardening, or a poor and antiquated one. They will wait indefinitely unless the state supplies a standard. Such designs have been supplied on conditions about as follows:

1. The project must be educational. Therefore, it should not compete with landscape gardeners, and it should be the smallest unit that will stimulate a large amount of designing and planting.
2. It should be for public, not private, benefit. Therefore, front yards may be designed in street plans, but not back yards, except for corner and vacant lots where screening of unsightly objects may be necessary.
3. A reasonable guarantee must be furnished before the plan is made, that a definite sum of money will be spent, if the plans are acceptable, and adequate provision must be made for maintenance.

Some results of landscape extension.

At the end of its second year, the Division of Landscape Extension at the University of Illinois had 5,200 pledges "to do some permanent ornamental planting within a year." The signers were then asked to tell how they had kept their promises. The number who replied were 991, or 19 per cent of the signers. Of these, 206 spent nothing, while 785 spent a total of $75,117 (not including labor), the average being nearly $76. The mean expenditure of those who spent over $100, was $392. This class is composed of persons who can afford the services of a landscape gardener. The mean expenditure of those who spent less than $100 was $22. This represents the general public which commonly thinks that it cannot afford the services of a landscape gardener. The average expenditure ($22) is about five times as high as expected. Not all of this planting was due to the influence of landscape extension, for many persons had determined to plant something before they heard a lecture or read a circular. In such cases, the extension service often influenced the people to choose more appropriate plants and arrange them in better ways than they could have done without state aid or with commercial aid.

Relation to private landscape gardeners.

Obviously, landscape extension should develop in harmony with the principles laid down by the American Society of Landscape Architects for the elevation of the profession. It is a general policy for universities to show no favoritism and therefore always to suggest two or more men competent to do any particular piece of work.

Relation to nurserymen.

Landscape extension should be in sympathy with the ideals of the American Nurserymen's Association, so far as they agree with educational and professional standards. Incidentally, the propaganda creates much business for nurserymen, but its prime purpose is education. Therefore, when persons submit plans in the gardenesque style made by nurserymen, and ask for criticism, landscape extension workers should inform both parties simultaneously that the naturalistic style is considered superior to the gardenesque by the profession, and should furnish, on request, a list of landscape gardeners practising in the state. When prices are habitually excessive, the nurserymen, at least, should be informed. A university cannot recklessly promote mere quantity in planting; it must stand for quality and fair play. Landscape extension generally deals only with permanent materials, leaving to other agencies the promotion of temporary plantings, as well as fruits and vegetable-gardens.

Historical note.

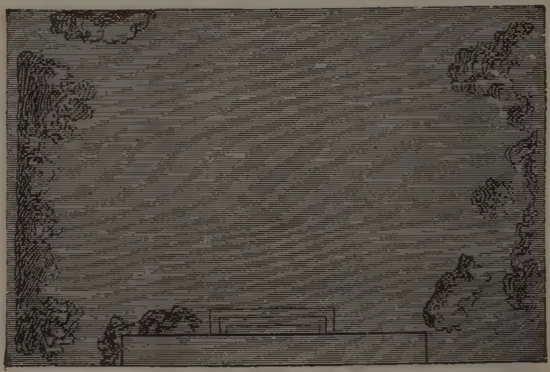
The phrase "landscape extension" was used officially in February, 1914, at the University of Illinois. Prior to that, university extension work in landscape gardening had been undertaken in several states, notably in Massachusetts, but incidentally to regular teaching. The first state to employ a man to give his entire time to landscape extension was Illinois, where the work was begun in October, 1913. It is organized under the Department of Horticulture. Since then full-time workers have been engaged in Massachusetts, Iowa, New York and elsewhere.

WILHELM MILLER.

Lawns and lawn-making in landscape planting.

For most persons the word lawn bears a vague meaning, compounded of their recollection of grass-covered spaces dotted over with trees and shrubs, and of broad areas covered simply with closely mown turf. Both are correct impressions: but the more important feature is that a lawn shall be an open area of grass space (Figs. 2104, 2105). Many exceptions or additions to this definition may, however, be admitted. A great white oak, for example, rugged and picturesque against the evening sky, needs only to be seen to furnish an ample excuse for its retention on any lawn. But this would be a happy chance, not affecting the principles which should govern the construction of a lawn on an open area.

It may readily appear that the lawn will, as originally designed, prove too sunny or too strongly wind-swept over its extended expanse; but the remedy for this will be found to lie not so much in planting single trees or detached groups of trees over the uncovered area, as in extending limbs, points, promontories and peninsulas of trees or trees and shrubs directly out from the main body of bordering plantations which will usually frame the lawn and the different pictures that will appear in any properly unified scheme of landscape gardening. The art of the designer will display itself in determining the relative sizes of the lawns and these inclosing or framing plantations. A careful eye must, of course, be given to the individuality of the lawn itself, which should never be allowed to run over into the neighboring plantations. A like principle applies to all kinds of art—it is fundamental and vital in its character. The reader may fancy that its application would tend to limit the beauty of landscape gardening by eliminating certain features of natural beauty, such as trees, shrubs, and beds of flowers, but if he will look at an open lawn with discerning and sympathetic eyes, he will find that the "moving cloud-shadows, waving grass, rich patches of dark and light green, studded with the starry radiance of the humble flora of the grass, and the hundred incidents of blazing or subdued color and form that appear on the surface of an open meadow," need no added beauty of tree or shrub to perfect their nearly unapproachable loveliness. So important does the writer consider the essential and peculiar beauty of the lawn as distinguished from that of any other part of the home domain, that he always feels inclined to term it the true focus of the picture, the central point of interest in any landscape gardening design.



2104. Ground-plan of a nature-looking grass space, showing relative importance of lawn and planting

This being the case, it behooves us always literally to leave no stone unturned or clod of earth untilled and unfertilized in order to secure a satisfactory open lawn. Did the reader ever see such an one? Let him answer frankly to himself whether he has or has not seen a lawn which showed no traces of quick-grass and other early weeds in July, nor any summer grass and later weeds in August and September,—above all, a lawn which would stand a protracted drought without artificial watering. Very likely he will think it is impossible to make such a lawn under the conditions of soil and climate which each and all of us are apt to believe specially characteristic of the spot of ground on which we live. Perhaps, on the other hand, he will declare that he has seen such a lawn in some remote place, but if we question him, ten chances to one we shall find that his observation of this exceptional lawn is limited—that he has not wintered and summered near it, or seen it during its periods of "storm and stress." The writer knows one place where such a lawn can be seen, and he refers to it, not because it is properly a lawn, for it lacks the requisite framing plantations; but it is perfect in the first essential of a good lawn—it is a piece of perfect lawn grass. A brief description will show how this standard of excellence was reached. The lawn consists of small patches of grass turf on a private farm in Manchester, Connecticut. Each patch was worked and turned over with various ingeniously contrived hoes, forks and rakes until the last lurking weed was removed that could be found by dint of skill and untiring patience. The soil was that of an old garden, and naturally good. It was tilled in the most thorough manner and not fertilized at all, for fear new weeds be introduced. Then, in this mellow and receptive medium, were set cuttings or joints of the hardiest and most luxuriant varieties of grasses which had been discovered by months and even years of keen and intelligent search in the old meadows of both the Old and the New World from Austria to Australia. The result is an elastic firmness, an endurance, depth and richness of the turf which suggests to the tread the deep pile of some Eastern carpet woven in a hand-loom.

But all can not attain this standard on their lawns. For those who do not look higher than the ordinary standard—and even this is none too often desired, or even understood, by the general public—the following directions for lawn-making may be given:

1. The lawn should be carefully graded, either convex, level or concave, in such comparatively long, suave and graceful lines as will accord with the peculiar conformation of the ground (Fig. 2106).

2. Plow, harrow or spade, and fork the soil of the lawn to a depth of 2 feet, if possible, and keep removing the stones and burning the gathered rubbish for several weeks, or as long as you can persuade yourself to do it, or pay anyone else to do it; with the full assurance that no matter how much you do, you will not be likely to destroy all the weeds and win the very best possible results.

3. Enrich the soil by a covering of still richer mold. Next to this in efficiency are bone-dust, lime, superphosphate, nitrate of soda, and nitrogenous manures like ground flesh and bone mixed in proportions suited to the special soil, which may vary materially in a distance of a few hundred yards. The usual proportions are one ton to the acre of ordinary artificial fertilizers, such as superphosphate of lime and bone-dust, or fifteen to twenty-five of well-rotted stable-manure. If artificial fertilizers are not available, then take cow-manure, sheep-manure, or last of all, because it is the most productive of weeds, ordinary stable-manure. These natural manures are, after all, the best, save for their weed-bearing qualities. They will need composting with several times their bulk of good soil and even spreading and harrowing or raking in throughout the surface of the lawn.

4. For turfing, the cleanest grass seed that can be obtained at any price will be found the best in the end. The bulk of this seed should be Kentucky blue-grass or June-grass (*Poa pratensis*) mixed with red-top or herd's-grass (*Agrostis alba* var. *vulgaris*), or *Agrostis canina*, the Rhode Island bent-grass. The advantage of using several kinds of grass is that the first-comers hold possession of the ground against incursions of weeds until the stronger but slower-growing Kentucky blue-grass gets complete roothold, when, in the struggle for life, the earlier growths of grass, being weaker, go to the wall and are crowded out of existence. How fine this blue-grass may become under favorable conditions it will be needless to point out to those who have seen the grass meadows of Kentucky.

2105. An open area of grass space.

5. On a calm day the seed should be sown evenly over the lawn surface—a task which can be well done only by much skill and experience. The ground will then need careful raking with a fine-toothed iron rake, and rolling with an iron roller, the heavier the better. In very dry weather or very windy weather it is hardly worth while to sow grass seed.

6. As soon as the grass has grown 3 or 4 inches, cut it first with a scythe and afterward with the lawn-mower, in order to secure a good thick-set turf. Every spring, and oftener if wet weather prevails, a compacting with the iron roller will serve a good purpose. Fertilizing on the top of the lawn in the winter is always in order, provided the remainders of rubbish from the stable-manure that may be used be removed early in spring before the grass starts.

7. The last and perhaps the most important care to be given the lawn in the process of its establishment is the weeding of the first summer. The next is the weeding of the second summer—and the third is the weeding at any time it may need it, no matter how many years may have elapsed since its construction. The onion-patch and the flower-garden need no more weeding than the lawn, if for no other reason than because the use and beauty of either onion-patch or flower-garden can never, combined, equal those of the home lawn. In it, skill and patience and the love of beauty find abundant reward.

Samuel Parsons.

Lawns for the South.

For many years handsome lawns in the South were a rarity, and it was the impression, generally, that good lawns were not possible in that region. Unfortunately, many kinds of grasses not suited to certain sections of the South were sown. Being unadapted to the soil and climate, consequently failure followed.

By careful and judicious selection of the hardier varieties of grasses, and a proper and careful blending of them, beautiful lawns are now possible in almost every part of the South, but, to be successful, the soil must be properly prepared and fertilized. Most of the southern soils contain an excess of acidity, and, therefore, this must be corrected by an application of lime. This should be used at the rate of 1,000 to 3,000 pounds to the acre, and should be evenly distributed over the area to be treated. Soils lacking in humus should have this deficiency supplied by the following treatment: Cowpeas, soy-beans and velvet beans should be sown in the spring, and crimson clover in the fall, and when matured, cut and allowed to lie upon the ground for a few days, then chopped up fine with a cutaway harrow, and properly turned under, so that none of the stems and roots remains on the surface. Apply a good high-grade fertilizer, bone-meal, sterilized sheep-manure, or a material containing a high percentage of phosphoric acid, nitrogen and potash. Apply at the rate of 500 to 800 pounds to the acre. This should be thoroughly incorporated with the soil. In the spring, previous to preparing a lawn for fall seeding, thoroughly rotted barnyard manure can be used. The only objection to barnyard manure is the risk of bringing foreign weeds and grass seeds into the lawn. Before putting in the seed, the ground must be very carefully graded and raked smooth. Seeding should be done at the rate of fifty to one hundred pounds to the acre, according to the varieties used. Rake in the seed lightly and then roll. Never attempt to sow grass seed on a windy day. In the spring a top-dressing of bone-meal should be applied.

Mow the lawn regularly. Water when needed, but apply so it will fall lightly on the ground. Many lawns are ruined by applying the water with too great force.

2106. An easy grade for a lawn.

For the extreme South, Bermuda-grass (*Cynodon Dactylon*), St. Augustine-, Charleston-, or goose-grass (*Stenotaphrum secundatum*) are the best. About Miami, Fla., a fine-leaved form of Korean lawn grass, *Osterdamia matrella* (*Zoysia tenuifolia*) is very successful, withstanding drought well. The Bermuda is a plant of trailing and stoloniferous habit. It is a native of India. It is widely disseminated throughout the South and is a most valuable and reliable grass for pasture. Unfortunately, with the first approach of frost it turns brown and does not present an attractive appearance during winter.

When it is not desired to tear up a Bermuda lawn, it can be given a bright and cheerful aspect during winter by first cutting the Bermuda-grass very close, then scarifying same with a rake or small cutaway harrow, the blades set straight so as not to turn up the lawn, applying a liberal amount of bone-meal and sowing a good lawn grass adapted to the locality. Rake this in and roll.

A Bermuda-grass lawn can be made by cutting the roots in short lengths, chopping with a hatchet, or passing roots through a feed-cutter, and sowing the roots broadcast, and plowing in lightly; or the uncut roots may be planted in furrows, same covered to a depth of 4 inches, the ground then leveled and rolled. The roots may be planted in autumn, or from February until May, but, when they are planted late, care must be taken that the roots are not exposed to the sun so as to dry out. The Bermuda-grass will give excellent results if kept well enriched and frequently mowed. It adapts itself to almost any soil, except that which is extremely wet.

The St. Augustine-grass is an early-growing perennial plant, with flat or channelled leaves. It is found naturally in the pine-barren swamps and ponds from Florida to North Carolina, and it is well adapted to the sandy soil of the coast, even those which are commonly termed "salt-water lands." It is, therefore, of unquestionable value for such localities. This grass is grown from rootlets, planted in rows a few inches apart, but, to get the best results, the soil must be well prepared and fertilized. It requires frequent applications of the lawn-mower. It is a coarse grass, but has a good color and adapts itself to soils where few other grasses are possible.

Joint-grass (*Paspalum distichum*) is a native of the South and is usually found in moist or low grounds. It can be utilized in soils that are too wet to suit Bermuda, but, at best, makes an indifferent lawn, as it is of low creeping and not sufficiently dense habit.

For the middle sections of the South, some good mixtures of the different hardier grasses, thoroughly tested, have been made, and when the ground has received the proper preparation, satisfactory results have been attained.

For the upper or mountainous sections of the South, blue-grass and many of the mixtures of the hardier grasses are very successful. L. A. Berckmans.

LÁNSIUM (from the Malayan name *lansa* or *lanseh*). *Meliàceæ.* A small group of oriental trees, of which one species is cultivated for its edible fruits.

The genus is allied to the umbrella tree (Melia) grown in the S. U. S., and the tropical mahogany (Swietenia). Lvs. imparipinnate: fls. produced in axillary panicles; sepals 5, petals 5, the 10 stamens formed into a tube: fr. a berry, 5-celled, each cell containing 1 or 2 seeds.—Species about 4, in India and Malaya.

doméstieum, Jack. Langsat. Lansa. Lanseh. Lanzon. Ayer Ayer. A medium-sized, rather slender tree, native of the Malayan Archipelago: lvs. with 3 or more pairs of elliptical to obovate, alternate, shortly petiolulate lfts., about 4–6 in. long and 2–3 in. broad: fr. globose or ovate, 1–1½ in. long, calyx persistent, the sepals small, dry, brownish; seeds 1 or 2 developed, remainder usually aborted, of variable size, oval; testa membranous.—The langsat is frequently seen in the markets of Manila, Canton, Singapore, Penang, and other cities in that part of the world. The round to oval frs. are borne in clusters, and are not unlike loquats in general appearance, except that the color is a dull straw or brownish yellow, and the thick leathery skin, which does not adhere to the flesh, is pubescent on the surface. The flesh separates into 5 or less distinct segms. like those of an orange, and is white, translucent, very juicy, and of a subacid pungent flavor, sometimes tasting slightly of turpentine, especially if the thin membrane which surrounds the segms. gets into the mouth. It is eaten fresh or prepared in various ways. Ward wrote that the langsat "is by many reckoned the finest fruit in the peninsula. The month of July is the season at Malacca when it is had in the greatest perfection." Its season extends to Sept. A variety known as "duku" or "doekoe" is larger than the type, and considered much the better of the two. Both the duku and the langsat are commonly planted in gardens, and spring up along the roadsides. They have recently been planted in S. Fla. and the W. Indies. The duku is produced in smaller clusters than the langsat, and is spherical in form, varying from 1–2 in. diam. The skin is about ⅛in. thick, leathery, dull brownish yellow in color, covered with a thick grayish pubescence. The flavor is very pleasant and refreshing, scarcely comparable to that of any temperate fr. The seeds retain their vitality for some time, if not allowed to become too dry, and germinate readily when planted in light, loamy soil. Seed prop. is the only method known to be employed in Malaya. F. W. Popenoe.

LANTÀNA (old name, once applied to a viburnum). *Verbenàceæ.* Mostly shrubs or undershrubs, sometimes half-climbing, with opposite or verticillate rough dentate leaves, and spikes or cymes of small verbena-like flowers; one species or group much grown by florists, and a few others sometimes planted.

Plant scabrous, hirsute or pubescent: fls. small, red, orange, white or otherwise, in dense spikes or heads, gamopetalous, the calyx very small, the corolla somewhat irregularly 4–5-parted but not bilabiate, the corolla-tube slender; stamens 4, didynamous, attached midway in the tube, included; ovary 2-loculed, becoming a fleshy or dryish drupe with 2 nutlets: bracts subtending the head often imitate an involucre. Verbena differs in having achene-like nutlets and long-tubular 5-

toothed calyx.—Species probably 50, mostly in Trop. and Subtrop. Amer., but also in the Old World. Lantanas have been long in cult., and it is difficult to refer the garden forms to botanical species. The species themselves are confusing. Most of the garden kinds are of the *L. Camara* type. There are several camara-like species which probably have hybridized to produce these forms; but Voss regards these species as only forms of *L. Camara* (preferring, however, to use the name *L. aculeata*). Accepting *L. Camara* in Voss's sense, the garden lantanas may be said to be derived from that species; and this view is adopted below. In recent years, a strain of very dwarf varieties has become popular as border plants. The lantanas are free-flowering in winter and summer, but an odor of foliage and flowers that is disagreeable to many persons prevents them from popular use as cut-flowers. They are very useful in window-gardens and the dwarf kinds make good subjects for hanging-baskets. From the window they may be transferred to the open in summer, where they bloom profusely.

The culture of the florists' lantana is relatively simple. It is grown under glass for bloom in cold weather and also in the open in summer. It has been improved in its usefulness as a bedding-plant of late years, largely through the efforts of French hybridists. The older varieties were mostly rather tall and lanky, later in coming into bloom, and dropped their flowers badly after rain-storms, but were showy in warm and dry weather. The new varieties are dwarf, spreading and bushy in habit, early and free-flowering, and the heads or umbels of bloom average much larger, with florets in proportion; nor do they drop from the plants as did the old varieties in bad weather. These newer kinds are not so well known as they should be. They are very desirable for any situation where sun-loving bedding plants are used, in groups or borders, window-boxes, baskets and vases.—The lantana is not particular as to soil, provided the exposure is sunny, and also that the soil is well supplied with moisture at least until a fair growth has been made. When well established the plants do not seem to mind drought, and continue bright and attractive in the hottest weather. They should not be transplanted out in the open before danger of frost is over. If the old plants are wanted for propagation, cut them back and transfer to pots early in September, and when they start into new growth the soft wood will furnish cuttings that root easily. Keep young stock in a warm position through the winter months, and repot in April.—Save the old plants, after frost has nipped their freshness late in autumn, prune severely back, remove them indoors, giving them a temperature anywhere above 40°, and with a little attention and fresh soil, every plant will be a perfect specimen, covered with blooms in May. Gardeners train them into fine standards, as prim and shapely as need be. Among the French varieties are very dwarf spreading growers, about 8 inches high. (Grove P. Rawson.)

A. *Plant mostly spiny (at least when wild): fr. juicy.*

Càmara, Linn. (*L. aculeàta,* Linn.). Fig. 2107. Small shrub, 1–4 ft. high, hairy, sometimes with short hooked prickles: lvs. rather thick, rugose, scabrous above but pubescent beneath, ovate or cordate-ovate, mostly short-acuminate, crenate-dentate, the petioles short: clusters of fls. on strong axillary peduncles which may or may not exceed the lvs.; fls. in a dense, nearly flat-topped head, usually opening yellow or pink but changing to orange or scarlet, the bracts narrow and not conspicuous. Trop. Amer., extending north to Texas and S. Ga. B.M. 96. L.B.C. 12:1171 (as *L. scabrida,* Ait.).—In the wild, the plant may grow 10 ft. high, and it is usually prickly (hence the name *L. aculeata* of Linnæus). The cult. plant is less prickly or even unarmed. Color of fls. varies on different plants, and there are many named forms. This group is now a prominent plant in many tropics. It is possible that more than one species is involved in the following forms. *L. hýbrida* is a name for the dwarf garden forms. *L. Píctavi* is a hybrid between *L. Sellowiana* and a garden form.

Var. **nívea,** Bailey (*L. nívea,* Vent.). Fls. white, the outer ones becoming bluish; heads rounder. B.M. 1946.

Var. **mutábilis,** Bailey (*L. nívea* var. *mutábilis,* Hook.). Remarkable for the change of color in the nearly globular heads: in little more than a day, the fls. may change from white through yellowish, lilac, rose and blue. The outer fls. open white and run through yellowish, rose and lilac; the inner ones open yellowish. B.M. 3110. R.H. 1852:461.

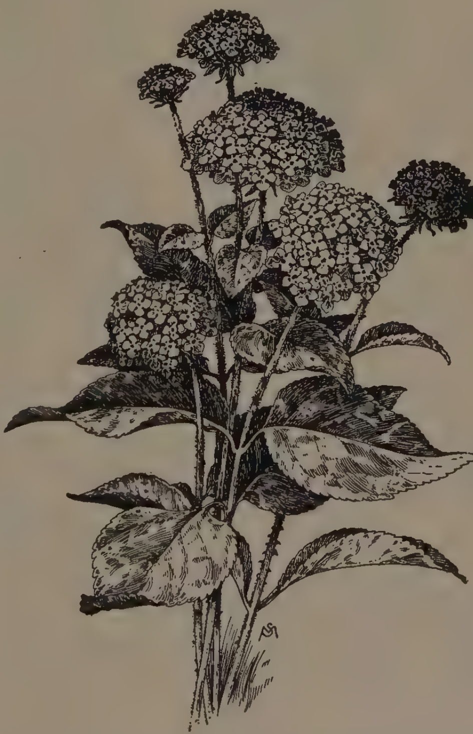
Var. **místa,** Bailey (*L. místa,* Linn. Not spelled *mixta* by Linnæus, although it is so spelled by later authors). Outer fls. opening yellowish and becoming saffron and brick-red; inner fls. yellow, changing to orange. Said to be distinguished by numerous recurved prickles on the branches.

Var. **cròcea,** Bailey (*L. cròcea,* Jacq.). Fls. opening sulfur-yellow and changing to saffron. R.H. 1852:461.

Var. **sanguínea,** Bailey (*L. sanguínea,* Medikus). Fls. opening saffron-yellow, changing to bright red.

AA. *Plant not spiny: fr. either juicy or thin-fleshed.*

lilácina, Desf. Particularly recommendable in S. Calif. for its upright panicles of rosy lilac shining berries, which persist through the winter: erect, with spreading 4-angled hirsute branches: lvs. opposite, ovate to oblong or lanceolate-triangular-acute, the base rounded or slightly cordate, crenate, hairy-scabrous above and velutinous beneath: fls. rose-lilac with yellow throat: berry succulent. Brazil.—The *L. purpurea* of Cyclo. Amer. Hort., 1900.

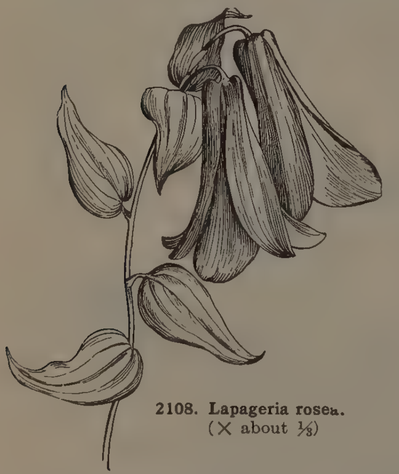


2107. Lantana Camara. (×½)

salvifòlia, Jacq. (*L. salviæfòlia,* Mey.). Erect, much branched, aromatic, unarmed, 3–6 ft., pubescent on young parts: lvs. opposite or in 3's or 4's, short-petiolate, oblong-ovate, rounded or subcordate at base, obtuse or somewhat acute, crenate-serrate, pubescent, punctate-glandular: fls. lilac or pink in a subglobose or cylindric peduncled axillary spike; calyx tubular, not ribbed, but more or less distinctly 4-nerved, obscurely 2-lobed or 4-toothed; corolla-tube straight, slightly dilated about the middle, pubescent above on outside but glabrous within, ¼–½ in. long: fr. a purple subglobose drupe with sweet edible pulp, used for food in Zululand in times of scarcity. Trop. and S. Afr. *L. salviæfolia*, Hort.(?).

trifòlia, Linn. (*L. ánnua,* Linn.). Half-shrubby, hairy: lvs. ovate-lanceolate or elliptic-oblong, pointed, crenate-dentate, in 3's or 4's: heads becoming ovoid or oblong, the involucre not conspicuous; fls. rose-lilac varying to white, with yellow throat: fr. rather pulpy, showing well amongst the bracts. Trop. Amer. B.M. 1449.—The name *L. annua* seems to have been applied to young plants, on the impression that they were annuals. The picture of *L. annua* in B.M. 1022 is quite as likely to be a form of *L. Camara.* Little known in cult.

Sellowiàna, Link and Otto (*L. delicatíssima,* Hort.?). WEEPING OR TRAILING LANTANA. Twiggy, slender plant with lopping or trailing pubescent branches: lvs. small, ovate, tapering below, close-toothed: fls. small, in long-stalked small heads, rosy lilac, the outer bracts or scales of the involucre broad-ovate and hairy and half or less as long as the slender pubescent corolla-tube. S. Amer. B.M. 2981. B. 3: 115. R.H. 1852: 461 (?).—A very profuse bloomer in both winter and summer, and most desirable for pot or basket cult. Should be better known. Verbena-like. The plant seems to be an escape in Fla.



2108. Lapageria rosea. (× about ⅛)

involucràta, Linn. Low, much-branched bush, with obscurely 4-angled gray branches, and blunt, ovate, small, crenate-dentate lvs.: fls. small, nearly or quite equaled by the ovate involucre-bracts. Trop. Amer., reaching north to S. Fla. and S. Texas.—Said to be occasionally cult. indoors for the light lilac or white fls.

L. H. B.

LAPAGÈRIA (from a personal name, probably for the Empress Josephine, *née* Tascher de La Pagerie). *Liliàceæ.* CHILEAN BELLFLOWER. A single species, a noble, half-hardy evergreen twiner, allied to the smilaxes, considered to be one of the choicest subjects to grow under glass.

Leaves alternate, lance-ovate or cordate-lanceolate, 3–5-nerved, acuminate: fls. large and showy, bell-shaped, hanging singly from the upper axils or somewhat racemose at the end of the vine, about 3 in. long; stamens 6, borne on the torus or slightly attached to the base of the inner segms., shorter than the perianth; ovary sessile and 1-loculed, with 3 parietal placentæ, ripening into a 3-angled, oblong, fleshy, indehiscent, berry-like beaked fr. and bearing nearly globular seeds imbedded in the pulp. **L. ròsea,** Ruiz & Pav., is the only species. Fig. 2108. It has rose-colored or rose-crimson fls., with lighter spots. Chile. B.M. 4447. F.S. 5:491; 20:2059–2060. R.H. 1850:101. Gt. 47, p. 101. G.C. III. 20:657 (frs.); 25:45. Gn. 34, p. 321; 48, p. 475; 49:174; 55, p. 57. G. 1:557; 18:626; 34:753. G.W. 14, p. 328. H.F. II. 6:40. Gng. 5:356. Mn. 7:191.—The species is variable in vigor, floriferousness, size, color and substance of bloom, and there are a number of named horticultural subvarieties. Var. **albiflòra,** Hook. (var. *álba,* Hort.), has white or whitish fls. B.M. 4892. R.H. 1852:441. F.S. 20:2059–2060. Gn. 41, p. 53; 49:174 and p. 175; 54, p. 277. J.H. III. 61:349. G.W. 10, p. 8. G. 2:387; 5:409; 17:271; 32:335. F.S.R. 2, p. 221. A.G. 13:745. Gng. 2:187; 5:356. Var. **supérba,** Hort. Fls. large, brilliant rich crimson. Var. **Ílsemannii,** Hort. Fls. larger and more brightly colored than those of the type itself: vigorous and free-flowering. Gt. 46:1445. Var. **Bénsonii,** Hort. Fls. of lighter tint than those of type, especially in interior of the perianth. Var. **gattoniénsis,** Hort. Much like the type. A double-fld. form of the white variety is shown in G. C. II. 17:777.

Lapagerias are tall-twining plants, suitable for rafters or walls in coolhouses, or for culture in the open in the milder parts of the country. They are commonly propagated by cuttings and layers, but strong plants may be secured from seeds, although varieties may not come true. The first live plants were introduced into England in 1847. Lapagerias should be seen more frequently in America. They are considered to be not easy to grow, and a good display is usually regarded as an evidence of skill. Franceschi says that in California the plant prefers shady places "where the atmosphere will never become too dry."

Lapageria rosea and *Philesia buxifolia* have been hybridized by Veitch, producing a plant known as *Philageria Veitchii,* Mast. (G.C. 1872:358). Philesia afforded the pollen. It is not in the American trade, but is a most interesting hybrid. For an anatomical study of it, bearing on problems of hybridity, see J. M. Macfarlane, Trans. Roy. Soc. Edinburgh, 37, pt. 1, p. 207 (1892).

L. H. B.

Lapageria rosea and var. *albiflora* should occupy a position in all cool greenhouse collections. We have no cool greenhouse twining plants that can be compared with them. They can be grown in large pots, trained on a trellis as specimen plants, or if for cut-flowers, they may be planted out on a bench or in a border. Strict attention must be paid to drainage, and the soil must not get into a "sour" condition.—Layering is the best way to propagate lapagerias. When a shoot gets somewhat bare of foliage, it may be twisted backward and forward in a box near where the plant is growing. The box should be filled first, with sand and fine peat, in equal proportion, to the depth of about 3 inches. Peg the shoot to keep it in position and cover with some of the compost. If there are leaves on the shoot, cover them only about one-third. Keep the soil moderately moist; and in time growths will start from the joints, which after a while will throw out roots, and when a sufficient number are formed to support the plants, separate them from the stem and place them in pots large enough to receive the roots without breaking them. The potting material should be one part fiber of loam, out of which all the fine loam has been shaken, one part osmunda fern root (osmundine), one part charcoal, and one part sharp sand. Water carefully until they get a good hold on the compost, after which they may be kept moderately moist.—Lapagerias require to be at all times shaded from the sun, and kept in as cool a temperature as possible. A north house, from which the frost is kept, is an ideal position. If the plants are to be grown in pots, they must be shifted into larger pots before they get too well rooted. This will encourage strong breaks to start from the bottom. These shoots, as soon as they emerge from the soil, should have a piece of cotton-wool twisted around them, for if there are any snails nearby, they will be sure to eat the tender tops, which will ruin the plants. A few stakes should be placed around the pot, to which to tie the shoots, until such time as the plants are big enough to train on the permanent trellis. Be sure to tie them in a regular way, as they will be easier untwisted when the time arrives for their removal.—If lapagerias are intended to be planted on a bench or in a border, they should be well established in pots first. Do not fill all the bench or border at once; it is better to supply only enough material to last for one season, adding a little each year as they require it. The compost should be same as advised for potting, and it should be in rather a lumpy state, as lapagerias do not thrive in any soil of an adhesive nature. The bench or border should be well drained, so that the water may pass through freely, copious supplies being necessary when they are in active growth. After they are well established, treat with manure-water as advised for ixoras. Insect pests may be destroyed by fumigating with hydrocyanic gas in cool weather, and a free use of the syringe at all times. (George F. Stewart.)

LAPEYROÙSIA (Jean François Galoup de Lapeyrouse, distinguished French naval officer, born 1741). *Iridàceæ.* African bulbs, something like freesias, but with mostly blue or red flowers, produced in summer instead of spring.

Corm with matted tunics or coverings, flattened at the base: lvs. usually only 1 or 2 to each st. (sometimes several), very narrow, in some cases nearly terete, distichous: peduncle mostly branched; fls. small, red to white and yellow; perianth-tube subcylindrical, long or short, somewhat dilated upward; segms. nearly equal, spreading, oblong-lanceolate; stamens inserted in the throat; ovary 3-celled: fr. a small caps., oblong or globose, loculicidal.—Species about 50 in Trop. and S. Afr. By dealers they may be listed under the name of Anomatheca, which Baker has reduced to one of the 3 subgenera of Lapeyrousia, characterized by having several lvs. forming a 2-ranked basal rosette, accompanied by a long, branched st. Lapeyrousia is further distinguished from Freesia by having a more slender perianth-tube, with the stamens inserted at the throat instead of below; also by the ovules being more regularly superposed instead of crowded together. The species of Lapeyrousia have an egg-shaped or globose corm about ½in. thick, and matted with tunics: lvs. linear or sword-shaped: infl. various, often a loose, 1-sided, more or less zigzag spike, as in Freesia; fls. variously colored, 1–2 in. across; perianth-tube long or short; segms. spreading, 3 larger than the other 3.

Some of the lapeyrousias can be grown outdoors in the North with some winter covering, and are said to be quite hardy south of Washington, D. C., if planted deep. These plants will probably never have anything like the degree of popularity enjoyed by freesias, because of their later season of bloom and lack of fragrance. Probably the most popular kind is *L. cruenta,* which grows 6 to 10 inches high, blooming in summer and fall. In a sheltered place and in light, porous soil it generally succeeds in the North without any protection, but the bulbs are safer in very severe winters under a covering of litter or straw. The bulbs increase rapidly, and should be divided every few years before they become too crowded.

A. *Color of fls. chiefly blue or violet.*

corymbòsa, Ker. (*Ixia corymbòsa,* Linn. *Anomathèca corymbòsa,* Hort.). This belongs to the subgenus Ovieda, having usually 1–2 basal lvs., while the next 3 species belong to the subgenus Anomatheca, having more numerous lvs. *L. corymbosa* has 1 basal lf. which is spreading, sword-shaped, 4–6 in. long: infl. a dense flat-topped cluster of as many as 15 fls., each about 1 in. across, with practically regular segms., blue, with a star-shaped white figure near the throat, outlined in black after the fashion of Quedlinburg phlox. S. Afr. B.M. 595. J.H. III. 32:379.

AA. *Color of fls. red, with 3 darker spots at the base of the 3 smaller segms.*

B. *Size of fls. 2 in. across.*

grandiflòra, Baker (*Anomathèca grandiflòra,* Baker). Lvs. 1 ft. or more long: fls. bright red; stamens as long as the segms.; the 3 style-branches each 2-cut. Zambesi S. B.M. 6924.—A newer species than *L. cruenta,* and perhaps destined to greater favor. Corm globose (ovoid in the others here described).

BB. *Size of fls. 1 in. across.*

cruénta, Benth. (*Anomathèca cruénta,* Lindl.). Lvs. ½–1 ft. long: segms. bright carmine; stamens less than half as long as the segms.; the 3 style-branches uncut. Transvaal, south. B.R. 1369. L.B.C. 19:1857. P.M. 1:103. J.H. III. 31:397.

júncea, Pourr. (*Anomathèca júncea,* Ker.). Lvs. strap-shaped (linear in the 2 preceding species), 6–8 in. long: segms. pale red or rosy; stamens half as long as the segms. Coast region, S. Afr.—Less known in cult. than the others.

WILHELM MILLER.

LAPÓRTEA (François L. de Laporte, entomologist of the nineteenth century). *Urticàceæ.* Perennial herbs, shrubs, or trees, a few species of which are sometimes grown in glasshouses for the showy foliage or fruits.

Leaves alternate, often large and variously colored, mostly dentate: fls. monœcious or diœcious, clustered in loose cymes, small and inconspicuous; sterile fls. with a 4–5-parted perianth (or separate sepals), 4 or 5 stamens, and rudiment of an ovary; fertile fls. with 4 sepals or 4-lobed perianth, the 2 outer usually much smaller: fr. an ovate or oblique compressed achene.—Species 40–50, widely scattered, mostly of tropical countries; one *L. canadense,* reaches to Canada. They are provided with stinging hairs, and must be handled with caution. The horticultural species are prop. by seeds, and also by cuttings started in heat. The generic name Laportea is retained in the "nomina conservanda" of the International Code as against Urticastrum.

Three species-forms appear to be best known in cult., as follows: **L. Schómburgkii,** Bull. Ornamental-lvd. plant (usually known as var. *versicolor*) from Polynesia: lvs. large, with fleshy petioles and deciduous herbaceous stipules; blade deep green, with purplish rib and veins, mottled with gray-green and cream-white, sometimes one-half being creamy white. G.Z. 20, p. 145. **L. gìgas,** Wedd. Tree, to 80 ft., India to Austral.: lvs. broadly cordate-ovate, obtuse or short-acuminate, more or less sinuate-toothed, 10–12 in. or more long. **L. moroìdes,** Wedd. Shrub or small tree of Queensland: lvs. broadly ovate, 6–8 in. long and nearly as broad, peltate at base, short-acuminate, prominently toothed: fr. mulberry-like, purple, borne beneath the crown of lvs. and remaining for nearly a year. B.M. 7057. Gn. 61, p. 71. Gt. 54, p. 289 (also 49, p. 68 as *L. gigas*). A showy greenhouse plant, worthy of attention except for the virulently stinging hairs.

L. H. B.

LÁPPA: *Arctium.*

LÁPPULA (diminutive of *lappa,* a bur). *Boraginàceæ.* Annual, biennial or perennial herbs, of probably forty species, some of them native in North America. They are related to Myosotis, but lack sufficient horticultural character to bring them into the trade-lists. In the older manuals they are known under the name Echinospermum. The four little nutlets are burs and adhere to clothing, and the plants are mostly weedy in appearance. The flowers are blue or whitish, small, in spikes or racemes.

LARCH: *Larix.*

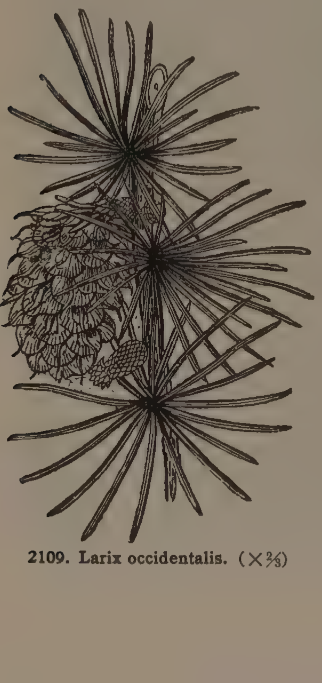
LARDIZABÀLA (after the Spanish naturalist Lardizabal y Uribe). *Lardizabalàceæ.* Two shrubby evergreen climbers in Chile with once- to thrice-ternate lvs.: fls. diœcious, purple-brown; sepals 6, and 6 petaloid nectaries, sometimes called petals; the staminate fls. in pendulous racemes, with 6 connate stamens; the pistillate ones solitary, with 6 distinct sterile stamens and 3 cylindric ovaries, developing into oblong, many-seeded berries. The pulpy edible fr. is sold in the Chilean markets and cordage is made of the fibrous sts. Only the following species, which is similar to the well-known *Akebia quinata* but has short-stalked pointed lfts. in 3's, is cult. in S. Calif. for its handsome foliage and the odd-looking dark-colored fls.; it is readily prop. by cuttings of half-ripened wood under glass. **L. biternàta,** Ruiz & Pav. Lvs. twice ternate or on the flowering branchlets usually simply ternate; lfts. leathery, ovate, acute or mucronate, entire or with 1 or 2 almost spiny teeth, dark green and glossy above, paler and reticulate beneath, 2–4 in. long: staminate fls. about 1 in. across, purple-brown, in a dense, about 15-fld. drooping raceme; the petaloid nectaries lanceolate, white, the pistillate fls. slightly larger, solitary, slender-stalked: fr. oblong, 2–3 in. long. Winter or spring. B.M. 4501. G.C. III. 52:467. Gn. 28, p. 489. J.F. 1:5. B.H. 3:339. P.M. 1, p. 28.

Alfred Rehder.

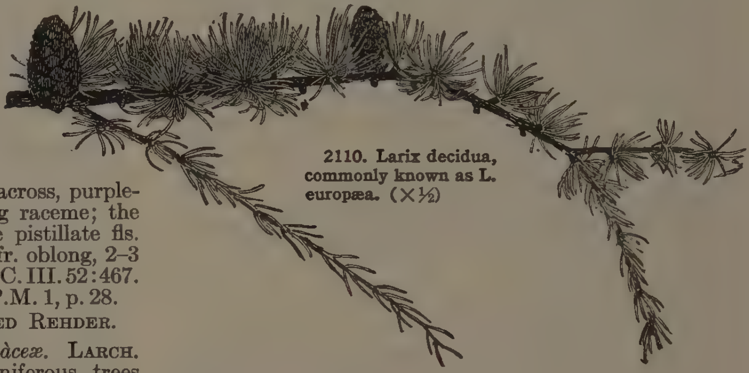
LÀRIX (ancient Latin name). *Pinàceæ.* Larch. Tamarack. Ornamental deciduous coniferous trees chiefly grown for their bright or light green foliage and regular habit.

Branches whorled, at least while young: lvs. linear, in crowded clusters on short spurs except on the leading shoots where they are spirally arranged: fls. monœcious; staminate fls. small, globose to oblong, solitary, consisting of numerous short-stalked, spirally arranged anthers; pistillate fls. larger, consisting of several or numerous scales, with 2 naked ovules at the base, each scale borne in the axil of a much longer bract: cone with woody, 2-seeded scales, persistent on the axis; seeds with large, thin wings, ripening the first year.—About 10 or 12 species in the colder regions and the high mountains of the northern hemisphere.

The larches are handsome trees of regular pyramidal habit, but in old age becoming sometimes irregular; they are particularly handsome in spring with their light green tender foliage and studded with their usually bright purple pistillate flowers. They are all hardy North except the Himalayan *L. Griffithii*, and are often planted as park trees, chiefly for the light green foliage and the regular conical, or in some varieties pendulous, habit. The most beautiful is probably *L. leptolepis*, with the foliage turning bright yellow in fall, while the others assume only a pale yellow color. They are also very valuable forest trees, especially for the northern and mountainous regions; no forest tree goes farther north than the larch, reaching in North America 67° and in Siberia 72° of latitude. The wood is hard, heavy and very durable, and much used for construction, that of *L. occidentalis* being considered the best of all American conifers. From the European larch turpentine is obtained. The bark contains tannin, and an extract is used for tanning leather. The larch grows in almost any kind of soil, including clay and limestone, and prefers a somewhat moist, but well-drained soil and an open situation; the American larch grows well even in swamps. Unfortunately several insects and fungi prey on the larch, and sometimes do considerable damage, especially the leaf-eating larvæ of some moths. Propagation is usually by seeds sown in spring, and the young seedlings shaded; varieties are grafted on seedlings, mostly on those of *L. decidua* (*L. europæa*), either outdoors by whip- or cleft-grafting or in the greenhouse by veneer-grafting; they may also be increased by cuttings of nearly ripened wood under glass or by layers, but this method is rarely practised.



2109. Larix occidentalis. (×⅔)



2110. Larix decidua, commonly known as L. europæa. (×½)

A. *Bracts longer than the scales: scales numerous, stiff, spreading or recurved after maturity.*

occidentàlis, Nutt. Fig. 2109 (adapted from Pacific R. R. Report). Tall tree, to 150 ft., with dark-colored bark, becoming bright cinnamon-red on older trunks, and with short, horizontal branches, forming a narrow pyramidal head: branchlets pubescent when young: lvs. rigid, sharply pointed, triangular, keeled beneath, 1–1¾ in. long, pale green: cone oblong, 1–1½ in. long; scales orbicular, almost entire, tomentose beneath. Brit. Col. to Mont. and Ore. S.S. 12:594. G.F. 9:497. Gt. 20:685, figs. 8–10. G.C. II. 25:652. B.H. 22:8, figs. 3–5. B.M. 8253. R.H. 1909, pp. 252, 253.

AA. *Bracts much shorter than scales.*

B. *Lvs. with 2 white lines beneath: scales numerous, reflexed at the apex.*

leptólepis, Murr. (*L. Kaémpferi*, Sarg., not Carr. *L. japónica*, Carr.). Tree, to 80 ft., with horizontal branches, forming a pyramidal head: branchlets yellowish or reddish brown, glabrous and glossy; spurs short and globular: lvs. rather broad, obtuse, soft, ½–1½ in., light or bluish green: cones ovate-oblong, ½–1½ in. long, with emarginate, roundish ovate scales. Japan. S. I. F. 1:2. G.C. II. 19:88; III. 40:290. G.W. 8, p. 496. Gt. 20:685, fig. 5. B.H. 22:8, fig. 2.—The handsomest of the larches as a lawn tree. Var. **mìnor,** Murr. (var. *Murrayàna*, Maxim. *L. japónica*, Murr., not Carr.). Dwarfer form with smaller cones. Gt. 20:685, fig. 2. B.H. 22:9, fig. 4. Var. **prostràta,** Beissn., a prostrate form.

BB. *Lvs. without white lines, very narrow: scales erect-spreading, straight or slightly incurved at the apex.*

C. *Scales usually puberulous or finely tomentose, slightly incurved at the apex, numerous.*

decídua, Mill. (*L. europæa*, DC. *L. Làrix*, Karsten). European Larch. Fig. 2110. Tree, to 100 ft., with pyramidal, later often irregular, head: bark dark grayish brown: branchlets slender, glabrous, yellowish: lvs. compressed, triangular, soft and obtuse, bright green, ¾–1¼ in. long: pistillate fls. purplish: cones ¾–1½ in. long, with many almost orbicular scales, usually puberulous, or glabrous on the back, loosely appressed at maturity. N. and Cent. Eu. F.E. 29:117. H.W. 1:3, pp. 108–112. M.D.G. 1908:316, 317. G.W. 9, p. 512. Gt. 20:684, fig. 3. B.H. 22:7, fig. 1. Var. **péndula,** Koch (*L. europæa* var. *péndula,* Lawson. *L. americàna* var. *péndula,* Loud.). With pendulous branches; sometimes confounded with the American larch. Gt. 20:684, fig. 11. B.H. 22:8, fig. 1. Gn. 35, p. 245; 39, p. 84. Var. **fastigiàta,** Koch (*L. europæa* var. *fastigiàta,* Beissn.). Of columnar habit. Var. **virgàta,** Hayek (*L. europæa* var. *virgàta* Hempel & Wilhelm). Branches long and tortuous, very sparingly branched. M.D. 1905:10. H.W. 1, p. 113.—A hybrid of this and the preceding species has been received from Dunkeld, Scotland, and is now growing at the Arnold Arboretum. It is of vigorous growth, but has not yet produced cones.

sibírica, Ledeb. (*L. europæa* var. *sibírica,* Regel, and var. *róssica,* Regel). Tree, to 120 ft., with straight slender st. and rather short ascending branches: branchlets yellow: buds grayish brown and dark brown or nearly black at the base: lvs. linear, 1–1½ in. long: pistillate fls. usually green, sometimes whitish or brownish: cones ovate-oblong, usually 1½ in. long; scales fewer and larger than in the preceding species, finely tomentose on the back, half-spreading at maturity. N. E. Russia to Siberia. Gt. 20:684, figs. 1, 2. B.H. 22:7, figs. 2, 3.

cc. *Scales glabrous, striate, straight at the apex, half-spreading at maturity, usually rather few.*

larícina, Koch (*L. americàna,* Michx. *L. microcárpa,* Desf. *L. péndula,* Salisb.). Tamarack. Hackmatack. Tree, to 60 ft., with horizontal branches, forming a narrow pyramidal head, sometimes broad and open on older trees; bark reddish brown: branchlets slender, glabrous, reddish yellow, often bloomy: buds reddish brown: lvs. like those of the former, but of light bluish green color: cones small, oval or almost globular, ½–¾in. long; scales few to 20, almost orbicular and entire, glabrous. Canada, south to Pa., west to Ill. and Manitoba. S.S. 12:593. Em. 106. Gt. 20:684, fig. 7, 8. B.H. 22:10, figs. 2, 3.

dahùrica, Turcz. (*L. Cajánderi,* Mayr). Tree, to 70 ft., of fairly regular habit while young, old trees usually irregular with wide-spreading branches: branchlets bloomy: buds yellowish brown, darker or nearly black at the base: lvs. linear, about 1½ in. long: cones small, ¾–1 in. long; scales orbicular or ovate, rounded or emarginate at the apex, lustrous, about 20 or more. E. Siberia. Gt. 20:684, figs. 9, 10. B.H. 22:9, figs. 5, 6. Var. **Príncipis Ruppréchtii,** Rehd. & Wilson (*L. Príncipis Ruppréchtii,* Mayr). Cones larger, to 1½ in. long; scales more numerous, truncate at the apex; bracts at least on the lower part of the cone more than half as long as the scales. N. China. G.W. 10, p. 566.

L. chinénsis, Beissn.=L. Potaninii.—*L. Gríffithii,* Hook. f. & Thoms. Pyramidal tree, to 60 ft., with spreading and pendulous branches: lvs. soft, obtuse: cones 2–3 in. long, oblong, with exserted and reflexed bracts. Himalayas. F.S. 12:1267–68. R.H. 1868, p. 371. Gt. 20:685, figs. 1–4. B.H. 22:10, figs. 4–7. G.C. II. 25:719; 26:465; III. 41:130, 131. B.M. 8181.—*L. Kaémpferi* Carr.=Pseudolarix Kaempferi.—*L. Kaémpferi,* Sarg.=L. leptolepis.—*L. kurilénsis,* Mayr (L. dahurica japonica, Regel). Allied to L. leptolepis, to 70 ft.: branches wide spreading; young branchlets deep bluish red, puberulous: lvs. rigid: bracts as long or somewhat shorter than scales. N. Japan. S.I. F. 2:1. G.W. 6, p. 499 (habit).—*L. Lỳalli,* Parl. Allied to L. occidentalis, but lower: young branchlets tomentose: lvs. quandrangular: young cones deep purple, the scales with fringed margin. Brit. Col. to Wash. S.S. 12:595. G.C. II. 25:653; III. 23:357. Gt. 20:685, figs. 11–13. B.H. 22:9, figs. 1–3. M.D.G. 1905:129 (habit).—*L. Mastersiàna,* Rehd. & Wilson. Allied to L. Griffithii. Tree, to 60 ft.: lvs. bright green, ¾–1⅓in. long: cones about 1½ in. long: bracts long exserted and reflexed, gradually narrowed into a mucro. W. China.—*L. olgénsis,* Henry. Allied to L. kurilensis, but scales pubescent. Amurland.—*L. Potanínii,* Batal. (L. chinensis, Beissn. L. thibetica, Franch.). Allied to L. occidentalis. Tree, to 80 ft.: branchlets glabrous: lvs. acute or obtusish, about 1 in. long: cones oblong-ovate, 1–2 in. long: bracts lanceolate, exceeding the nearly orbicular scales; scales spreading at maturity. W. China. G.C. III. 39:178.—*L. thibética,* Franch.= L. Potaninii.

Alfred Rehder.

LARKSPUR: *Delphinium.*

LÀSIA (Greek, *rough* or *prickly,* referring to the aculeate caudex, scape and foliage). *Aràceæ.* Two perennial herbs, woody at the base, allied to Dracontium and Cyrtosperma, not tuberous, with a more or less decumbent caudex, native in E. India, Ceylon, Java, Cochin-China. **L. spinòsa,** Thwaites (*Dracóntium spinòsum,* Linn. *Pòthos spinòsus,* Ham. *Làsia heterophýlla, L. Zóllingerii, L. Jénkinsii, L. Hérmannii* and *L. desciscens,* Schott), is offered abroad. It is a glasshouse subject: caudex about 1¼ in. thick, prickly: petioles 9–18 in. or more long, prickly; blade variable in shape, hastate or entire, or deeply pedately pinnatipartite: spathe 6–10 in. long, the upper part rolled into a tail-like extension, the open or spadix-bearing part short. E. India.

L. H. B.

LASIAGRÓSTIS: *Stipa.*

LASIÁNDRA: *Tibouchina.*

LASTHÈNIA (name of a woman who was a pupil of Plato). *Compósitæ.* Low, slightly succulent annuals, glabrous or only puberulent, with opposite lvs. and numerous inch-wide heads of yellow fls. in early summer: rays 5–15; receptacle conical or even subulate, with projecting points bearing the narrow flattened achenes; pappus none, or of 5–10 scales: involucral bracts making a bell-shaped or hemispherical cup.—Species about 6. Ore. and Calif., and Chile.

glabràta, Lindl. (*L. califórnica,* Lindl. *Hologýmne glabràta,* Bartl.). Height about 1 ft.: lvs. linear or lanceolate, usually 1–4 in. long, some sheathing at base: peduncles long, somewhat enlarged below the erect head; pappus none. Calif. B.M. 3730. B.R. 1780, 1823.—The plant cult. under this name is likely to be *Baeria gracilis,* which see. In Lasthenia the bracts of the involucre are united to form a green cup with toothed border, while in Baeria the bracts are not united.

Harvey Monroe Hall.

LASTRÈA (C. J. L. Delastre, Austrian botanist). *Polypodiàceæ.* A name commonly used in the trade, especially in England, for species of Dryopteris. Also spelled *Lastræa.* On the basis of priority it has no claim to recognition, as it was established by Bory in 1824, while we have Nephrodium, 1803; Aspidium, 1801; Tectaria, 1800; Polystichum, 1799, and Dryopteris, 1763.

The following additional species properly classified under Dryopteris (Vol. II, p. 1078) are in the American trade under the name Lastrea (the combinations are for Dryopteris, not Lastrea):

A. *Lowest pinnæ reduced to auricles: texture thin.*

sáncta, Kuntze. Lvs. 6–9 in. long, 1–2 in. wide on short slender stalks; lower pinnæ very much reduced; under surface glandular. W. Indies.

palústris, Kuntze. Lvs. 2–3 ft. long, 8–12 in. wide, on long straw-colored stalks; lower pinnæ reduced, the upper ¾in. wide, cut down to the rachis into linear-oblong lobes. Brazil.

montàna, Kuntze. Lvs. 1½–2 ft. long, 6–8 in. wide; lower pinnæ greatly reduced to mere auricles; upper pinnæ 1 in. wide, cut into close blunt lobes. Eu., W. N. Amer. A var. **cristàto-grácile** is also cult.

AA. *Lower pinnæ scarcely reduced: texture firm.*

rígida, Kuntze. Stalks stout, densely scaly: lf.-blades 1–1½ ft. long, 4–6 in. wide, oblong-lanceolate, the lower pinnæ not reduced; segms. with mucronate teeth. Eu. Var. **argùta** is native and wild in Calif., and is often considered a distinct species.

lépida, Moore. Lf.-blades 1½ ft. long, 6–7 in. wide, ovate, bipinnatifid or bipinnate, the lower 4 or 5 pairs slightly smaller: indusia hairy. Of greenhouse origin.

Other species cult. under the name Lastrea, as *L. aristàta* and *L. Richardsii*, belong to the genus Polystichum, which see.

L. M. UNDERWOOD.
R. C. BENEDICT.†

LATÀNIA (East Indian name). *Palmàceæ.* Tall, spineless palms, with solitary robust annular trunks.

Leaves ample, terminal, long-petioled, suborbicular, palmately flabelliform, plicately multifid; segms. smooth or spiny on the margins; rachis short; petiole 3-sided, concave above; ligule shell-shaped; sheath short: spadices many feet long, compressed at the base and branches, sheathed with incomplete sheaths; staminate-fld. branches cylindrical, digitately arranged at the ends of the branches, very densely clothed with imbricated bracts; pistillate portion somewhat twisted, few-fld., sheathed with very broad dentate bracts; staminate fls. in tiny pits and half-exserted beyond the bracts, the perianth smooth and shining; pistillate fls. larger: drupe globose, obovoid or pear-shaped, yellow.—Three species of fan palms from the Mascarene Isls. *L. borbonica* is one of the dozen commonest trade names among palms, but the seeds offered under this name are said to be almost invariably those of *Livistona chinensis*. *Latania borbonica* of the botanists is properly *Latania Commersonii*, which has 3-seeded frs., while those of *Livistona chinensis* are 1-seeded. Allied genera are discriminated under *Hyphæne*. G.C. II. 25:75.

Latanias are essentially warmhouse palms and require moderate shading through the greater part of the year, and also an abundance of water. A well-drained and rather light compost is most suitable for them, and if the soil at the time of repotting is of the same temperature as the house in which the plants are grown, there will be less risk of a check to the delicate rootlets. They should have a night temperature of not less than 60° to 65°. As they grow very freely, it is advantageous to plant out if possible. Propagate by imported seeds sown over strong bottom heat. Bone-meal is a good fertilizer for these palms. *L. Commersonii* is a particularly striking palm, the leaf-stems being quite long, smooth, and colored bright crimson, as are also the ribs of its fan-like leaves, this coloring being especially bright on the young foliage. *L. Loddigesii* is the strongest grower of the genus, the leafstalks reaching a length of about 8 feet, usually chocolate-colored and quite glaucous, the leaves thick and leathery and their ribs reddish while young, though never developing such bright tints as those of the preceding species. *L. Verschaffeltii* is also very attractive, though possibly a little more delicate than the other two, its leafstalks being long and rather slender, and orange-yellow in color, the ribs of the leaflets also yellow and the leaves themselves of a light shade of green. (W. H. Taplin.)

A. *Lvs. glaucous.*

Lóddigesii, Mart. (*L. glaucophýlla*, Hort.). About 50 ft. in nature, cult. specimens 10–20 ft.: lvs. 3–5 ft. long, very glaucous, primary veins slightly tomentose beneath, tinged with red, especially in young plants; segms. 2 ft. long, less than 3 in. wide, unequally acuminate, the edges spiny in young plants; petioles 3–4½ ft. (or more) long, tomentose, entire in the mature, spiny in the young plant: spadix 3½–4 ft. long: drupe pear-shaped, 3-angled, 2½ in. long, 1¾ in. thick. Mauritius.

AA. *Lvs. not glaucous.*

B. *Petiole densely tomentose, with an orange margin.*

Verschafféltii, Lem. (*L. aùrea*, Duncan). Wild specimens 40 ft.; about half this in cult.: lvs. pale green, 4½–5 ft. long, the segms. 2½ ft. long, above 2 in. wide, acuminate, the entire margins and veins slightly tomentose beneath; petioles 5–8 ft., densely tomentose, with entire, orange margins, spiny in young plants: spadix 4–8 ft. long: drupe slightly 3-angled, 2 in. long, 1½ in. wide. Isl. Rodriguez. I.H. 6:229. G.C. III. 31:152.

BB. *Petiole red, slightly tomentose.*

Cómmersonii, Gmel. (*L. rùbra*, Jacq. *L. borbónica*, Lam., not Hort.). Lvs. 5–5½ ft. long, dark green above, paler beneath; segms. lanceolate, acuminate, 2 ft. long, 3¼–3½ in. wide, their margins entire, spiny in young plants, veins and margins tinged with red; petiole 4–6 ft., slightly tomentose, the margins smooth, spiny in young plants: spadix 3–6 ft. long: drupe globose, 1½–1¾ in. diam. Mauritius. Not A.F. 4:567 and 7:127, A.G. 13:141; 15:389 and 19:557, V. 9:199, G. 2:459, all of which are *Livistona chinensis.*

L. erécta and *L. variegàta* are trade names. Any specimens in cult. will probably be found to be varieties of some of the above.

N. TAYLOR.†

LATHRÆA (*hidden*, Greek, alluding to habitat). *Orobanchàceæ.* TOOTHWORT. Root-parasities without green herbage, sometimes sown or encouraged in shrubberies where their host-plants grow.

Allied to Orobanche, but the calyx with 4 broad short teeth or lobes rather than with 2 or 4 pointed sepals, and the fls. not regular: low herbs, brownish, flesh-colored or bluish, bearing many small fls. in scaly racemes or spikes, the sts. usually simple and erect; stamens 4, in 2 pairs, with 2-celled anthers: caps. 1-celled, opening by 2 valves.—Species 5. Eu., Asia, Japan. In N. Amer., the family is represented by Orobanche (the broom-rape), Conopholis (squaw-root or cancer-root), Epifagus or Leptamnium (beech-drop), Aphyllon or Thalesia, Fig. 231, Vol. 1, by some united with Orobanche, and Boschniakia of the far Northwest. They are scarcely horticultural subjects, although some of the species seem to establish themselves readily when planted where there are proper hosts.

Two species are more or less recorded in horticultural literature. *L. Clandestìna*, Linn. (*Clandestìna rectiflòra*, Lam.), Eu., has very many densely crowded sts. 4–6 in. high, from densely interlaced rhizomes: fls. pale gray-purple or violet, darker purple on the lower lip, 2 in. long and erect in racemes 3–5 in. high. Grows on willow and poplar, and other hosts. G.C. III. 35:292, 293, showing a group established on roots of beech and willow. G. 36:242. A showy species. *L. Squamària*, Linn. (*Squamària Orobánche*, Scop.), Great Britain to Russian Asia: pale rose-color, with flesh-colored or faintly bluish fls. which are streaked with purple or dark red: rootstock scaly, fleshy, creeping: fls. many, nodding, short-stalked or in a dense spike. On roots of hazel.

L. H. B.

LÁTHYRUS (name used by Theophrastus for some leguminous plant). *Leguminòsæ.* Annual and perennial, climbing and upright herbs and shrubby plants with pinnate leaves, half-sagittate stipules and showy papilionaceous flowers.

Stems flat or winged, in some species: lvs. equally pinnate, ending in a tendril or in a point; lfts. 2 or several; stipules leafy, large and prominent, half-sagittate: fls. solitary or racemose, on long axillary peduncles; calyx oblique-campanulate, 5-parted, the upper teeth often shorter; corolla dark blue, violet, rose, white or yellow, or a union of these, the standard large, broadly obovate or roundish, notched, with a short claw, the wings falcate-obovate or oblong, the keel shorter than the wings, incurved, obtuse; stamens diadelphous (9 and 1) or monadelphous below; ovary 1-celled, the pod several-seeded; style curved, usually twisted, flattened, hairy along the inner side: pod flat or terete, 2-valved, dehiscent.—A genus according to the Index Kewensis, of more than 200 species, occurring in the northern hemisphere, Amer., Eu., Asia, and in Afr. and

S. Amer. *Orobus niger* and *O. vernus* are common garden names, but Bentham & Hooker, also Engler & Prantl, make Orobus a subgenus of Lathyrus, characterized in part by the lack of tendrils. See *Orobus.*

The genus is best known by the sweet pea. Most other forms are perennial, although some of these are cultivated as annuals. All are free-growing plants, so independent in their ways that they require a place to grow by themselves, apart from other plants of like habit or size. Hence they are to be grown alone, on trellises or against walls, in rock-gardens, or allowed to form a wild tangle among strong shrubs. The chief value of the annuals is for cut-flowers, although their part in the garden is not to be ignored. As a temporary screen in summer for shutting out unsightly objects, they are valuable, or for quickly covering trellises or rough places otherwise unsightly.

2111. Lathyrus tingitanus. Sometimes sold as a form of sweet pea. (×⅓)

The perennials are of comparatively easy cultivation, succeeding in any garden soil. The annuals are more exacting in their requirements, demanding a moderately rich garden soil, abundant moisture, coolness and depth for their roots, and open sunlight. All are grown from seed, sown very early in the open to secure the required coolness for the roots. The perennials are propagated, in addition, by division, special varieties being increased by cuttings in the fall, after the flowering season, or in spring from old plants stored in the greenhouse. The roots of perennials are long and fleshy, and, when once established, usually continue for years without attention.

A. *Habit climbing: lvs. tendril-bearing.* (*Lathyrus.*)

B. *Plants annual: lfts. 1 pair.*

1. **odoràtus,** Linn. Sweet Pea. St. rough-hairy, winged: lfts., oval or oblong, mucronulate; stipules lanceolate: peduncle 2–4-fld., much longer than the lvs.; fls. in shades of blue, red, yellow and white, fragrant, the shield large and showy, expanded, sometimes "hooded:" pod 1–2 in. Summer. Italy. B.M. 60.—For cult. and varieties, see *Sweet Pea.*

2. **tingitànus,** Linn. Tangier Scarlet Pea. Fig. 2111. Sts. spreading, winged, glabrous, 3 ft. long: lfts. linear-lanceolate, obtuse, mucronulate; stipules lanceolate: peduncle 2-fld., longer than the lvs.; fls. 1 in. long, dark red-purple; shield large, purple, wings and keel bright red: pod 4–5 in. long. June, July. W. Mediterranean region. B.M. 100.—An earlier annual than the sweet pea, and because of its vigor will run it out. It has been grown for forage.

BB. *Plants perennial.*

C. *Lvs. with 1 pair of lfts.*

D. *Stipules narrow.*

3. **grandiflòrus,** Sibth. and Smith. Everlasting Pea. Two-flowered Pea. Fig. 2112. St. winged, 4–6 ft. long: lfts. large, ovate, obtuse, mucronulate, undulate; tendrils branched, short; stipules small: peduncles, 2–3-fld., longer than the lvs.; shield large, obcordate, notched, broad, rose-purple, wings dark purple: pod linear, 3 in. June, July. S. Eu. B.M. 1938.—Larger vine than *L. latifolius*, but weaker and less rampant. Fls. as large as those of the sweet pea. Free-flowering, succeeding in any soil, not requiring much light. Adapted to banks, along path-margins in woods, among strong shrubs, and as a covering for rocks.

4. **sylvéstris,** Linn. Flat Pea. St. straggling or climbing, 3–5 ft. long, stout, winged, glabrous, with creeping rootstock: lfts. linear-lanceolate, thick, with winged lf.-stalk: peduncle 3–6-fld., equaling the lvs.; fls. ½in. long; standard rose, with green spot on its back; wings purple at summit; keel greenish: pod lanceolate, 2–3 in. long. All summer. Eu.—Inferior ornamentally to other perennials; sometimes mentioned (in the domestic var. *Wagneri*) as a forage plant and for plowing under in a green state as a fertilizer. Grows well on poor, unimproved sandy soil, and is unaffected by frosts and droughts. For garden cult., it may be sown in a seed-bed and transplanted when of suitable size. Its seeds in the wild state are said to be to some degree unhealthful, but in the cult. form this quality has been bred out.

5. **rotundifòlius,** Willd. Persian Everlasting Pea. Low-growing, winged species: lfts. ovate; stipules toothed: peduncles many-fld., longer than the lvs.; fls. large, rose-pink. June. Russia and the East. B.M. 6522.—A species of easy cult. requiring a cool, shady and sheltered position. Adapted to stony banks.

6. **undulàtus,** Boiss. (*L. Sibthorpii*, Baker). Sts. twining, broadly winged: lfts. oblong: peduncle 5–6-fld.; fls. a mauve-red.—A form intermediate between *L. latifolius* and *L. rotundifolius*. A somewhat tender species, said to be 6 weeks earlier than any other.

DD. *Stipules broad.*

7. **latifòlius,** Linn. Everlasting Pea. Perennial Pea. Fig. 2113. St. winged, 4–8 ft.: lfts. ovate-elliptic or ovate-lanceolate, somewhat glaucous, mucronate, 2–3 in. long; tendril branching: peduncle many-fld., longer than the lvs.; fls. rose, large: pod flat, 4–5 in. long. Aug. Woods of Eu.—This is the common perennial pea, and one of the hardiest and most easily cult.

species, thriving almost anywhere, even among flags and boulders. A rampant grower, it is a good trellis plant, and is adapted as a cover to wild, rough places, as a rock-garden, where it scrambles over bushes and stones. It succeeds in shade and grows rapidly, but, like all species of Lathyrus, it is impatient of removal, owing to the size and length of its roots. It is not fragrant. Its varieties are not clearly defined. Var. **álbus,** Hort., the white form, is adapted to the same uses as the type, and is, besides, valuable to florists who want white fls. in midsummer. Var. **spléndens,** Hort., dark purple and red, is said to be the best form of the type, but does not come true from seed. There is a striped form, also. Other trade names are vars. **albiflòrus, grandiflòrus, grandiflòrus álbus** and **magníficus** with large richly colored fls.

2112. Lathyrus grandiflorus. (×⅙)

8. **magellánicus,** Lam. Lord Anson's Blue. St. 3–5 ft. long, smooth, angled, somewhat branched: lfts. ovate or oblong-linear; tendrils branched; stipules cordate-sagittate, broad: peduncles long, 3–4-fld.; fls. dark purple-blue. June, July. Straits of Magellan. —A strong-growing, woody, almost evergreen species covered with a bluish bloom. Since it is a maritime plant, salt is said to assist its growth. It is sometimes regarded as an annual. Var. **álbus,** Hort., "Lord Anson's White," is the white form.

9. **pubéscens,** Hook. & Arn. A soft-hairy, diffusely-branching shrub: st. 4-angled: lvs. with rarely 2 pairs of lfts., ending in a stout trifid tendril. Extra Trop. S. Amer. from Valparaiso to Chiloe in Chile. G. 32:499.

cc. *Lvs. with more than 1 pair of lfts.*

10. **palústris,** Linn. Marsh Pea. Wing-stemmed Wild Pea. St. slender, 1–3 ft. long, glabrous or somewhat pubescent, often winged, rather erect: lfts. 2–4 pairs, oblong-lanceolate, acute, 1–2 in. long; tendrils branched; stipules small, lanceolate: peduncles 2–8-fld., scarcely longer than the lvs.; fls. purplish, ½in. long: pod 2 in. long. Summer. N. N. Amer. and N. Eu., in moist places.—A good bog-plant. Var. **myrtifòlius,** Gray (*L. myrtifòlius,* Muhl.). Myrtle-leaved Marsh-Pea. Has smaller, obtuse lvs., broader and larger stipules, the fls. pale purple. July, Aug. Banks of rivers, N. N. Amer. to N. C.

11. **marítimus,** Bigel. Sea or Seaside Pea. Beach Pea. St. stout, 1–2 ft. long, angled, decumbent: lfts. 3–6 pairs, ovate-oblong, thick, glaucous, nearly blue, 1–2 in. long; stipules lf.-like, broadly ovate and cordate-hastate: peduncles 6–10-fld., a little shorter than the lvs.; fls. purple; wings and keel paler, ¾in. long: pod 1½ in. long, hairy. May–Aug. Gravelly and sandy seacoasts throughout northern hemisphere.—A spreading plant with creeping rootstock and of rapid growth, very tenacious of life. A good plant in rock-gardens and in gravelly soil.

12. **venòsus,** Muhl. Showy Wild Pea. St. stout, 2–3 ft. long, finely pubescent, strongly 4-angled: lfts. 4–6 pairs, oblong-ovate, obtuse, often pubescent below, 2 in. long; stipules narrow, short: peduncle crowded, 8–16-fld., rather shorter than the lvs.; fls. purple, 6–8 lines long: pod smooth. June, July. Shady places and along streams, Canada to Ga.

13. **spléndens,** Kellogg. Pride of California. St. subshrubby, slender, more or less soft-pubescent: lfts. 4–6, ovate-oblong to linear, ½–1 in. long, acute; stipules narrow: peduncle 6–12-fld.; fls. pale rose or violet, large. Dry hills of coast ranges, S. Calif. Gn. 52:162.—A greenhouse plant 1 ft. long or more, becoming 8–10 ft. at home, where it dies down during the summer. Elsewhere it adapts itself to climate but is not hardy in N. U. S. Sometimes confused with a variety of *L. latifolius.*

14. **violàceus,** Greene. Sts. slender, shrubby below, 4–8 ft. high, acutely angled: lfts. about 12, elliptic, obtuse with reflexed tips: fls. in racemes, 10–14 in each, ¾in. long; violet-blue, banner veined with darker veins.—One of the most beautiful of the California species, native of Los Angeles County.

15. **lætiflòrus,** Greene. Wild Pea. Shrubby, 4–8 ft. tall: lfts. of firm texture, elliptic-lanceolate: fls. 1 in. long, fragrant, white faintly flesh-colored, the banner obcordate, veined with red. S. Calif.—Plant under bushes or on banks.

aa. *Habit not climbing: lvs. not tendril-bearing.* (*Orobus.*)

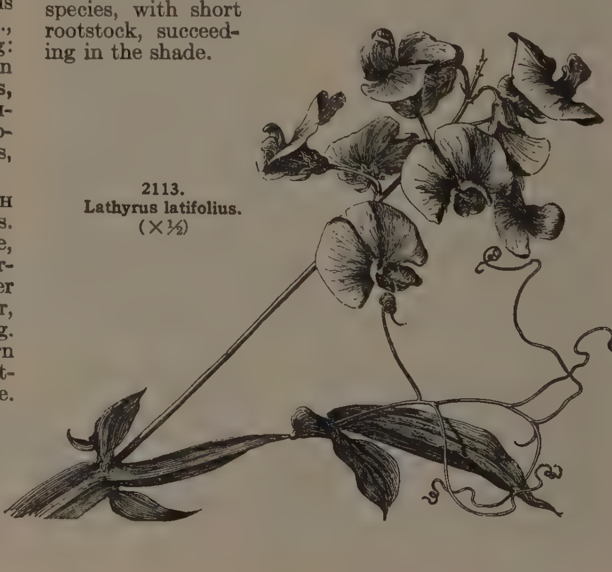
b. *Fls. yellow.*

16. **montànus,** Bernh. (*Órobus lùteus,* Linn. *L. lùteus,* Baker). St. simple, angled, smooth: lfts. 5–8 pairs, large, elliptic-lanceolate, pointed, glaucous below: peduncles many-fld., a little shorter than the lvs.; fls. large, orange-yellow. June, July. Forests of the Alps.—A shade-enduring species with fls. in erect, spike-like clusters and adapted to borders and rockeries.

bb. *Fls. not yellow.*

17. **polymórphus,** Nutt. Prairie Vetchling. St. rather stout, usually low, glabrous or finely pubescent, erect, a little woody at the base: lfts. 3–6 pairs, scattered, narrowly oblong, acute, thick, 1–2 in. long; stipules narrowly acuminate: peduncle 2–6-fld., a little longer than the lvs.; fls. purple, large. March–July. Grassy, alluvial plains, Colo. to New Mex. and Ariz.

18. **nìger,** Bernh. (*Órobus nìger,* Linn.). Black Pea. Black Bitter Vetch. St. erect or ascending, branched, angled, 1–2 ft. long: lfts. 6–8 pairs, elliptical or ovate, ½–1 in. long, light green, turning black when drying; stipules narrow, small: peduncles 6–8-fld., longer than the lvs.; fls. purple, small. June, July. Mountainous and rocky districts, Cent. Eu. B.M. 2261.—Slender species, with short rootstock, succeeding in the shade.



2113. Lathyrus latifolius. (×½)

19. **vérnus,** Bernh. (*Órobus vérnus,* Linn.). Spring Bitter Vetch. St. simple, somewhat pubescent, 1–2 ft. long: lfts. 2–3 pairs, ovate-acuminate, light green; stipules entire: peduncles 5–7-fld., shorter than the lvs.; fls. blue-violet; keel shaded with green, nodding. May, June. Hills and woods, S. and Cent. Eu. B.M. 521.—A compact, tufted plant, growing quickly in sun or a little shade; best in deep, sandy loam, in a sheltered position; hardy. Var. **álbus,** a white form, is rare. Var. **fláccidus,** Ser. (*Orobus fláccidus,* Rad.) has very narrow flaccid lvs.

20. **ornàtus,** Nutt. Fig. 2114. St. sometimes branched, glabrous, often glaucous: lfts. few pairs, lanceolate-linear, rigid and strongly veined; stipules entire: peduncles about 4-fld., longer than lvs.; fls. large, purple, very showy. Plains eastern base of Rocky Mts.

L. álbus, Linn. f. Root of clustered club-shaped fibers: lfts. 2–3 pairs, linear to lanceolate: fls. white or yellowish, standard sometimes purple, or rose on back. Eu.—*L. Cicera,* Linn., and *L. Ochrus,* DC., are annual forage plants.—*L. tuberòsus,* Linn., has been imported. It differs from all described above by having tubers. It is a native of the northern parts of the Old World, and bears red fls. which are generally fewer and smaller than those of L. sylvestris.

A. Phelps Wyman.
John W. Harshberger.†

LAUREL. Properly *Laurus nobilis,* but other broad-leaved evergreens have taken the name. The kalmias are known as laurels. The cherry laurel is *Prunus Laurocerasus,* and in America *P. caroliniana.* Portugal laurel is *P. lusitanica.* Ground laurel is Epigæa.

LAURÈLIA (from Laurus, because of resemblance in leaves). *Monimiàceæ.* Aromatic forest trees, 2 in Chile and 1 in New Zeal.: lvs. coriaceous, opposite, mostly serrate: fls. in axillary cymes or racemes, diœcious or polygamous, apetalous; perianth or calyx of male fls. with a short tube and 5–12 lobes in 2 or 3 series, and 4–12 stamens; perianth of other fls. narrower-tubed and elongating after fertilization, 3–5-cleft, the stamens reduced to scales or the outer ones perfect; carpels numerous, with solitary erect ovules: achenes small, included in the perianth.

serràta, Bert. Huanhuan Tree. Timber tree in southern parts of Chile, and hardy in parts of S. Ireland, to 70 ft., with fetid wood: lvs. broadly oblong-lanceolate or lanceolate, nearly or quite obtuse, glandular-serrate with open spreading teeth, bearing pellucid glands, aromatic: infl. axillary, cymose, simple or paniculate, the 8-parted perianth greenish yellow, the segms. equal; pedicels very short. B.M. 8279. G.C. III. 36:401 (as *L. aromatica*).

L. nòvæ-zealándiæ, A. Cunn. Tree, to 80 or 120 ft. high, and trunk 4–6 ft. diam., with radiating buttresses: lvs. to 3 in. long, oblong to obovate, coarsely and bluntly serrate: fls. in axillary racemes ½–1 in. long on silky pedicels: lvs. and young branches aromatic when bruised.—*L. sempérvirens,* Tul. (L. aromatica, Poir.). Chilean Laurel. Lvs. undulate-serrate with appressed teeth: infl. longer than in L. serrata and lax, perianth-segms. differing or subequal, fertile stamens usually exceeding 4; pedicels exceeding the fls.

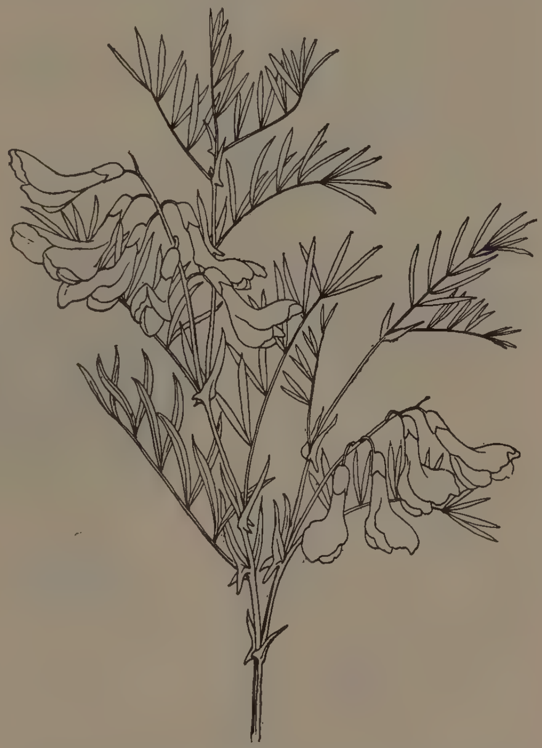
L. H. B.

LAURESTINUS: Popular name of *Viburnum Tinus.*

LAUROCÉRASUS: *Prunus.*

LAÙRUS (the ancient name). *Lauràceæ.* Laurel. Sweet Bay. The laurel or sweet bay tree of the florists is the most universal of evergreen tub-plants.

Laurus gives name to the family *Lauraceæ,* which includes Cinnamomum, Camphora, Persea, Sassafras, Lindera, Benzoin, and other genera. Many species have been referred to Laurus, but with the exception of two, these species are now placed in other genera. These two are *L. nobilis,* Linn. (the subject of this sketch), and *L. canariensis,* Webb & Berth., of the Canary Isls. They are small trees, with stiff alternate simple lvs.: fls. diœcious or perfect, small and inconspicuous, in small axillary umbels which in bud are inclosed in a globose involucre; perianth with a short tube and a 4-parted limb; stamens 8–12 or more, and staminodia often present (staminodia usually 4 in fertile fl.); ovary scarcely sunk in the receptacle, the style short: fr. a small berry.—**L. nóbilis,** Linn., the sweet bay, has stiff, dull green, entire, alternate lvs. lanceolate or lance-oblong in shape: yellowish fls. in early spring: succulent, purple, cherry-like frs. It is native to the Medit. region, sometimes attaining a height of 40–60 ft., but rarely assuming a true tree-like form. As a cult. subject, it is grown as a small standard tree, with a close-sheared top. The lvs. are sometimes used in cookery and the making of confections, because of their pleasant aromatic flavor. The wreaths with which the heroes of antiquity were crowned were made of laurel lvs. It is the laurel of history and poetry. Many other trees are known as laurel because of the similarity of their lvs. The cherry laurel is *Prunus Laurocerasus;* the Portugal laurel, *Prunus lusitanica;* laurel of the southern states, *Prunus caroliniana;* the laurel, or mountain laurel of Calif. is *Umbellularia californica.* The *Laurus Benzoin* of trade catalogues is *Benzoin æstivale; L. Sassafras* is the sassafras tree; *L. Camphora* is the camphor tree (see *Cinnamomum*). It should be said that the bay rum of commerce is not made from the sweet bay, as some persons suppose, but from a pimenta.



2114. Lathyrus ornatus. (×1)

The laurel endures abuse and neglect, the head can be trimmed to almost any shape, and the growth may be kept within small limits year after year. F.R. 1:669. (Fig. 2115.) It is, therefore, the most popular of plants for decoration of open-air or exposed restaurants, esplanades, architectural appurtenances, and the like. Although much used in America, it is still more popular in Europe. Of the European dealers one may order plants with heads trained to pyramids, cones, globes, and the like, and with bodies long or short. The plant will endure considerable frost. It is grown in the open in England: "The sweet bay bush in the farmer's or cottage garden comes with its story from the streams of Greece, where it seeks moisture in a thirsty land along with the wild olive and the arbutus. And this sweet bay is the laurel of the poets, of the first and greatest of all poet and artist nations of the earth—the laurel sacred to Apollo, and used in many ways in his worship, as we may see on coins, and in many other things that remain to us of the great peoples of the past" (Gn. 47, pp. 301, 307). Although so universally used, there are few important horticultural varieties,—the variegated-leaved and crisped-leaved (the crimped-leaved being sometimes known as *L. regalis*) forms being the best known. There is also a willow-leaved form (known as *L. salicifolia*). Propagated by cuttings, and sometimes by seeds. L. H. B.

Cultivation of bay trees. (H. A. Siebrecht.)

The sweet bay trees in their various trained forms of standard, globular, oval, conical and pyramidal shape, are almost indispensable in connection with the now prevailing architecture of our modern palaces of the Renaissance, Venetian, as well as Colonial and old English forms. Most of the leading architects require these formal and highly ornamental trees for the proper setting of their building designs.

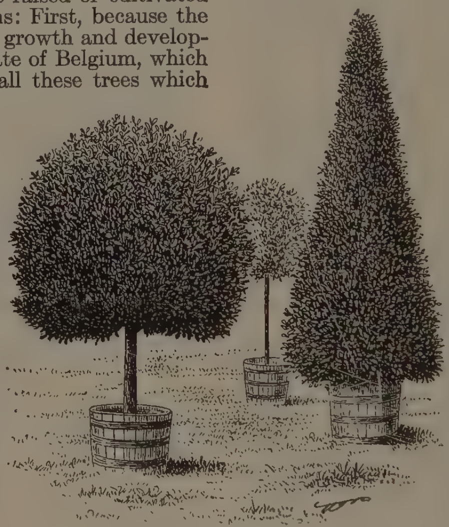
Very few such trees, if any, are raised or cultivated in this country, for several reasons: First, because the climatic conditions for their rapid growth and development are far inferior to the climate of Belgium, which country produces nine-tenths of all these trees which are used in all shapes and forms; second, the higher labor cost and expenses to produce them in this country prohibit the cultivation and constant training.

It is estimated that several hundred thousand bay trees are sold every year in Europe and America. They are mostly imported from Belgium and Holland, where they are cultivated as follows: Cuttings 3 to 4 inches long from well-ripened wood are put in sharp sand, either under bell-glasses or in glass cases. Bottom heat is not essential. After the cuttings have rooted, they are placed in small pots, in fairly rich sandy loam, with good drainage, and can then be put in a hotbed, with gentle bottom heat, where they will at once make a good strong growth. After this they are planted, as a rule, in nursery rows, in rich sandy soil, with perfect drainage. They will make a strong shoot 3 to 5 feet in length in one season. These shoots are tied up to stakes. At the end of the growing season and long before the cold weather sets in, these young plants, together with their stakes, are taken up and put into their winter quarters, which usually is a well-lighted and ventilated shed—an ordinary barn-like shed, sometimes built several feet into the ground and provided with skylights and ventilators. These plants are set in close rows and watered once or twice a week, according to the weather. Little or no fire heat is used in these sheds unless the weather gets extremely cold. The temperature is kept just above freezing. In the spring they are taken out and either potted and plunged in nursery rows, or planted out, as before. Plenty of water, rich peaty soil and the congenial moist atmosphere near the seacoast induces them to make a fast and luxuriant growth. Thus they are cultivated continually until the plants have been trained into the desired form, and as soon as they have attained enough of this form to show their character, which usually is from five to six years after propagation, they are planted in properly proportioned hardwood tubs and are then ready for the market, or to be further cultivated, perhaps for a good many years, until they grow into large specimens. The trees are cut back and trimmed into shape once a year, after the new growth is well matured.

The peaty muck soil in which they are grown abroad is very deceptive to Americans, and many fine trees have been ruined by not understanding its nature. Its dark color always makes it look moist. Sometimes when the soil looks moist enough the trees are really dying from drought.

In retubbing trees, there is danger of using for filling material a soil that is too heavy. The water then runs into the new soil, leaving the old soil dry. If the trouble is not detected soon the trees may be spoiled. The only thing to do in such cases is to comb out the old ball and cut back to live roots. The tree can then be planted in the open to gain a new set of roots, after which the top can be cut back to live wood. The tree may thus be eventually brought into a good shape again.

As a rule, bay trees are not good house plants. They do not like the dry heat of a dwelling. They can, however, stand considerable heat if they have plenty of fresh air and plenty of water. In spring and early summer, when they are making and finishing their growth, they can stand any quantity of liquid manure or of strong manure mulching, for they are great feeders. The cured leaves of the sweet bay are used in putting up packages of rice, and impart a rich and agreeable aroma.



2115. Laurus nobilis in tubs.

LAVÂNDULA (Latin, *lavo*, to wash; referring to the use of lavender in the bath). *Labiàtæ.* This group includes the lavender (*L. vera*), an ancient garden favorite because of its pleasant odor.

Perennial herbs, subshrubs or shrubs: lvs. commonly crowded at the base, pinnatifid or dissected: whorls 2–10-fld., crowded into long-peduncled cylindrical spikes, which are unbranched or branched from the base; fls. blue, violet or lilac; calyx tubular, 13–15-striated, 5-toothed; corolla-lobes nearly equal, or the posterior lip 2-cut, the anterior 3-cut; stamens 4, didynamous, declined, included in the tube; style shortly 2-cut at the apex.—Species upward of 20, Canary Isls. to India. In the N., winter protection should be provided for lavender. The plants of this genus grow naturally in dry and hilly wastes, except *L. multifida* which is found growing in peat.

A. *Spike loose: upper floral lvs. fertile, shorter than the calyx.*

B. *Lvs. not densely woolly.*

vèra, DC. (*L. angustifòlia*, Moench). LAVENDER. Subshrub, 1–3 ft. high: lvs. oblong-linear or lanceolate, entire; younger ones often clustered in the axils, white-tomentose, revolute at the margins; older ones greener, 1–1½ in. long: spikes interrupted; whorls 6–10-fld. Summer. Perhaps a form of *L. Spica*. Var. **compácta,** Hort. (var. *compácta nàna*, Hort.). Compact form: larger, deeper-colored fls., blooming 3 weeks earlier than type: 9 in. Rock-garden or border.

Spìca, Cav. Dwarfer than the true lavender, whiter, the lvs. more crowded at the base of the branches, spike denser and shorter. The floral lvs. are lanceolate or linear (rhomboid-ovate acuminate in *L. vera*), and the bracts are linear-awl-shaped, shorter than the calyx, while in *L. vera* the bracts are almost absent. Medit. region.

BB. *Lvs. densely woolly.*

lanàta, Boiss. Differs also from the preceding in having much longer and less crowded spikes. Spain. It grows 1–2 ft. high and needs winter protectioin in N. J.

AA. *Spike dense: upper floral lvs. sterile, comose.*

B. *Lvs. entire.*

Stœchas, Linn. Shrub, 2–3 ft. high: lvs. tomentose, about ½in. long: spikes short-peduncled, densely comose; fls. dark purple. Medit. region. Cult. in S. Calif.

BB. *Lvs. pinnate-dentate.*

dentàta, Linn. Lvs. pubescent: spikes long-peduncled; fls. deep purple. Medit. region. B.M. 400.—Intro. 1900 by Franceschi.

multífida, Linn. Cut-leaved Lavender. Herbaceous biennial, evergreen, 1–2 ft. high: lower lvs. petioled, upper sessile; lfts. decussately pinnatifid, hoary: spike simple, square, spiral: fl.-lvs. ovate, nerved, villous: fls. lilac. Calabria and Canary Isls.—Prop. by seed. Summer to fall. Not widely cult. Offered in S. Calif.

Wilhelm Miller.
A. C. Hottes.†

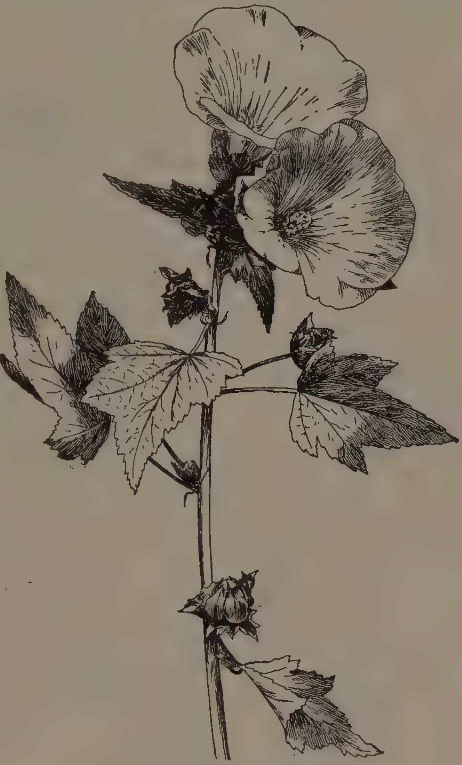
Cultivation of lavender. (M. G. Kains.)

In the eastern United States, lavender is grown in but few gardens, but in California, where climatic and soil conditions seem favorable, it is more commonly planted, although not on a commercial scale. The dry soil of that state and the light limestone soil of the Black Belt of Alabama and adjacent states seem to be most inviting to this industry.

The generic name is derived from the ancient use of its flowers and leaves in bath perfumery. The flowers long retain their strong fragrant odor after drying, and upon distillation yield a lemon-yellow very fluid oil of aromatic, bitterish, burning taste. Though this is officinally credited with stimulant and tonic properties, it is seldom administered in the pure state. Its chief uses are in the manufacture of perfumery, aromatic vinegar and lavender water, an alcoholic solution of the oil and other odorous substances. For these purposes, English oil has long commanded the highest price, but recently the French product has been claimed superior. Though all parts of the plant are aromatic, and both leaves and flower-stems are used in oil manufacture, oil obtained in the first half hour of distillation from flowers alone is much superior to the later distillate and also to the oil obtained from a mixture of flowers and stems. These grades, and also the highly valued product of very dry seasons, are always sold separately.

Lavender is best propagated by cuttings of one season's growth taken with a heel of older wood, in late autumn or early spring. When set 3 to 4 inches asunder in rather moist soil and shaded, they strike more readily and produce more symmetrical plants than older wood. Seed does not propagate desired varieties, and division is not advised, since plants so obtained are more susceptible to disease than those made from young-wood cuttings. After danger of frost, the one-year-old plants are set 4 feet asunder in rows 6 feet apart, running north and south. Closer planting and the hedge-method yield a smaller quantity of bloom. Dry, light, calcareous, even stony soils upon sites where sun and air are unimpeded by trees, favor this plant. Upon such fewer are injured by frost, and the oil is of superior quality. In moist soil so much water enters the plant as to enfeeble it, and upon rich lands yield and quality both suffer. Light fertilizing with stable-manure or ashes turned under in autumn, and spring harrowing, are advised. During the first year in the field the plants should be clipped to prevent flowering and to encourage stockiness. Vigorous plants so treated may grow to a height and a diameter of 5 feet, and when two to four years old produce secondary bloom-spikes after the general harvest, which usually occurs in early August. Plantations should be destroyed when four to six years old and the land rested with other crops before setting to lavender again. Cutting in clear weather, in early blossom, before the dew is off and at once distilling give best results; but no delay should occur. Cutting in wet weather, in the heat of the day, holding blossoms long before distilling and exposing them to the sun after cutting result in serious losses. One pound of flowers yields from one-half to one drachm of oil, and an acre from two to twenty-five pounds. The annual output of the stills of Grasse, France, is from 80,000 to 100,000 kilogrammes.

"Oil of spike," obtained from a broad-leaved, much whiter and smaller species (*L. Spica*), is less fragrant than true lavender oil, being analogous to oil of turpentine, with which it is often adulterated. It suggests the odor of rancid coconut oil. Officinally, it is credited with carminative and stimulant properties, and has been found useful in nervous languor and headache. It is used by artists in the manufacture of varnishes, by porcelain painters, and to a small extent in perfumery, mainly as an adulterant. From 20,000 to 25,000 kilogrammes are annually produced at Grasse. See also "Culinary Herbs" by M. G. Kains, 1912.



2116. Lavatera trimestris. (×½)

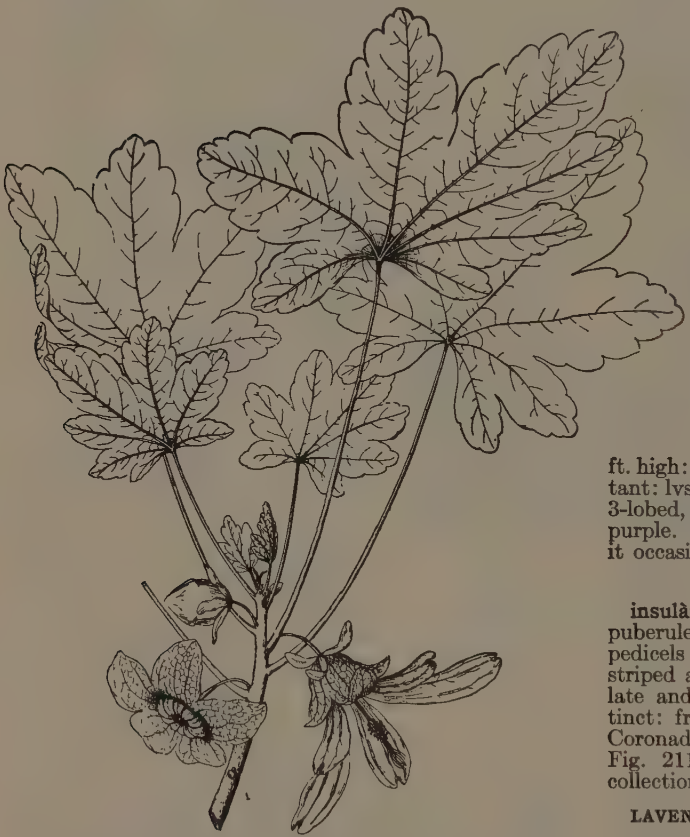
LAVÁNGA (from the Bengal name). Sometimes written *Luvunga. Rutàceæ,* tribe *Cítreæ.* Lavangalata. Climbing shrubs, distantly related to the orange.

Leaves alternate, trifolioliate, with long wingless petioles; lfts. with motile petiolules; spines axillary, strong, recurved: fls. in axillary clusters, 4–5-merous; stamens twice as many as the petals; anthers linear; ovary 3-, 4- or 5-celled with 2 superposed ovules in each cell: fr. oval or oblong, resinous within (without pulp vesicles) and having a thick oily lemon-like peel. —Several species are known, occurring in India, the Malayan Archipelago and Cochin-China. These plants should be intro. into the U. S. for trial as stocks for citrous frs., and for use in breeding experiments. The name is commonly spelled Luvunga, but appears as Lavanga in the original publication.

scándens, Buch.-Ham. (*Limònia scándens,* Roxbg.). Climbing shrubs with fragrant white fls. and yellowish resinous frs. the size of a pigeon's egg. This strong-growing scandent shrub occurs in India and the Malayan peninsula. WALTER T. SWINGLE.

LAVÀTERA (one of the Lavater family of Zurich, at the time of Tournefort). *Malvàceæ.* Flower-garden annuals and biennials, and some ornamental shrubs, the taller known as tree mallows.

Herbs, shrubs and trees, tomentose or hairy: lvs. angled or lobed, sometimes maple-like: fls. sometimes 2–4 in. across, variously colored, rarely yellow, solitary in the axils or borne in terminal racemes; column of stamens divided at the summit into an indefinite number of filaments; petals 5; ovaries few to many, united about an axis which is conical or umbrella-shaped at top; fl.-bractlets 3–6 or 9, joined into an involucre.—Species about 25, mostly in the Medit. region, but extending to the Canaries, Asia, Austral., and the islands off S. and Lower Calif.



2117. Lavatera insularis. (×½)

These plants are of the easiest culture, the first species being the commonest, and all propagated by seeds. There seem to be no double forms.

A. *Plant annual, herbaceous.*

triméstris, Linn. (*L. ròsea,* Medikus). Fig. 2116. Height 3–6 ft.: lvs. nearly glabrous, upper ones angled: fls. rosy, 4 in. across: receptacle or axis of the fr. expanded at the apex into a disk, inclosing the ovary. Medit. region. B.M. 109. Gn. 24, p. 89; 51, p. 212; 53:62; 61, p. 180; 65, p. 354. Gn. W. 23:363. Var. **álba,** Hort., has white fls. Var. **spléndens,** Hort., is an improved garden strain. Gn. 73, p. 314. G. 33:141.—This species is an excellent flower-garden subject, of the easiest cult., usually growing 2–3 ft. in height and blooming summer and autumn, with attractive rose-pink or red fls.

AA. *Plant biennial, woody at the base.*

arbòrea, Linn. With annual flowering branches, forming a shrub 3–10 ft. high or less: lvs. 5–9-lobed, softly downy on both sides, rarely nearly glabrous: fls. pale purple-red, about 2 in. across: receptacle small, marked with little pits, not exserted. Eu. Cult. in the form of var. **variegàta,** which has mottled lvs. Gn. 23, p. 114. G.Z. 28, p. 49. V. 8:99.

AAA. *Plant perennial, shrubby or even tree-like.*

B. *Fls. 1–4 in the axils, pedicelled.*

assurgentiflòra, Kellogg. Shrubby, 6–15 ft. high: lvs. glabrous or sparingly stellate-pubescent, 5–7-lobed, 3–6 in. wide: fls. purple; petals 1–1½ in. long, with long, narrow, glabrous claws, and a pair of dense, hairy tufts at the base: axis of the fr. low-conical, about as long as the carpels. S. Calif. Isls.—It makes a strong, round-headed shrub, with large red fls., and is one of the best plants to stand saline winds. Used extensively as a windbreak for vegetable-gardens about San Francisco, and is common in old yards throughout Calif., and has been suggested for forage; very resistant to drought. From seed it will reach 6 ft. or more and will bloom within a year.

BB. *Fls. solitary, sessile.*

Ólbia, Linn. Perennial, shrubby, about 6 ft. high: hairs of the st. pilose, somewhat clustered, distant: lvs. softly tomentose, lower ones 5-lobed, upper 3-lobed, highest oblong, scarcely divided: fls. reddish purple. S. Eu. G. 36:733.—Cult. in England, where it occasionally sows itself.

BBB. *Fls. solitary, stalked.*

insulàris, Wats. Fig. 2117. Low bush, cinerous-puberulent, with 7-lobed obtusely dentate lvs.: fls. on pedicels shorter than themselves, yellowish white striped and tipped with purple, the petals long-spatulate and emarginate; bractlets spatulate, almost distinct: fr. of about 10 carpels, in an enlarged calyx. Coronados Isls., near S. Calif. G.F. 9:165 (reduced in Fig. 2117).—Probably not cult. outside amateurs' collections in S. Calif.

WILHELM MILLER.
L. H. B.†

LAVENDER: *Lavandula.*

LAVENDER COTTON: *Santolina Chamæcyparissus.*

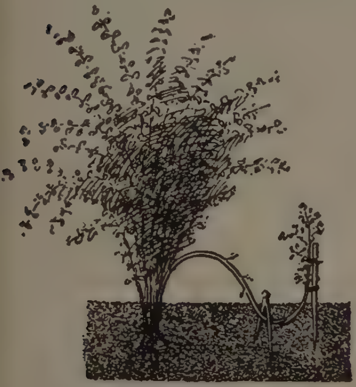
LAWN: *Landscape Gardening,* pp. 1816–1818.

LAWSÒNIA (John Lawson, who published, in 1709, an account of his travels in North Carolina; see page 1505). *Lythràceæ.* HENNA. Shrubs, grown in Florida and southern California for ornament.

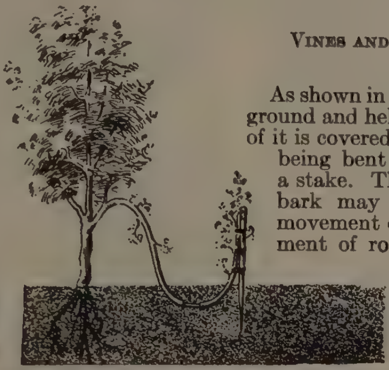
Sometimes becoming arborescent, 6–25 ft., glabrous, the branches more or less spinescent: lvs. opposite, lanceolate, attenuate into a petiole or a narrow base, entire, acute: fls. 4-merous, rather small, in terminal panicled cymes; calyx-tube very short or none, the lobes 4; petals 4, ovate, wrinkled, on the top of the calyx-tube; stamens usually 8, exserted, sometimes only 4 and sometimes 12; ovary 4-celled, with a long style and a capitate stigma: caps. globose, exserted beyond calyx.—One variable species as defined by Koehne (Engler's Pflanzenreich, hft. 17, 1903).

inérmis, Linn. A handsome shrub with many very fragrant fls. Var. *álba,* Hassk. (*L. álba,* Lam.) has white fls.; otherwise they are rose, an *L. rùbra* is listed, and var. *miniàta*, Hassk., is cinnabar-red. Widely cult. in tropical countries, but probably native in N. Afr., to W. and S. Asia; naturalized in W. Indies, where it is known as "mignonette." Its lvs. produce the henna or alhenna of the Arabs (cyprus of the ancients), a yellow dye which is used in Egypt and elsewhere by women to color their nails, and by men to dye their beards, and for other similar uses. It is also known in W. Indies as "Egyptian privet," and sometimes as "reseda." It is the camphire of the authorized version of the Bible.

L. H. B.



2118. A layer notched at the bottom.

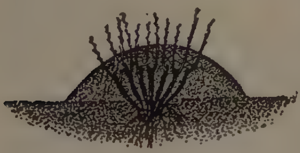


2119. A layer ringed or girdled at the bottom.

LAYERS, Propagation by. A layer is a stem that is made to take root while still attached to the parent plant. The whole subject of propagating plants by means of layers is known as *layerage;* the actual operation or practice is *layering.*

The tendency, under favorable conditions, to produce roots from the cambium zone of some part of the stem is manifested by many plants, especially in the tropics. It may be noticed in the species of ficus cultivated in the greenhouse, in epigæa and *Rhus Toxicodendron* in the woods, in tomato vines in the garden, in grape-canes lying on the ground, and frequently in young apple trees when the trunk becomes covered with earth to an unusual depth. With most such plants, rooting by detached parts is easily accomplished, and this being more convenient, layering is usually practised only with those plants that do not root readily from cuttings.

The mode of root-production is essentially the same whether the part is a layer or a cutting. The proper conditions as to moisture, temperature, food-supply, seem to stimulate the formation of one or more growing points in the cambium zone. The multiplying cells force their way through the bark, and if favorable soil contact is secured, supporting roots are soon developed. It is when the food supply is deficient or the cell action is so slow that the detached part will perish before supporting roots can be established, that rooting while the parts are still attached to the parent plant and nourished by it need be employed.



2120. Mound- or stool-layering.

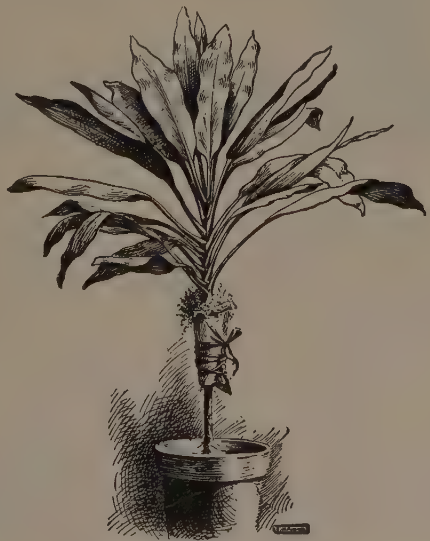
The different methods of layering are matters of detail adapted to the varying plants to be dealt with. Usually branches are chosen of rather young wood, which can easily be brought under the soil and which, when rooted, can be removed without damage to the old plant. The most favorable season is usually the spring or time of most rapid cell-growth. The methods of layering may be represented in the following diagram:

- TREES AND SHRUBS . .
  - *Bowed branch—*
    - Bark ruptured.
    - Bark ringed.
    - Tongue cut.
    - Tip layered.
  - *Mound- or stool-layer.*
  - *Potted or aërial layer.*
- VINES AND CANES . . .
  - *Simple layer.*
  - *Trench layer.*
  - *Serpentine layer.*

As shown in Fig. 2118, a suitable branch is bent to the ground and held in place by a forked pin, so that a part of it is covered with 2 or 3 inches of rich earth, the end being bent to an upright position and fastened to a stake. The bend and consequent rupture of the bark may be all that is needed to obstruct the movement of food-material and cause the development of roots at this point. If not, a tongue may be cut not deeper than one-third the thickness of the branch from below upwards and near a bud or node. In Fig. 2119 a layered branch is shown with a ring of bark removed, a good practice with thick hard-barked species.

For many low-branched shrubs, mound- or stool-layers are prepared (Fig. 2120), as follows: In the spring, head the bush back to a series of stubs, which will produce a large number of vigorous young shoots. By midsummer, in some cases, or the following spring, a mound of earth is thrown around the old stool and the base of the new shoots, and from these latter abundant rooting is secured, so that by the following autumn or spring they may be separated and set in nursery rows. Dwarf apple stocks, and English gooseberries, are propagated extensively by means of mound-layers.

When a branch cannot be brought to the ground, sometimes the earth is brought to the branch by clasping the halves of a broken or specially made pot around a tongued or girdled branch. The receptacle is filled with earth and sphagnum moss to retain the moisture; or the moss may be held in place by a cone of strong paper (Fig. 2121). It may be necessary to support the pot with a light stand of stakes. Where a moist atmosphere is retained, as in a conservatory, merely a ball of sphagnum bound around the branch with twine will serve an equally good purpose with less trouble. This kind of propagation is known as air-layering, Chinese layering or circumposition.



2121. Air-layering.

In the case of vines, a cane may be laid horizontally in a shallow trench, covering a few inches to induce rooting, and leaving a node or two exposed for growth, and so on to the end, as shown by Fig. 2122. After young shoots are well started from the uncovered buds, the earth may be filled in to the level of the ground line.

In Fig. 2123 is shown what is often called the serpentine layer, in which the cane is bent, parts being covered and the intervals left above the ground. It is held that by this means the tendency of the sap to flow to the extremity and there make the strongest growth, is overcome, and even rooting secured the whole length of the cane. This method is often used with quick-growing vines like clematis and wistaria, from which it is possible to secure a succession of layers from the annual growth in spring and early summer.

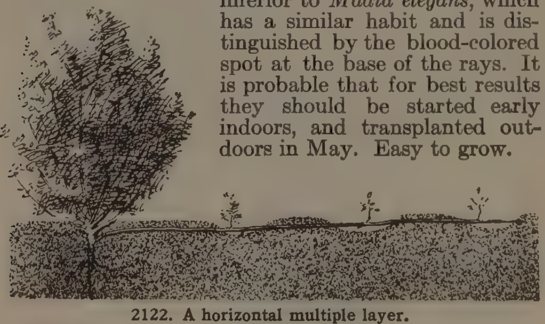
The "tips" of black raspberries are layers of a special kind. In this case, the cane bends over and takes root at its end, thereby providing a natural means of propagation. Many plants produce stolons, or shoots springing from the crown and having a strong tendency to take root at joints or tip; this attribute is sometimes indicated in the name of the plant, as *Cornus stolonifera*.

All of the foregoing operations are more readily successful in the more moist situations; more successful in the nearly saturated atmosphere of the southern states, for instance, than in the comparatively dry conditions of the prairie states.

S. C. Mason.

LÀYIA (Thomas Lay, naturalist in the Beechey voyage). *Compósitæ.* Annual herbs with yellow or white flowers in spring or early summer.

Leaves chiefly alternate, all entire or some, particularly the lower, pinnately toothed or lobed: fls. about 1–1½ in. across, and the rays distinctly 3-toothed; ray-fls. 8–20; disk-fls. fertile, their tubular corollas 5-toothed.—About 13 W. American species. The species described below are diffuse, much-branched and about a foot high. For general cult. they are probably inferior to *Madia elegans*, which has a similar habit and is distinguished by the blood-colored spot at the base of the rays. It is probable that for best results they should be started early indoors, and transplanted outdoors in May. Easy to grow.



2122. A horizontal multiple layer.

A. *Rays entirely white.*

glandulòsa, Hook & Arn. White Daisy. One-half to 2 ft. tall, the st. hispid, sometimes glandular: lvs. 1–1½ in. long, 2–3 lines broad, linear, the upper ones all entire: rays 8–13, white or sometimes tinged with rose. B.M. 6856. Brit. Col and Idaho to Mex.—Cultivated in California and very desirable on account of its pure white rays.

AA. *Rays yellow, sometimes tipped white.*

B. *Plants hairy.*

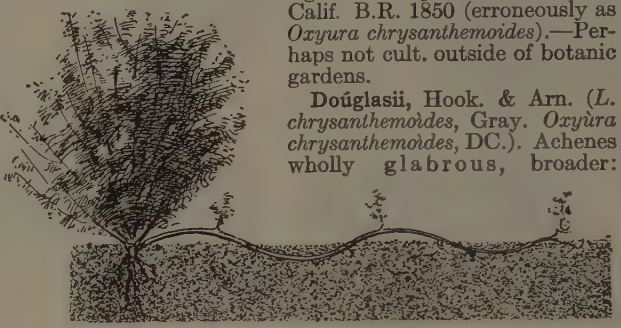
élegans, Torr. & Gray. Tidy Tips. All the upper lvs. entire: rays 10–12, yellow, rarely white-tipped; pappus white or whitish, its copious villous hairs much shorter than the awn-shaped bristles, which are long plumose below the middle. This and the next have a few small, scattered, stalked glands which are wanting from the last two. Calif. Gn. 31, p. 465. G. 30:567. G.W. 17: 464.—Perhaps the best of the genus. Var. **álba,** Hort., is a pure white form

platyglóssa, Gray. Tidy Tips. Some of the upper lvs. pinnatifid: rays light yellow, commonly white-tipped; pappus of stout, awn-like bristles which are upwardly scabrous. Calif. B.M. 3719.

BB. *Plants not hairy or at most minutely pubescent.*

Calliglóssa, Gray (*Calliglóssa Doúglasii,* Hook. & Arn.). Achenes villous-pubescent or partly glabrate: rays yellow, white-tipped; pappus of 10–18 very unequal and rigid awl-shaped awns. Central Calif. B.R. 1850 (erroneously as *Oxyura chrysanthemoides*).—Perhaps not cult. outside of botanic gardens.

Doúglasii, Hook. & Arn. (*L. chrysanthemoìdes,* Gray. *Oxyùra chrysanthemoìdes,* DC.). Achenes wholly glabrous, broader: pappus none. Fls. yellow, only the tips of the rays white. A confused species.



2123. Serpentine layering.

L. gaillardioìdes, Hook. & Arn. Branching rather freely, hispid, 8 in. or more high: heads rather large; rays orange-yellow. G.C. III. 32:61.

N. Taylor.†

LEAD PLANT: *Amorpha canescens.*

LEADWORT: *Plumbago.*

LEATHER FLOWER: *Clematis Viorna.* **L. Jacket:** *Eucalpytus punctata.* **L. Leaf:** *Chamædaphne.* **L. Wood:** *Dirca palustris;* also *Cyrilla.*

LEBIDIERÓPSIS (Greek; *like Lebidiera,* a related genus now included in Cleistanthus). *Euphorbiàceæ.* The genus contains but 1 species, a tree once catalogued in S. Fla., probaby not now in cult. in Amer. Lvs. alternate, simple, entire: fls. small, in axillary clusters; calyx of staminate fls. valvate; petals small; stamens 5, filaments united; ovules 2 in each of the 3 cells of the ovary: seeds globose, cotyledons thick and flat.

orbiculàris, Muell. Arg. (*Cleistánthus collìnus,* Benth.). Lvs. 1½–4 in. long, 1½–3 in. wide, leathery, broadly ovate or elliptic, tip rounded or retuse, glaucous beneath, 5–8 pairs of nerves: fls. silky, 3–6 in a cluster; petals fleshy, narrow: seeds 2 lines thick, chestnut-brown. India.—Variable in lf.-form and hairiness.

J. B. S. Norton.

LÈCYTHIS (Greek for an *oil-jar,* from the shape of frs.). *Lecythidàceæ.* One of a group of interesting Trop. American genera, comprising Couroupita, Grias, Japarandiba, Bertholletia. The species of Lecythis are shrubs or trees, one or two of which have been grown under glass abroad for their showy red fls. *L. Zabucajo,* Aubl., yields the excellent sapucaya nuts, resembling Brazil-nuts and superior to them. *L. Ollaria,* Linn., the monkey-pot, yields a regular urn-shaped fr. or box with a lid or cover. Lecythis is of perhaps 40 species, of the habit of Couroupita but fls. smaller, in Trop. S. Amer.: lvs. alternate, coriaceous, entire or serrate: fls. usually large, in panicles or racemes; calyx with a turbinate tube and 4 or 6 segms.; petals usually 6, sometimes 4, nearly equal; stamens many, united in a hood-shaped body with the fertile anthers beneath: fr. leathery or woody, odd, globose or cup-shaped or urn-shaped with an operculum; seeds few, often large. None of the species seems to be of horticultural importance within our range.

LEDENBÉRGIA (von Ladenberg, mispelled in making the name). *Phytolaccàceæ.* A twining subshrub from Trop. Amer., allied to Rivina, with ornamental foliage: lvs. simple, entire, alternate, slender-stalked, ovate or elliptic-ovate: fls. small and whitish, in long axillary peduncled racemes, on very slender pedicels, perfect; perianth 4-parted, the segms. linear-oblong or linear-obovate and obtuse, enlarging in fr.; stamens 12: fr. a small achene. The plant in cult. is *L. ròseo-ænèa*, Lem. (*L. purpùrea*, Hort.?), which is *Trichostigma peruvianum.* The single species of Ledenbergia is *L. seguierioides*, Klotzsch, of the Antilles and S. Amer., which is a slender-branched shrub with elliptic acuminate alternate lvs. and many small greenish fls. in long drooping very slender racemes. Apparently not in the trade.

LÈDUM (*ledon*, ancient Greek name of Cistus). *Ericàceæ.* LABRADOR TEA. Ornamental shrubs grown for their handsome white flowers and evergreen foliage.

Leaves alternate, short-petioled, entire: fls. rather small, ⅓–½in. across, long-pedicelled, in terminal, umbel-like racemes; calyx-lobes and petals 5, spreading; stamens 5–10: caps. nodding, 5-celled, separating from the base into 5 valves, with many minute seeds.—Four species in the arctic and cold regions of the northern hemisphere, all found in N. Amer. One of the few ericaceous genera with polypetalous fls. The lvs. contain a volatile oil, with narcotic properties; the lvs. of *L. grœnlandicum* are said to have been used during the War of Independence as a substitute for tea, hence the name "Labrador tea."

These plants are low, sometimes procumbent, shrubs with evergreen narrow leaves fragrant when bruised, and with handsome white flowers appearing in early summer. They are all hardy North, and well adapted for borders of evergreen shrubberies or for planting in swampy situations. They thrive as well in sunny as in partly shaded situations, and prefer a moist, sandy and peaty soil. Transplanting is easy, if the plants are moved with a sufficient ball of earth. Propagation is by seeds sown in spring in sandy peat and treated like those of azalea and rhododendron, the young plants growing but slowly; increased also by layers and division.

palústre, Linn. WILD ROSEMARY. One to 2 ft. high: lvs. linear or linear-oblong, revolute at the margin, dark green and somewhat rugose above, densely ferrugineous-tomentose beneath like the young branches, ½–1½ in. long: stamens usually 10: caps. ovate. May, June. Northern hemisphere, in N. Amer., from Newfoundland to Alaska. L.B.C. 6:560. Var. **dilatàtum,** Gray. Lvs. broader, sometimes glabrescent and glaucous below: caps. more oblong. Amurland, Japan. Var. **decúmbens,** Ait. (*L. decúmbens*, Lodd.). With procumbent sts. and shorter lvs. N. E. N. Amer. B.B. (ed. 2) 2:677.

grœnlándicum, Oeder (*L. latifòlium*, Ait). LABRADOR TEA. One to 3 ft., similar to the former, but lvs. broader, ovate to narrow-oblong, 1–2 in. long, tomentum beneath often rather pale at first: stamens 5–7: caps. oblong. May, June. Canada to Brit. Col., south to Pa. and Wis. L.B.C. 6:534 and 11:1049 (as *L. canadense*). J.H. III. 31:20 (as *L. palustre*). Gn. 34, p. 31. M.D.G. 1906:74 (habit). G. 35:349.

L. buxifòlium, Berg=Leiophyllum buxifolium.—*L. columbiànum*, Piper. To 3 ft.: lvs. glabrous and glandular below, revolute: stamens 5–7: caps. oblong, acutish. Wash., Ore.—*L. glandulòsum*, Nutt. Shrub, to 6 ft.: lvs. oblong or oval, glabrous, glaucous and glandular beneath, not revolute: stamens 10: caps. oval, obtuse. July, Aug. Brit. Col. to Calif. B.M. 7610.—*L. Lỳonii*, listed abroad, is undeterminable. It is described as "a lovely shrub for rock-garden, very pretty in bud."

ALFRED REHDER.

LEÈA (James Lee, Scotch nurseryman, 1715–1795). *Vitàceæ.* Tropical small trees or shrubs, some of which are cultivated as young plants in warm conservatories for their colored foliage and stately habit.

Leaves alternate, 1–3 times pinnate or simple, the petiole dilated at base; lfts. entire or serrate; tendrils none: fls. small or large, red, yellow or green, in cymes opposite the lvs.; calyx 5-toothed; petals 5, connate at the base and joined with the tube of stamens; ovary 3–6-celled; cells 1-ovuled: fr. a berry, mostly succulent, nearly globose but flattened at the top.—Species about 65, in tropics of Afr., Asia, Austral. and Pacific. Vitis differs in having the climbing habit, ovary 2-celled; cells 2-ovuled. The first species mentioned seems to be valued particularly for its fls.: the others are foliage plants which are presumably distinct horticulturally, but two of them may not be good botanical species, and cannot be distinguished without a knowledge of the fls.

Leeas are tropical house plants. *L. amabilis* has beautiful silvery vine-like foliage. It makes a handsome plant for pillar-posts, and does exceedingly well planted out; but it should be given a season of rest in winter by a partial drying out, when it will lose most, if not all, its foliage. This practice should be followed in any case. It may also be grown as a trained specimen in pots. Peaty soil is often recommended, but good light loam, with plenty of drainage, does equally well. (T. D. Hatfield.)

A. *Foliage green.*

coccínea, Planch. Lvs. 3-pinnate; lfts. 5 on each main division of the lf., oblong-lanceolate, dentate, margin recurved: fls. 60 or more in a trichotomous, flat-topped cluster about 3 in. across, scarlet in bud, the 5 spreading lobes of the corolla pink above; stamens yellow, exserted, each fl. about ½in. across. Burma. B.M. 5299.—It begins to flower when only a foot high, but the main stalk of the clusters is only an inch or so long.

AA. *Foliage colored or variegated.*

B. *Lvs. marked bright red; veins white.*

Micholítzii, Sander. Intro. by Sander & Co., 1899, from New Guinea: st. slender: lvs. pinnate, sometimes gigantic, arching; lfts. deeply serrate and undulate, rich green strongly marked with bright red and with white veins on the young lvs.

amábilis, Veitch. Lvs. pinnate; lfts. 5 or 7, lanceolate, acuminate, serrate, upper surface velvety, deep bronzy green, with a broad white stripe; veins white at the bases; young lvs. pale pinkish brown. Borneo. G.C. II. 17:493. Gn. 21, p. 352. J.H. III. 43:253. G.Z. 27, p. 145. Var. **spléndens,** Lind., is marked with bright red and has a red st.; very attractive. I.H. 31:518.

BB. *Lvs. flushed bronze; veins rosy.*

sambùcina, Willd. (*L. Rœhrsiàna*, Sander.). Lvs. pinnate or 3-pinnate, very large (often 4 ft. long); lfts. 6½ in. long, 2½ in. wide, oblong, cordate at the base, acuminate, coarsely crenate. India, Malaya, Philippines, Trop. Austral. A very variable species. The above synonymy is the judgment of M. T. Masters in G.C. III. 23:245. F.E. 10:554. A.F. 13:1284. Gng. 6:278. A.G. 21:97.

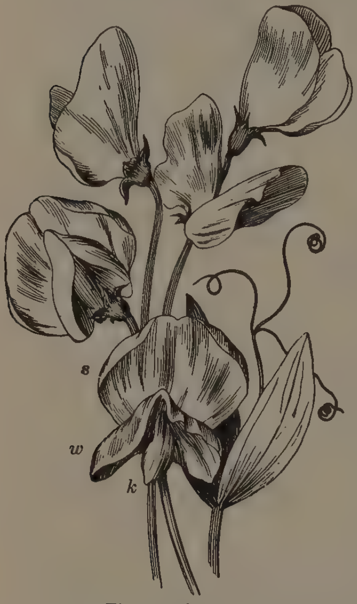
Other leeas may be expected in the choice collections of amateurs, but these plants appear to be little known in the trade. *L. mácropus*, Laut. & Schumann, "with broad lfts.," is a recent introduction.

WILHELM MILLER.

LEEK (*Allium Porrum*), a flat-leaved, bulbous, hardy biennial, is probably a native of the Mediterranean region, where, particularly in Egypt, it has been used for culinary and medicinal purposes since prehistoric time. All parts of the plant possess an offensive pungent odor and acrid taste due to an essential oil also characteristic of its close relative, the onion. In medicine, the bulb, like the onion, is used as a renal stimulant. The blanched stems and leaves are much employed in continental cookery as a flavoring for soups, stews, and so on, boiled and served like asparagus, and in the raw state.

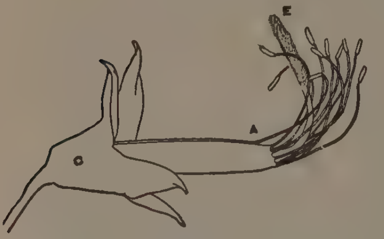
Except in the larger cities and among our foreign population, the leek is little used in America.

Leek, though of the onion family, is differently treated and used. The object in its cultivation is to develop the leaves in such a manner that they become numerous; the flower-stem does not appear before the second year, hence the necessity of growing it to full size the first year.



2124. Flowers of sweet pea, to show structure of a leguminous flower. Banner, standard or vexillum at *s*; wings at *w*; keel at *k*.

Sow the seed in March in a seed-bed (with slight bottom heat), in drills 2 or 3 inches apart; when large enough, thin out to stand 1 inch apart in the row, as they may attain the thickness of a fair-sized straw. In May or early June the seedlings are transplanted in the open ground; they are then cut half-way down and should also be set deep, so they will begin blanching when they attain a fair size. The soil best suited is a rich, moist, light loam; prior to the transplanting it should be well prepared with well-rotted stable manure, if possible. The plants are generally set in drills 12 to 15 inches apart, and 6 to 9 inches apart in the drills. Shortening both roots and stems is often advised. As the plants grow, the soil should be drawn loosely around the stems and lower leaves to insure blanching. They should be well cultivated, and when growing freely should be earthed up slightly with the hand-cultivator or hand-hoe. Some of the successful gardeners still cultivate them on the celery-trenching system; by this means they can be watered more thoroughly and will attain a much larger size; also can be conveniently left in the trench with slight protection, and taken therefrom for winter use. Care must be taken not to cover too early, as they decay easily, beginning at the end of the foliage; this destroys the appearance. The hardier kinds used for this purpose will blanch yellow down to the so-called stem, which is white to the root. Leeks planted out in May are ready for use in September; the sowings can be made earlier and later to suit the time of maturing, and can be sown in August and September in coldframes and wintered over with slight protection, then transplanted to the open ground in April. The varieties best known to American gardeners are London Flag, Large Musselburgh or Scotch Flag, Giant Carentan, and Large Rouen.

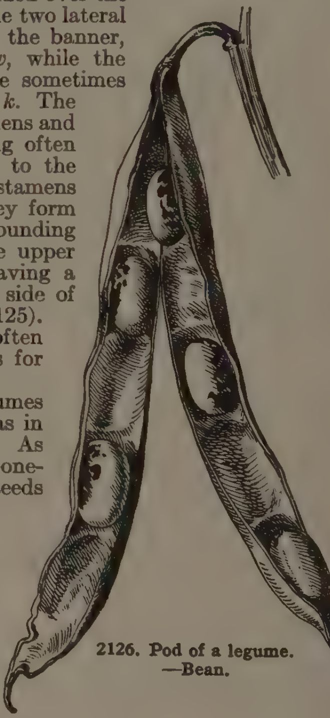


2125. Essential organs of a sweet pea flower. Calyx at *c*; tenth stamen at *a*; stigma at *e*.

When blanched leeks are not desired, the plants may be cultivated like onions; indeed, except for earthing up, the cultural methods employed for these two crops are identical. Leeks are marketed in bunches like young onions and, for winter use, are stored like celery. As a second crop to follow early cabbage, spinach, and the like, they are in general favor with market-gardeners. In soups and stews the rank odor disappears, leaving a mild and agreeable flavor. M. G. Kains and J. Otto Thilow.

LEGUMES. The popular name given to the important group of plants included in the general Order Leguminosæ comprises the herbs, shrubs, vines, and trees of the mimosa family (Mimosaceæ), the senna family (Cæsalpiniaceæ), the krameria family (Krameriaceæ), and the pea family (Fabaceæ; also called Papilionaceæ or Phaseolaceæ). In all, more than 7,000 species of plants are represented here, chiefly herbaceous in character; the arboreal forms occur in the temperate zones and are very frequent in the tropics. Many species are of unusual agricultural importance, both for forage, as cover-crops and green manure, and also for furnishing food for man. Among these may be noted alfalfa (*Medicago sativa*), beans (Phaseolus sp.), clover, (Trifolium sp.), vetch (Vicia sp.), and peas (Pisum sp.).

Most of the native species of legumes, and all those cultivated as farm crops, belong to the Fabaceæ or pea family. In these species the flower is of the pea type (Fig. 2124). The upper larger petal, called the banner, *s*, is exterior and folded over the others in the bud. The two lateral ones, situated below the banner, are the wings, *w*, *w*, while the lower pair, which are sometimes united, form the keel, *k*. The keel incloses the stamens and pistil, the latter being often bent at right angles to the ovary, or coiled. The stamens are either free or they form a tubular sheath surrounding the ovary. Often the upper one alone is free, leaving a slit along the upper side of the sheath (Fig. 2125). These flowers are often dependent on insects for pollination.



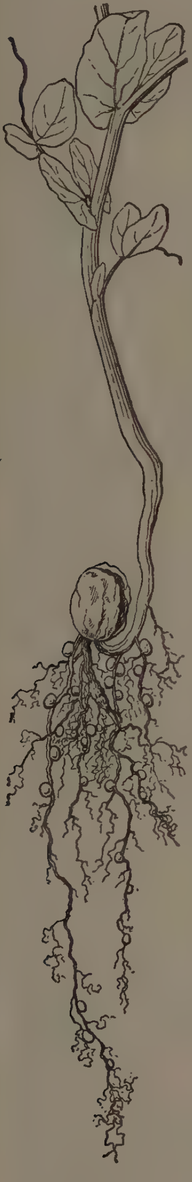
2126. Pod of a legume. —Bean.

The fruit of the legumes is a pod or legume, as in the bean (Fig. 2126). As a rule, the pods are one-loculed, and have the seeds arranged in rows. In some tribes they become several-celled by partitions which arise between the seeds. These pods become constricted at the partitions, and at maturity separate into short joints (see Fig. 1244, Vol. II). The valves of the pods are generally papery or leathery, and open at maturity, often by a sudden snapping of the valves, which scatters the seeds. In other tribes, however, the pods are indehiscent, or do not split at maturity (Fig. 2128).

The use of leguminous crops for soil improvement has long been recognized by good farmers as desirable. Aside from the general benefits of crop-rotation, the actual soil-enrichment is due largely to an accumulation of available nitrogen, and this gain in nitrogen is caused by the presence of minute soil-bacteria which possess the power of growing on the roots of the legumes, and then utilizing or "fixing" the free nitrogen of the air and converting it into food for succeeding crops.

In view of these facts, it is evident that for the most successful growth of alfalfa, clover, vetch, and other legume crops, the proper organisms should be abundantly present in the soil. Certain localities are so supplied, as, for example, southern regions, which contain the cowpea organism naturally, and sections of the Middle West, which usually are inoculated with alfalfa organisms. Introducing new kinds of leguminous crops into a locality requires the introduction also of the proper bacteria for the legume selected, and this is best accomplished by either of the following methods of artificial inoculation:

When a field is known to be well inoculated for a certain legume crop—for example, alfalfa—as indicated by the presence of numerous nodules upon the roots of alfalfa plants growing therein, such soil is very desirable for the inoculation of other fields on the same farm or on nearby farms upon which alfalfa is to be sown for the first time. Two hundred pounds or more of sifted field-soil are sufficient for an acre. Transferring field-soil from any considerable distance is, however, expensive and subject to the danger of introducing troublesome weeds, insects, and plant diseases.



2127. Nodules on the roots of a young plant of garden pea.

Another method is that of seed-inoculation by means of pure cultures. For many years the United States Department of Agriculture has cultivated and distributed liquid pure cultures of the bacteria beneficial to legume crops, and commercial organizations have produced and sold various types of cultures with more or less successful results. The seeds to be treated are placed in a clean bucket, pail, or tub and a pure culture of these beneficial bacteria is applied a little at a time, thoroughly stirring the seeds in order to form a thin, moist coating of the culture on every seed.

A comparison of the nitrogen-fixing nodules found upon the roots of different plants is interesting. The nodules are in reality roots or rootlets which, because of the presence of the nitrogen-fixing bacteria within their cells, have developed abnormally to form the characteristic swollen root tubercles or nitrogen-gathering nodules instead of the ordinary form of root (Fig. 2127). It is to be expected, as each kind of plant has a slightly different root-development, that the root-nodules will develop in a correspondingly typical manner. In fact, the nitrogen-fixing root-nodule of any kind of plant is almost as definite and characteristic for that plant as the shape of the leaves or the arrangement of the leaves on the stem. Karl F. Kellerman.

LEIOCHÌLUS: *Oncidium.*

LEIOPHÝLLUM (from *leios,* smooth and *phyllon;* referring to the smooth foliage). Syn., *Déndrium, Ammýrsine. Ericàceæ.* Sand Myrtle. Ornamental shrubs grown for their handsome evergreen foliage and the profusely produced small white flowers, although not much grown.

Densely branched shrubs, low and sometimes procumbent: lvs. opposite or alternate, crowded, small, short-petioled, entire: fls. in terminal, umbelliform corymbs; sepals and petals 5; stamens 10; anther-cells opening lengthwise; disk 10-lobed: fr. a 2–5-celled dehiscent many-seeded caps.—One species in E. N. Amer. from N. J. to Fla.; allied to Ledum, but the anther-cells opening lengthwise.

2128. An indehiscent or slowly dehiscent leguminous pod—Daubentonia.

The sand myrtles resemble in appearance somewhat the dwarf box and are quite handsome when studded late in spring with the numerous umbels of small white or pinkish flowers. They are hardy or nearly hardy North and well adapted for borders of evergreen shrubberies and also for rockeries. They thrive best in a peaty or very sandy, loamy soil and as well in a sunny as in a partly shaded position. Propagated by seeds sown in pans and placed in a cool frame or by layers put down in fall.

buxifòlium, Ell. (*Lèdum buxifòlium,* Berg. *Déndrium buxifòlium,* Desv.). Fig. 2129. Dense, leafy bush, to 3 ft. high: lvs. short-petioled, thick, oval or obovate, ⅕–⅓in. long: fls. white, pinkish outside, about ⅕in. across, on slender pedicels; petals elliptic, almost twice as long as sepals; stamens usually twice as long as petals: caps. about thrice as long as sepals. April–June. Pine-barrens and mountains, N. J. to Fla. B.M. 6752. Gn. 42, p. 559. B.R. 531. L.B.C. 1:52 (as Ledum). Var. **Hùgeri,** Schneid. (*Déndrium Hùgeri,* Small). Lvs. alternate, ⅓–½in. long: stamens about as long as petals: caps. about twice as long as sepals. High mountains of N. C. Var. **prostràtum,** Gray (*Déndrium prostràtum,* Small). Forming dense depressed tufts: lvs. usually oval, and deep green, very small, mostly opposite. High mountains of N. C. and Tenn. Alfred Rehder.

LEITNÈRIA (after Leitner, a German naturalist, killed in Fla. during the Seminole war). *Leitneriàceæ.* Cork Wood. A small tree or shrub, the only representative of the family which is most nearly related to the Myricaceæ and Salicaceæ; sparingly branched, the sts. swollen at the base, spreading by suckers: lvs. alternate, entire, rather large, without stipules: fls. diœcious in axillary catkins before the lvs.; staminate

2129. Leiophyllum buxifolium. (×⅓)

fls. without perianth, with 3–12 stamens; pistillate consisting of a short-stalked pubescent ovary with small gland-fringed scales at the base; style slender: fr. an oblong pointed compressed, 1-seeded drupe.—One species in Fla. and Texas to S. Mo. The exceedingly light wood is occasionally used for the floats of fishing-nets. Hardy as far north as Mass.; it grows best in peaty, humid or swampy soil. Prop. readily by suckers which are freely produced in established plants.

L. floridàna, Chapm. Occasionally to 20 ft.: lvs. elliptic-lanceolate to lanceolate, acute or acuminate, pubescent below, 4–6 in. long: staminate catkins 1–1¼ in. long; pistillate smaller and slenderer: frs. 1–4, ¾in. long. S. S. 7:330. H.I. 11:1044. Rep. Mo. Bot. Gard. 6:30–44.—The plant has no claim to ornamental qualities, but is botanically interesting.

Alfred Rehder.

LEMAIREOCÈREUS (Lemaire's Cereus). *Cactàceæ.* Usually large trees or shrubs (one species prostrate).

Stems and branches strongly ribbed and with numerous stout spines: fls. diurnal, medium-sized: fr. covered with clusters of spines (finally falling off as the fr. ripens), edible.—Species 13. This is one of the most important genera of the Cereus group. Some, and perhaps all, species are of great economic value; some are widely planted in the tropics for their delicious fr. Some 8 species are in cult.

A. *Plants prostrate: fls. yellow.*

erùca, Brit. & Rose (*Cèreus erùca,* Brandegee). Stout, usually simple sts. prostrate, radiating from a center, dying at one end and advancing at the other, rooting on the under surface, 3–7 in. diam., densely armed with spines: fls. 4–5 in. long, with a slender tube, reported to be yellow: fr. globular, 2 in. diam., somewhat spiny. Common on the sandy plains of S. Low. Calif.—Of very peculiar habit, suggesting large caterpillars creeping along over the ground. This is especially noticed from the way they pass over obstructions or the bodies of other individuals. First the head or growing end is raised up over the object and passes down on the other side; then, by the dying back at the rear, the plant finally seems to have actually passed over the obstruction. This cactus is usually planted wrong in collections since most gardeners insist on placing it erect in a pot; but as it is constantly dying at base, it must sooner or later die. It ought to be laid flat at one end of a long box and allowed to creep toward the other end. There seems to be no record of this species having flowered in cult.

AA. *Plants usually tall and erect.*

B. *Areoles with brown wool, more or less glandular.*

C. *Ribs 12–15.*

Thúrberi, Brit. & Rose (*Cèreus Thúrberi,* Engelm.). Several sts. arising from the same root, becoming 10–15 ft. high; ribs 13–16, very slightly prominent: spines 7–16, slender and rigid: fls. greenish white: fr. globose, 1–3 in. diam. S. W. Ariz. southward throughout Low. Calif., and to Sinaloa.

CC. *Ribs 6–8.*

queretarénsis, Brit. & Rose (*Cèreus queretarénsis,* Web.). Arborescent, with a trunk about 3 ft. high by about 14 in. diam.: the much-branched crown has a diam. of 12–16 ft., the total height of a plant being about 20 ft.: branches dark green, in young growth frequently of a peculiar violet-brown; ribs 6–7, separated by sharp grooves, which later become much flattened, and the st. consequently more cylindrical; areoles depressed, dark brown; radial spines 6–9, the lower ones longest, about 1¼ in. long; centrals 4 (often but 2), reaching 1½ in.: fls. numerous from the upper part of the branches, about 4–5 in. long: fr. yellow to red, about 2 in. long, covered with dark yellow to brown spines, about 1 in. long, and bulbose at the base. Mex.

BB. *Areoles with gray wool, not at all glandular.*

C. *The areoles of the ovary and fl.-tube bearing long flat bristles along with the spines.*

stellàtus, Brit. & Rose (*Cèreus stellàtus,* Pfeiff.). Stout, with few upright branches, 10–15 ft. high: ribs 7–15: areoles ½–1 in. apart; radial spines 8–10; centrals 3–5: fls. from near the ends of the branches, about 2 in. long, light pink: fr. globular, 1½ in. diam., covered with clusters of deciduous spines, edible.—Sold in markets of S. Mex. Rare in collections; often confused with *Rathbunia sonorensis* and *L. Treleasei.*

CC. *The areoles of the ovary and fl.-tube not bearing long bristles.*

D. *Fls. long and slender.*

gummòsus, Brit. & Rose (*Cèreus Cuméngei,* Web. *C. gummòsus,* Engelm. *C. gummòsus,* Hort.). More or less branched, at first erect, then clambering or with some of the branches procumbent: ribs 7–9: spines rigid, 15 or 20: fls. purple, 4–5 in. long: fr. spiny, scarlet, slightly acid, edible. Common in Low. Calif.—This species does not grow easily in hothouses nor does it flower readily. It is a very important fr. to the poor of Low. Calif.

DD. *Fls. rather short.*

E. *Areoles very close together, often running together.*

Dumortièri, Brit. & Rose (*Cèreus Dumortièri,* Salm-Dyck). Often large tree with a trunk 2 ft. diam. and hundreds of upright branches: branches strongly 6-angled: areoles closely set; spines numerous, needle-like, the longer ones 1½ in. long: fls. small for the genus, 2 in. or less long, white. Cent. Mex.—Usually only small plants seen in cult.

EE. *Areoles more distant.*

gríseus, Brit. & Rose (*Cèreus gríseus,* Haw. *C. ebúrneus,* Salm-Dyck). Tall tree, 25 ft. or more high, more or less branched: ribs 7–12, broad: spines 10–15: fls. purplish: fr. globular, covered with deciduous clusters of spines, edible.—Commonly cult. in Trop. Amer. for its frs. It is especially highly prized in Mex.

Wéberi, Brit. & Rose (*Cèreus Wéberi,* Coulter. *Cèreus candelàbrum,* Web.). Trees, 30 ft. or more high, with a regular candelabra form of branching, containing hundreds of erect branches: spines stout, 10 or more on a cluster: fls. lateral, white, about 5 in. long: fr. unknown.—This species, although not the tallest, is probably the largest in the whole cactus family. It is found in the hot valleys of S. Mex. where it literally forms forests. The fr. is not well known and the relationship is still uncertain.

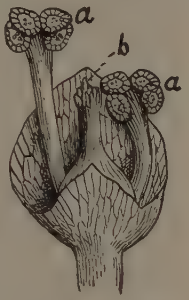
J. N. Rose.

LEMBÓTROPIS NÍGRICANS: *Cytisus nigricans.*

LÉMNA (old Greek name, probably referring to the swampy habitat). *Lemnàceæ.* Duckweed. Duck's-Meat. Minute floating plants, like fragments of green, often found in standing pools and sometimes introduced into aquaria and lawn basins.

The Lemnaceæ comprises the minutest of flowering plants, some 30 species in 4 genera: Lemna, Spirodela, Wolffia, Wolffiella. They are widely distributed in temperate, subtropical and tropical regions. They often cover the water of

2130. Duckweeds, Lemna minor. (Much enlarged) ponds with a mantle of green. The lemnas and spirodelas are most useful because larger and more conspicuous than the wolffias. They are easily gathered for schoolroom and home aquaria, and may be procured from specialists in aquatics and native plants. Ducks and some fish eat these plants. One of the common duckweeds is shown 6 times its natural size in Fig. 2130. The lemnas are without any distinct sts., a whole plant commonly consisting of 1 miniature lf. and 1 unbranched root which has no vascular tissue. These lvs. are called fronds by the botanist. The plants grow separately, or cohere by their edges in 2's or 3's, and multiply by similar fronds, which grow out of the edges of the old ones something like buds. The fls. are minute and appear on the edge of the frond. They consist apparently of a pistil and 2 stamens which are inclosed in a sheath, which botanists have determined is a spathe by reason of the place where it is borne and by homology with related plants. Botanists now consider the 2 stamens as 2 fls. and the pistil a third fl. *L. minor* is said to flower more frequently than any other northern species. Details of its fl. are shown in Fig. 2131, where there seem to be 4 anthers, but there are only 2, each bearing 2 locules. Duckweeds are perennial plants. In the autumn they fall to the bottom of the ditch or pond, but rise again in the spring, and increase in size. The allied genus Wolffia contains the smallest flowering plants. There are about 10 or a dozen species of duckweeds, widely scattered. *L. polyrhiza* is now known as *Spirodela polyrhiza*, but Spirodela is considered by Bentham and Hooker a subgenus of Lemna. The common duckweed occasionally infests the small lily ponds (artificial ones), where it is a pest. The simple remedy is to flush the pond and see that common goldfish or carp are in sufficient numbers to clear off the remainder.



2131. Floral details of Lemna minor. *aa*, **stamens;** *b*, **pistil.** (Enlarged)

A. *Veins 7–11: roots several* (*Spirodela.*)

S. polyrhìza, Schl. Fronds broadly obovate or orbicular, attaining 3 or 4 lines diam., palmately nerved. Common in U. S.

AA. *Veins 1–5: root solitary.* (*Lemna.*)

B. *Fronds oblong, 6 lines long, 3 lines wide.*

L. trisúlca, Linn. Fronds thin, narrow and minutely toothed at one end, thicker and stalk-like at the other, usually with 2 young ones growing from opposite sides near the base. V. 3:200.—Common in U. S.

BB. *Fronds broadly ovate or orbicular, 2 lines long.*

L. mìnor, Linn. Figs. 2130, 2131. Fronds usually cohering in 3's or 4's, rather thick, not minutely toothed, 1–2½ lines long. V. 3:200.

Other species of Lemna are native in N. Amer. Of Wolffia there are also a few speces and of Wolffiella one. The wolffias are seldom collected for lawn ponds.

WILHELM MILLER.

LEMON (*Citrus Limonia*). Prior to 1894, the culture of the lemon in Florida was an industry of considerable importance. An annual output of 140,000 boxes had been reached, but the cold of 1894–1895 injured the trees and marked the beginning of the end of commercial lemon-production in the state for the time at least. Another contributing cause to the extinction of the industry was the development of anthracnose, a fungous disease causing brown spots on the fruit, particularly during curing and after shipment. The nature and control of this disease was not then understood. By 1901–1902 the crop had fallen to only a little over 1,000 boxes.

Since 1894, the citrous industry of Florida has moved southward. In consequence, regions have been opened up, which because of their more favorable location are very free from the blighting effects of cold. There is now a very noticeable awakening of interest in lemon-culture and it would not be surprising if the next ten to twenty years would see the industry once more established in the state. The outlook is further improved by the great advancement made in methods of orchard-heating and the control of the disease above mentioned.

Great care must needs be exercised in the selection of locations for growing lemons. The trees respond readily to increased temperatures and hence are too often in poor condition to withstand the low temperatures which often follow. Particular attention must be given to air-drainage and water-protection. Plantings of some size have been made in the last two or three years and still larger ones are contemplated.

The favorite variety and practically the only one planted is Villa Franca. It has proved to be materially hardier than other varieties such as Genoa and Eureka. The Rough lemon, a variety of uncertain relationship, grows as a wild or semi-wild tree in southern parts of Florida. Occasionally the fruit finds its way into the markets of the state. Its principal use is to furnish seed to grow seedlings on which to propagate different citrous fruits. Everbearing is grown here and there as a home fruit. Ponderosa, a large-fruited variety, is grown as a yard tree. When filled with fruit, the tree is very ornamental and the fruit is valuable for home use. This great fruit may be mistaken for a grapefruit (see *Pomelo*).

Lemon trees in Florida, are grown almost entirely on Sour orange and Rough lemon stocks, choice between these two being governed by the soil type and moisture conditions. It is best that the stocks be budded some distance above the ground. In northern Florida, Villa Franca is sometimes grown on *Poncirus trifoliata* stock and fruit is often secured.

Plantings are usually spaced 20 to 25 feet apart each way and the general care and cultivation is much the same as for other citrous fruits. In general, the plan pursued is to cultivate frequently during the usually dry spring season, March to June, after which a cover-crop of beggarweed, native grasses or cowpeas is given possession of the ground. By the middle of November, this cover-crop should be incorporated with the soil, either by shallow plowing or by cutting it in with a disc-harrow. It has been frequently demonstrated that injury to trees from cold is much less severe if all vegetation is cut into the soil, than if the ground is covered with grass and weeds.

Pruning requires careful attention to keep the trees low and compact. Lemons are very prone to produce long bare branches without fruiting twigs. They must be headed in to cause the development of fruiting spurs well in toward the center of the tree.

Protection of the fruit and trees must be provided. Up to this time the Scheu oil-heater is the best heating device that has been brought forward for this work. The temperature must not be allowed to go below 29° F. for any length of time if there is fruit on the trees. With these heaters there is no question but that the trees can be protected against cold in the southern parts of the state.

H. HAROLD HUME.

The lemon in California.

In general, the culture of lemons in California is similar to that of oranges (which see). Especially is this true in regard to soil requirements, propagation, irrigation, fertilization, and the like. The picking and handling of the fruit and pruning of the trees, however, differ radically from that of the orange.

The commercial lemon areas of California are situated near the coast, chiefly in the counties of San Diego, Orange, Los Angeles, Ventura and Santa Barbara, and in the western corner of San Bernardino. In this region the cool, moist summer climate causes the trees to bear a larger proportion of high-priced summer fruit. In the hot interior valleys some lemons are produced also; but while the trees will grow just as well under desert conditions, the fruit tends to mature mostly in the winter when the price is low. The fruit itself under such conditions is shorter-lived and will not keep so long nor ship so well as that produced near the coast.

Lemons are picked from ten to twelve times a year, each lemon being removed from the tree when it has reached a certain size, namely 2¼ inches in diameter. Each picker carries an iron ring of the above diameter and removes every fruit which will not pass through it, regardless of whether the lemon is ripe and yellow or perfectly green. Great care is taken to avoid the slightest abrasion of the skin. The stems are clipped off even with the "button," and the fruit is handled only in gloved hands and canvas picking-bags. The largest pickings are ready in the winter from December 1 to March 1, and as this is the time when the price of lemons is low, it is necessary to defer picking the main crop till March and April and to store an immense amount of fruit, holding it until the high prices of summer prevail. Sometimes seventy-five or one hundred carloads of lemons are stored in one house and held for three to six months. The smallest pickings come in the summer from June 1 to October 1, at a time when the price is the highest. It is necessary, therefore, to subject the green lemons to such an artificial treatment as will result in a good color in the shortest time possible. Thus the lemon-grower has two problems: one is to be able to retard respiration and the ripening process as much as possible and the other to accelerate these same processes.

For the process of spring storage, large houses are provided which are so constructed as to admit of perfect control of ventilation. On the storage-floor, there are a number of suspended canvas tents, each tent accommodating one carload of fruit. When the fruit is brought from the orchard, it is washed in a solution of one-fiftieth of 1 per cent of copper sulfate in water and piled loosely in boxes which are stacked under the tents. During moist, foggy weather the tents are raised and free circulation of air permitted. Should a dry, hot wind from the desert prevail, the tents are kept closed as tightly as possible in order to retard evaporation.

Lemons picked in September, however, after being run through the copper sulfate solution, are removed to a small fireproof building known as a sweat-house. The sweat-house usually has several rooms, each room accommodating one carload of fruit. The fruit is stacked in these rooms in the picking-boxes, the greenest and most immature in the rear and the lightest-colored fruit next the door. The room is then closed tightly and several kerosene stoves are burned in a basement below. Pans of water are kept on the stoves and the gases arising pass through cracks in the floor into the fruit-room. These gases consist of a mixture of carbon dioxide, carbon monoxide and water vapor. The temperature of the room is held as near 90° as possible and is regulated by the number of burners under the room. Great care is taken to keep the atmosphere saturated with moisture. Lemons are artificially colored in this manner in three to six days, depending on the depth of the green color in the rind.

The curing process causes the lemons to shrink in size slightly and the rind becomes thinner, more pliable, with a texture and general finish greatly desired by the market. During the whole process of picking and curing lemons they are handled very much more carefully than oranges. The grading and sizing is done almost entirely by hand, the washing-machine being the only bit of machinery through which lemons are passed.

For many years the lemon business in California did not flourish. Until fifteen years ago, California lemons had a very bad reputation for decay in the eastern markets, and perhaps justly. California growers did not possess the knowledge and the skill necessary for successful handling. One of the most serious troubles of those days was the brown-rot, which not only destroyed a third or more of the lemons on each tree in the orchard, but continued its ravages in the storage-house. The nature of this and many of the other troubles is now well understood and control methods systematized. The business has been readjusted to conditions until the old bad reputation has been lived down and by 1912 California lemons were selling steadily in the New York City auction at a premium over the European product.

On account of the peculiar troubles to which the lemon is susceptible, the expenses of production are greater than in the case of the orange. Until recently the increased tariff has to some extent offset this difference and at present the acreage of bearing lemons is being increased very rapidly.

Practically all varieties of any value in the Old World were introduced into California and tested out in the early days. Most of them, however, were not suited to our climatic conditions. Fifteen years ago the list had been reduced to six, namely the Eureka, Lisbon, Villa Franca, Genoa, Bonnie Brae and Messina. Five years ago the list had shrunk to three varieties, the Eureka, Lisbon and Villa Franca. Today the Eureka is practically the only variety widely planted, although there are many old orchards of the other varieties still in bearing. The Eureka is a seedling which originated in Los Angeles. During the years of its propagation it has split up into several strains, some of which are very much more desirable than others. The best strain of Eureka is precocious, vigorous, prolific, thornless and almost seedless. The chief objections to the Eureka are its habit of throwing out long, ungainly branches which fruit on their ends, and the thinness of the foliage in the springtime which allows a good many lemons to sunburn.

While the orange requires only a medium amount of pruning, the lemon tree demands almost constant attention. The young tree should be regularly pinched back and built up wholly of short, stocky branches, strong enough to bear a heavy load. All growth is cut off at some arbitrary level, at 8 to 10 feet from the ground. A great many vigorous young shoots will arise from the top and should be removed twice each year, once in the spring and again in late summer. In addition to this, many of the large growers keep a gang of expert pruners occupied the year round cutting out the weak and decadent branches and thinning the fruiting brush. One experienced pruner working continuously will care for 25 to 40 acres of Eureka lemons, and a somewhat less amount of Lisbons, which are very thorny and not easily handled. J. Eliot Coit.

LEMON VERBENA: *Lippia.*

LEMON VINE: *Pereskia.*

LEMÒNIA: *Ravenia;* see *Limonia.*

LENOPHÝLLUM (*trough leaf*). *Crassulàceæ.* A genus established by J. N. Rose in 1904 for *Sedum guttatum* and other species: perennial herbs branching at the base: lvs. a few opposite pairs clustered near the base, very thick and somewhat flattened and more or less concave on upper surface: fls. yellow (or drying reddish) in an erect infl. or solitary; sepals 5, equal, nearly distinct; petals erect, distinct, spreading or recurved at top; stamens 10: carpels narrow and erect. —Species about a half-dozen, Mex. and Texas. They are tufted plants a few inches high, to be treated like cotyledons or echeverias. *L. guttàtum,* Rose, and *L. Weinbergii,* Brit., are the names most likely to appear; both are Mexican. L. H. B.

LÉNS (ancient name of the lentil). *Leguminòsæ.* The lentil is one of the important food plants of the human race, although little grown in North America.

Closely allied to Vicia, from which it is distinguished chiefly by the 2-ovuled ovary and 1–2-seeded pod, Vicia usually having more than 2 seeds. Low erect or partially climbing herbs: lvs. pinnate, the terminal lft. sometimes ending in a bristle or tendril, the lfts. 2 to many pairs and entire: fls. small, bluish white, racemose or solitary, papilionaceous; calyx-lobes nearly equal and elongated; standard broadly obovate or nearly orbicular; wings oblique, obovate, partially adhering to the short keel: pod compressed, 2-valved, 1–2-seeded; seeds lenticular.—Species about a half-dozen, in the Medit. region and W. Asia, apparently only one of economic importance.

esculénta, Moench (*Érvum Léns,* Linn. *Vícia Léns,* Coss. & Germ.). Lentil. Annual, much-branched, 1–1½ ft. high: lvs. with numerous oval or oblong-oval lfts., ending in a tendril: fls. small, white or pale blue, axillary, in pairs: pods short and broad, very flat, and containing 2 flat seeds rounded in outline and convex on both sides. S. Eu.—The lens of the astronomer and physicist was named because it was shaped like one of these seeds. Some varieties have gray seeds, others red. Esau sold his birthright to Jacob for a mess of red pottage made of lentils. The seeds are used chiefly for soups and stews. They are a coarser and cheaper food than fresh peas and beans, and about as palatable as split peas. Lentils rank amongst the most nutritious of vegetables. They are also of the easiest cult., but the seeds are often destroyed by a weevil. There are many cult. varieties. The seed is usually sown in drills in March, 18–30 in. apart. The heaviest crops are produced on rather dry sandy soils. The plants need no special care between seedtime and harvest. The seeds keep better in the pods than after being threshed. The herbage makes good fodder. See Cyclo. Amer. Agric., Vol. II, p. 308. L. H. B.

LENTIL: *Lens.*

LEONÒTIS (Greek, *lion's ear,* which the flowers are supposed to resemble). *Labiàtæ.* Lion's Ear. Lion's Tail. This includes a tender shrub with scarlet-orange, gaping flowers, cultivated outdoors in southern Florida and southern California; and it is an excellent winter bloomer under glass.

Annual or perennial herbs, coarse and tall: lvs. opposite, petiolate, ovate: fls. white or yellow in very dense axillary whorls; calyx 8–10-ribbed, the tube arched and funnel-shaped; corolla-tube as long as calyx; upper lip long and concave, outside hairy; lower lip deflexed, the 3 lobes nearly equal; stamens 4, arched, didynamous; style 2-lobed.—Species about 20 in Trop. and S. Afr., one more widely dispersed.

Leonùrus, R. Br. Branched perennial with hairy sts., shrubby, 3–6 ft. high: lvs. 2 in. long, lanceolate or oblong-lanceolate, obtuse, coarsely serrate, narrowed at the base, pubescent: corolla more than thrice as long as the calyx, red-yellow or orange-red, 1½–1¾ in. long, pilose, the upper lip large and the lower small; stamens not exserted. S. Afr. B.M. 478 (as *Phlomis Leonurus*). R.H. 1857, p. 548. Gn. 53, p. 460. G.C. II. 19:186; III. 43:139. J.H. III. 53:255. G.W. 7, p. 100; 13, p. 14. G. 8:22; 13:313; 36:65. R.H. 1913, p. 92. Var. **globòsa nàna,** is a dwarf form, not exceeding 2½ ft. in all, and with a regular and rounded habit of growth. It is said that *L. Leonurus* has become a menace in S. Afr., with laws to provide for its destruction. In the North, Leonotis cuttings should be started in early spring, the young plants transplanted to the open in May and thereafter frequently pinched to make a symmetrical instead of a straggling bush, and if the plants do not flower before frost, they can be cut back, lifted and brought into a cool greenhouse to flower in Nov. or Dec. A southern enthusiast says that they are as easy to cult. as a geranium. There is a white fld. form.

L. dysophýlla, Benth., has orange-yellow fls., and differs from L. Leonurus also in the broader lvs. and longer calyx-teeth. S. Afr. B.M. 8404.—*L. nepetæfòlia,* R. Br. Annual, 1½–6 ft., with 4-angled st.: lvs. ovate, round-toothed; bracts spinescent: fls. yellow or orange-red, in distant-globose bur-like whorls; corolla 1 in. long. Many tropics; reported as a showy plant in Porto Rico.

Wilhelm Miller.
L. H. B.†

LEONTÍCE (Greek, *lion's foot;* referring to the shape of the leaf). Including *Bongárdia. Berberidàceæ.* Lion's Leaf. Hardy herbaceous perennials, chiefly Asian, of low growth and distinct appearance.

Tuberous: lvs. pinnate or pinnatisect, on the st. small or none: fls. yellow, racemose or in a somewhat dichotomous cyme; sepals petal-like, 3–9; petals 6, often reduced to small nectaries; stamens 6, free: carpel 1, becoming a bladdery nearly or quite indehiscent caps.—Species perhaps a dozen, S. Eu. to Cent. Asia. Likely to be advertised with Dutch bulbs. These plants have a turnip-shaped corm or rhizome about 2 in. thick, and bear yellow fls. in early spring. Bongardia, now included in Leontice, has only one species.

A. *Petals reduced to scales or nectaries.*

B. *Lvs. twice ternately cut.*

Leontopétalum, Linn. Height 1–1½ ft.: lfts. ovate or obovate, rarely subcordate: panicle large, dense, leafy. Italy and the Orient.—Root used in the Holy-land. against epilepsy.

BB. *Lvs. digitately cut.*

C. *Raceme dense, conical.*

Álberti, Regel. Sts. several, stout, each giving off 2 subradical lvs. which are undeveloped at flowering-time: lvs. finally on stalks 4–5 in. long, digitately 5-parted; lfts. pale green, glaucous, elliptic; nerves prominent and parallel beneath: scape 6–8 in. high, robust; raceme as many as 18-fld.; fls. nearly 1 in. across, ochre-yellow, streaked reddish brown on back; petals shorter than the stamens. Turkestan. B.M. 6900. Gt. 1881:1057.

CC. *Raceme loose, oblong.*

altàica, Pall. Lvs. not from the root, digitately cut, only 1 lf. on each fl.-st., the lf. having 3 primary divisions, each of which is petioled and has 5 lfts., 2 of which are smaller than the rest; lfts. elliptical: infl. a raceme, bearing large, more or less roundish leafy bracts; fls. mostly erect, having 6 showy, oblong, not overlapping, entire parts supposed to be sepals, the petals small, yellow, erect, shorter than the anthers. S. Russia, Altai, Siberia. B.M. 3245.

AA. *Petals large and prominent.*

Chrysógonum, Linn. (*Chrysógonum Dioscorìdis,* Rauw. *Bongárdia Raùwolfii,* C. A. Mey). Of the subgenus Bongardia. Lvs. all from the root, pinnate; lfts. 3–8 pairs, or some of the lfts. in whorls of 3–4, wedge-shaped, 3-fid. with a conspicuous triangular crimson mark at the base of each: infl. a panicle, bearing minute, linear bracts; fls. drooping, having 6 showy, wedge-shaped, crenate parts, 3 of which should possibly be considered petals, and the other 3 inner sepals, since there are 3 small, greenish lobes outside which are like an ordinary calyx, and should, perhaps, be called the outer calyx. B.M. 6244. F.C. 3:98. B. 1:50.

Wilhelm Miller.

LEÓNTODON (Greek, *lion's tooth*). *Compósitæ.* A rather weedy group of hardy perennials little grown in Amer. and not unlike the hawkweeds. They are scapose herbs with clustered, basal lvs. much pinnatifid, scapose, with many-fld. heads of rather showy yellow fls.: involucre ovoid or oblong, its bracts in 1 or 2 series; pappus of plumose bristles, differing in this from Hieracium, its nearest horticultural relative.

L. autumnàle, Linn., Fall Dandelion, is sometimes cult. in Amer. It becomes weedy, but its late-flowering yellow heads are attractive to some. Eu., but naturalized in E. N. Amer. N. Taylor.

LEONTOPÒDIUM (Greek, *lion's foot*). *Compósitæ.* Perennial herbs, all tufted and woolly, of which the edelweiss is perhaps the one flower most sought by tourists in the Alps. It is an emblem of purity.

Stems ascending or erect, unbranched except at the very top: st.-lvs. alternate, entire: heads small, crowded into dense cymes surrounded by a sort of leafy involucre.—About 6 widely scattered species. Edelweiss is still catalogued as a Gnaphalium, but in that genus the style is 2-cut, while in Leontopodium it is uncut. Leontopodium is more nearly allied to our common weed, the "pearly everlasting" (*Anaphalis margaritacea*), which lacks the dense cluster of star-like floral lvs., but in the opinion of some has as much beauty as the edelweiss.

The edelweiss is a low plant, 4 to 12 inches high, densely covered with a whitish wool, the attractive portion being the flat star-like cluster of woolly floral leaves surrounding the true flowers, which are small, inconspicuous and yellow. The general impression seems to be that edelweiss cannot be cultivated in America. In 1900, however, it was extensively advertised as a pot-plant, and it has long been cultivated in rock-gardens. J. B. Keller says, "It can be grown to perfection in an elevated position of the rockery, in rather light soil and with full exposure to sun. It also succeeds in an ordinary hardy border where the plants can be kept moderately dry in winter."

Seeds of edelweiss should be sown about February 1, which gives plants large enough to plant out in permanent quarters about May 1. If planted in good well-drained ground, the plants are sure to make a good growth so that by the middle of September there will be an occasional flower. However, it is not until the following year that one gets a full crop of flowers, so many in fact that it seems to exhaust the plants, which should now receive a good deal of care. Old plants divided early in the fall and wintered in coldframes give very good results, or late-sown seedlings carried over winter in the same way do well. (Albert E. Robinson.)

To establish a colony of edelweiss an English writer (Gn. 52, p. 146) advises that a few stray seedlings be firmly planted in a narrow chink of rock so placed that a deep fissure of gritty or sandy loam may be assured for the roots to ramble in. Plants in pots may be grown and flowered when the collar is tightly wedged between some pieces of stone or old mortar. The plant is best propagated by seeds, as division is not always successful.

2132. Edelweiss.—Leontopodium alpinum. (×¼)

alpìnum, Cass. (*Gnaphàlium Leontopòdium,* Linn. *L. himalayànum,* DC.). Fig. 2132. Creeping by stolons: lvs. lanceolate, white-tomentose beneath, floral ones oblong: fl.-heads 7–9 in a cluster; involucral scales woolly at base, blackish at apex. B.M. 1958. Gn. 29, p. 529; 52, p. 146; 60, p. 344; 62, p. 145. G.L. 18:47; 24:181.

sibíricum, Cass. St. simple, bearing numerous oblong-linear, often webby lvs.: fls. borne in a densely corymbose cluster, white, and nearly twice the size of the preceding. Russia.—Can be grown readily at much lower elevations than *L. alpinum.*

L. japónicum, Miq. (Gnaphalium Sieboldianum, Franch. & Sav.). Fls.-heads looser: lvs. shining dark green above, underneath silvery. N. Taylor.†

LEONÙRUS (Greek compound, meaning *lion's tail*). *Labiàtæ.* About 10 species of herbs, some of them weedy and widespread, but scarcely horticultural subjects. *L. Cardìaca,* Linn. (*Cardìaca vulgàris,* Moench. *L. villòsus,* Desf.), is the common motherwort: weed or escape about buildings and in waste places, from Eu.: perennial, tall, with long-petioled lvs., the lower 3-cleft: fls. purple (sometimes white) bearded, in axillary whorls; calyx with prickly teeth. Said to be a good bee-plant.

LÉPACHYS (Greek, *a thick scale;* probably referring to the thickened upper part of the bracts of the receptacle). Including *Ratibida. Compósitæ.* Annual or perennial herbs, the most popular of which is a fine prairie wild-flower, *L. columnaris,* for which, unfortunately, there is no common name.

Lepachys contains 4 species of herbs, all American, 3 perennial: lvs. alternate, pinnately divided or parted: disks at first grayish, their corollas yellowish, becoming tawny; chaffy bracts commonly marked with an intermarginal purple line or spot, containing volatile oil or resin; achenes flattened, sharp-margined or winged. For generic distinctions, see *Rudbeckia.*

Lepachys columnaris grows 2 to 3 feet high, has elegantly cut foliage, and bears flowers something like a brown-eyed Susan, but the disk is finally cylindrical and more than an inch high, with 6 or 7 oval, reflexed rays hanging from the base. In a fine specimen these rays are 1½ inches long and nearly 1 inch broad. There are 5 inches or more of naked wiry stem between foliage and flower. Typically, the rays are yellow, but perhaps the most attractive form is var. *pulcherrima,* which has a large brown or brown-purple area toward the base of each ray. Like the greater number of our native western flowers that are cultivated in the eastern states, the plants have reached our gardens from European cultivators. Meehan says it is perfectly hardy in our northern borders, but the English do not regard it as entirely safe without some winter protection. Moreover, it is one of the easiest herbaceous perennials to raise from seed, flowering the first year, and it is chiefly treated in the Old World as an annual bedding plant, the seeds being known to the trade as *Obeliscaria pulcherrima.* For bedding, the seeds are sown in early spring in a hotbed, the seedlings pricked off into boxes, hardened off, and finally transplanted to the open, only slight care being necessary to obtain compact bushes about 2 feet high. Under such circumstances the plants flower from June to September, and the season may be prolonged by a sowing in the open. This has proved useful in our northern borders, where seed should be thinly sown in the open, where the plants are to stand, with a fair chance of autumnal bloom the same year. The flowers last well in water and should be cut with long stems to get the benefit of the delicately-cut foliage. *L. pinnata* is perfectly hardy at New York and is a serviceable perennial.

A. *Rays oval, scarcely as long as the disk at its longest: lf.-segms. linear.*

columnàris, Torr. & Gray (*Ratíbida columnàris,* D. Don). Fig. 2133. A rough-pubescent perennial, branching from the base, 1–2½ ft. high in the wild, often higher in cult.: st.-lvs. with 5–9 divisions, which are oblong to linear in outline and sometimes 2–3-cleft: fls. solitary, terminating the branches; rays yellow; style-tips short, obtuse. Prairies, Saskatchewan to Texas and Rocky Mts. B.M. 1601. Mn. 1:65.

2133. Lepachys columnaris. (×¼)

Var. **pulchérrima,** Torr. & Gray (*Obeliscària pulchérrima,* DC.), differs only in having the rays partly or wholly brown-purple. The plants in the trade are mostly margined with yellow or have about half of each color. Gn. 51:98. R.H. 1854:421. Var. **tòtus purpùreus,** Hort. D. M. Andrews, is "a variety with dark orange-brown rays, almost black."

AA. *Rays oblong-lanceolate, very much longer than the disk: lf.-segms. lanceolate.*

pinnàta, Torr. & Gray (*Ratíbida pinnàta,* Barnh.). Slender, 3–5 ft. high: lvs. with 3–7 lfts., which are lanceolate, sparsely serrate, sometimes lobed, the uppermost run together, very rough-hairy: rays yellow, often 2 in. or more long. W. N. Y. to Ia., south to La. B.M. 2310. Gn. 47:418; 51, p. 205.—It is at home in a sunny border.

J. H. Cowen.
N. Taylor.†

LEPÁNTHES (*scale flower*). *Orchidàceæ.* Some forty species of the mountains and upper parts of Mex., Cent. Amer., W. Indies and S. Amer., epiphytic, monophyllous, allied to Pleurothallis but differing in bearing club-shaped pollinia and a usually 2-parted lip that is adnate to the column. None is offered, and the species are of little importance horticulturally.

LEPICÝSTIS: *Polypodium.*

LEPIDÁGATHIS (Greek, *scale* and *ball,* in allusion to the curved infl.). *Acanthàceæ.* Tropical herbs and shrubs; one is in horticultural literature as a warmhouse evergreen shrub. It is *L. cristàta,* Willd., in Trop. India, with purplish fls., linear or oblong nearly glabrous lvs. and spinose-acuminate bracts and bracteoles: fls. in globose clusters or heads near the base of the plant; corolla ⅓in long, in bud densely hairy, white with purple or brown spots: sts. 6–24 in., procumbent. Lepidagathis has about 50 species, of which two are in the American tropics and the others in the Old World. It is little known to cultivators.

LEPÍDIUM (from Greek for *little scale,* alluding to the small flat pods). *Cruciferæ.* Cress. Pepper-Grass. Small mostly unattractive herbs (or rarely subshrubs), one of which is a salad plant. See *Cress.*

Annual, biennial or perennial, erect or spreading, with many small white fls.: lvs. very various, simple to more or less bipinnate: fls. mostly racemose, often with leafy bracts intervening; petals small or wanting; stamens 2–6: pod circular, flattened against or contrary to the partition; seed 1 in each cell; cotyledons in most cases incumbent.—Perhaps 100 species in many parts of the world. There are about 20 native species, mostly western, and several intro. weedy species. The foliage and pods have an aromatic-peppery flavor. The herbage of some species is used as salad, and the pods are sometimes fed to tame birds (whence the name "canary grass"). There are no species of much ornamental value.

satìvum, Linn. Garden Cress. Annual, 1–2 ft., glaucous when in fl. and fr., glabrous: fls. small and inconspicuous, in an elongating raceme: pods nearly circular, bifid at the apex, winged: lvs. exceedingly various, but usually the radical ones pinnately divided and subdivided, the central cauline ones 2–3-cleft, nearly to the base and the segms. entire or toothed, the uppermost simple and entire. W. Asia, but widely disseminated as a cult. plant, and sparingly run wild in the northern part of the U. S. and Canada.—Under cult. the foliage varies immensely. The curled sorts have lvs. as finely cut as curled parsley. On Australian cress, which is a golden-lvd. form, there are sometimes on the same plant broad-spatulate, ragged-edged lvs., cut lvs., and simple linear lvs.

Other lepidiums are sometimes eaten, but are not in the trade and are of little importance. One of these is the common *L. virgínicum,* Linn., wild in the U. S., and known as pepper-grass.

L. H. B.

LEPTACTÌNA (Greek, *graceful rays,* referring to the star-like aspect of the flower). Also written *Leptactinia. Rubiàceæ.* Showy shrubs, glabrous or puberulent, leafy: lvs. opposite, glossy; stipules broad-ovate and mostly rather large: fls. in dense terminal cymes, like ixoras, white.—The genus contains about 25 species, all Trop. African shrubs, important generic characters being the large calyx-lobes, very long corolla-tube, 5 included stamens, style-branches free or connate, large lax stipules, and clustered infl.

L. Mánnii, Hook. f. Branching shrub, 6 ft. high: lvs. 5½ in. long, 2½ in. wide and larger in proportion, oval, wavy-margined, obtuse, with gobose green bodies between the insertions of the lvs., which are stipules: calyx-tube 3 lines long, lobes 1 in. or more long, leafy; corolla silky within, lobes lanceolate; stamens 5, included; style hairy above, 2-branched. B.M. 7367.—A very interesting white-fld. shrub for growing under glass, apparently not offered in this country.

L. H. B.

LEPTÁNDRA: *Veronica.*

LEPTARRHÈNA (name refers to the slender or thin anthers). *Saxifragàceæ.* One perennial caulescent herb, *L. pyrolifòlia,* R. Br. (*L. amplexifòlia,* R. Br *Saxífraga pyrolifòlia,* Don), from Kamtschatka and Alaska to Wash., sometimes mentioned in horticultural literature: caudices short and leafy, the lvs. alternate, leathery and evergreen, toothed, narrow to base, the radical ones 1–4 in. long and obovate to oblong or spatulate, those on the fl.-stalks 1 or 2 and clasping: fls. small, white, in bracted panicles, on scape-like sts 8–16 in. high; sepals 5, erect; petals 5, narrow, persistent; stamens 10; ovary of 2 nearly distinct carpels, becoming follicles. Probably a good plant for wild-gardening where proper conditions can be found; recorded as growing "in high mountain marshes."

L. H. B.

LEPTINÉLLA: *Cotula.*

LEPTOCÁRPHA (name refers to the slender scales or chaff). *Compósitæ.* A subshrub from Chile and Peru that has been grown abroad for the yellow fl.-heads. *L. rivulàris,* DC., the only species, has alternate or sometimes opposite ovate, toothed, and scabrid lvs. about 2 in. long, and heads about 1 in. diam. A half-hardy or greenhouse plant allied to Helianthus.

LEPTOCHÌLUS (from the Greek referring to the linear form of the fruiting frond). *Polypodiàceæ.* A group of moderate-sized tropical ferns, allied to Dryopteris, but formerly classified under Acrostichum. The lvs. are pinnately divided; the sporangia are borne very close together so that at maturity they appear entirely to cover the backs of the fertile lvs.

aliènus, Swartz (*Acróstichum aliènum*, Swartz). Sterile lvs. 1–2 ft. long, triangular, with the upper pinnæ decurrent, and the lower at least sinuate or even incised; fertile lvs. smaller, with narrow pinnæ, the upper decurrent. Cuba and Mex. to Brazil.

nicotianæfòlius, C. Chr. (*Acróstichum nicotianæfòlium*, Swartz). Sterile lvs. with 3–7 pinnæ which are 6–12 in. long and 2–3 in. wide, with nearly entire edges; fertile lvs. smaller, with 3–7 pinnæ 3–4 in. long, 1 in. wide. W. Indies to Brazil. R. C. Benedict.†

LEPTOCHLÒA (*slender* and *grass*, from the Greek, referring to the slender spikes). *Gramíneæ*. Annual or perennial grasses with rather showy inflorescence, one species occasionally grown for ornament.

Plants with flat blades and slender unilateral spikes arranged along a main axis: spikelets 2- to several-fld.—Species about 12, in the warmer regions of both hemispheres. Differs from Chloris and other genera of the tribe Chlorideæ, in having racemosely arranged spikes with several-fld. spikelets.

virgàta, Beauv. Erect, glabrous, usually glaucous perennial, 2–4 ft.: spikes numerous, 3–6 in., on an axis 3–6 in. long; spikelets 3–6-fld.; florets awnless or with an awn shorter than the body. Trop. Amer.—Has been advertised under the name of *Chloris gracilis*. A pleasing grass with feathery infl. suitable for borders in the South. A. S. Hitchcock.

LEPTOCÒDON (*slender bell*, from the shape of the flowers). *Campanulàceæ*. Twiner, suitable for the greenhouse. From Campanumæa it differs in bearing a dehiscent caps. rather than a fleshy berry, and from Codonopsis in having a tubular upwardly inflated rather than mostly campanulate corolla. The single species is *L. grácilis*, Hook. f. & Thom. (*Codonópsis grácilis*, Hook. f. *Campanumæ̀a grácilis*, Hort.), of Sikkim (India): glabrous slender perennial with alternate and opposite long-stalked ovate-crenate lvs.: corolla 1–1½ in. long, blue, tubular-curved, shortly 5-lobed, the calyx very deeply 5-lobed; stamens 5, free, with as many glands intervening; fls. terminal and opposite the lvs., single on slender peduncles. L. H. B.

LEPTODÁCTYLON: *Gilia*.

LEPTODÉRMIS (Greek, *leptos*, thin and *derma*, skin, membrane, referring to the thin membranous bractlets connate into a tube.) *Rubiàceæ*. Low shrubs with small foliage, and small tubular white or purplish flowers in usually few-flowered clusters appearing during summer and fall when few shrubs are in bloom.

Slender-branched, with opposite small entire stipulate lvs.: fls. in axillary head-like clusters; calyx 5-toothed, persistent; corolla tubular-funnelform, with 5-lobed limb; stamens 4, included; ovary inferior, 5-celled; style slender, 5-parted at the apex: fr. a caps., the outer wall splitting to the base into 5 valves, the inner net-like, closed, enveloping the seed.—About 10 species in China and Himalayas. Interesting for botanical collections as one of the few woody representatives of Rubiaceæ which are hardy north. A few species have been recently intro. from China, of which the following has proved fairly hardy at the Arnold Arboretum, but appears to be short-lived. Prop. by greenwood-cuttings in summer and by seeds.

oblónga, Bunge. Shrub, to 3 ft.: lvs. oblong or elliptic-ovate, acute, narrowed at the base into the short petiole usually scabrid, ½–¾in. long: fls. in sessile, dense and few-fld. clusters; corolla slender, tubular, with oblong-lanceolate spreading lobes, puberulous outside, violet-purple, ¾in. long; style exceeding the hairy mouth. N. China. July–Oct. Alfred Rehder.

LEPTOLÆLIA. Hybrid of *Leptotes bicolor* (seed parent) and *Lælia cinnabarina*, known as *Leptolælia Veitchii*.

LEPTÓPTERIS (Greek, *cut fern*, alluding to the filmy texture of the lvs.). *Osmundàceæ*. About 6 greenhouse ferns with sporangia like those of Osmunda but with filmy lvs. like those of Hymenophyllum. These sporangia grow on the backs of the lvs. as in ordinary ferns. A group of beautiful ferns which require special cult. All are from the Australasian region. Allied to Todea.

supérba, Presl. With an erect woody st. 12–18 in. high; lvs. 2–4 ft. long, 6–10 in. wide, tripinnatifid, pinnæ close together, narrow, reduced below. New Zeal. R. C. Benedict.

LEPTÓSIPHON (name alludes to the slender flower). *Polemoniàceæ*. A genus founded by Bentham, but now made a section or subgenus in Gilia. *L. densiflòrus*, Benth. (*G. densiflòra*, Benth.), is a common garden annual, by some now separated as *Linánthus densiflòrus*, Benth., native in California. *Leptósiphon aùreus* and *L. hýbridus* are accounted for under *Gilia micrantha* (p. 1337).

LEPTOSPÉRMUM (Greek, *slender seed*). *Myrtàceæ*. Ornamental woody plants grown chiefly for their copiously produced flowers and also for the neat myrtle-like foliage.

Evergreen shrubs or small trees: lvs. alternate, small, rigid, entire, nerveless or 1–3-nerved: fls. short-stalked or sessile, solitary or 2–3, axillary or at the end of short branchlets; sepals short and broad; petals roundish, clawed, spreading; stamens many; ovary inferior, inclosed in the calyx-tube, 3–10-celled; style short: fr. a loculicidal caps., usually protruding above the calyx-tube; seeds numerous, linear, or few and compressed and winged.—There are about 25 species mostly in Australia, few in New Zealand and in the Malay Archipelago.

The leptospermums in cultivation are upright shrubs with slender branches densely clothed with small rigid foliage and covered in spring with numerous white, rarely pink or carmine flowers ½ to ¾ inch across; the capsules are small and insignificant. They are cultivated somewhat outdoors in California, or in the North in the greenhouse and treated like heath and other Cape and Australian hardwood plants. Planted outdoors they stand drought well and *L. lævigatum* has been employed by the hundred thousands in the reclamation of the moving sands on the San Francisco promontory where the Golden Gate Park is now established. For greenhouse culture, *L. scoparium* var. *bullatum* is an exceptionally good plant for those who can grow heaths. It is far better than *L. lævigatum*.

Cuttings taken from well-ripened wood in the fall or from the young growth in summer root freely under the same treatment given erica. For a potting soil, use two parts leaf-mold and one of sand. Plunge the pots outside during the summer in the full sunlight. The plants make a straggling growth, unless trimmed into shape. By fall they will be covered with buds, but it is impossible to force them into bloom for Christmas. Keep the plants in a cool house with ericas or azaleas until the latter part of February or March, and then give them a little more heat, say 55° to 60°. The plants will soon be a mass of white flowers. *L. scoparium* var. *bullatum* does not grow rapidly, but, like epacris, as it grows older it makes fine specimens. It has tough foliage, stands much hard usage, and when in bloom attracts plant-buyers. It deserves greater popularity.

Propagation is by seeds sown in spring and treated like those of erica or rhododendron, but usually by cuttings of young wood in May under glass, or of nearly mature wood in autumn and kept in winter in temperate house.

A. *Ovary usually 10-celled.*

lævigàtum, F. Muell. Tall shrub, attaining 20–30 ft., glabrous and somewhat glaucous: lvs. varying from obovate-oblong to oblong-cuneate or narrow-oblong, obtuse, ½–1 in. long, 3-nerved: fls. white; calyx glabrous: caps. slightly protruding above calyx-tube. Austral. B.M. 1304 (as *Fabricia lævigata*). G.C. II. 25:816; III. 9:45.

AA. *Ovary usually 5-celled.*

B. *Calyx-tube glabrous.*

C. *Lvs. flat or with recurved margins, obtuse or scarcely pointed (except in the large variety).*

flavéscens, Smith. Tall shrub: lvs. usually narrow-oblong to linear-lanceolate or broadly oblong or even obovate, ½–¾in. long: fls. about ½in. across, white. Austral. B.M. 2695. Var. **obovàtum,** F. Muell. Lvs. broadly obovate to obovate-oblong, under ½in. long. Cult. in Eu. under glass. Var. **grandiflòrum,** Benth. & Muell. Lvs. rather larger: fls. larger than in any other variety. L.B.C. 6:514.

CC. *Lvs. flat or concave, sharp-pointed, narrow or small.*

scopàrium, Forst. Attaining 10–12 ft.: lvs. ovate to linear-lanceolate or linear, mostly under ½in. long. Otherwise, almost exactly as in *L. flavescens.* Var. **junipérinum,** Nichols. (*L. junipérinum,* Smith). A narrow-lvd. form with pubescent pendulous branchlets. Var. **bullàtum,** Rehd. (*L. bullàtum,* Hort.). Lvs. larger, narrow: fls. larger, about ¾in. broad. G.C. III. 51:100. G. 30:415. R.H. 1903, p. 375. R.B. 30, p. 44. J.H. III. 30:435. Var. **Níchollii,** Turrill. Fls. carmine: lvs. purple, but green in plants grown under glass. Gn. 77:612. B.M. 8419. R.H. 1912:520. Var. **grandiflòrum,** Hook. Fls. large, pink or nearly white. B.M. 3419. Gn. 51:390. Var. **Chápmannii,** Dorrien Smith. Lvs. brownish: fls. bright rose. New Zeal. Var. **Bóscawenii,** Bois. Fls. 1 in. across, cherry-red in bud, white with reddish center when expanded. New Zeal. R.H. 1912:520. G.C. III. 51, suppl. One of the most desirable forms. It is said to be of relatively easy cult., with compact habit, the branches spreading in all directions. Excellent plants for the amateur, but very slow-growing. *L. scoparium* is the manuka or tea-tree of New Zeal.

BB. *Calyx-tube more or less densely clothed with silky or woolly hairs.*

pubéscens, Lam. (*L. lanigerum,* Smith). Tall shrub or small tree: branchlets villous: lvs. varying from obovate-oblong to elliptic or narrow-oblong, normally ½in. long, silky-villous while young, rarely glabrous: fls. ½–¾ in. across, white. Austral. L.B.C. 8:701; 12:1192. B.M. 1810. I.H. 32:570. G.C. II. 12:427. Gn. 19:42, and 27, p. 145. G. 29:642.—Extremely variable. Long cult. abroad, but not advertised in Amer.

L. flexuòsum, Spreng. (Agonis flexuosa, Schauer). Tall shrub or tree, to 40 ft.: branchlets at first pubescent, finally glabrous: lvs. lanceolate or linear-lanceolate, 3-nerved, ¼–½ in. long: fls. white, over ⅓in. across, in axillary heads; calyx pubescent, stamens 20. Austral.—This species is now generally referred to Agonis which differs from Leptospermum chiefly in the capitate infl. and in the cells of the ovary having only 2–6 ovules ascending from a basal placenta.

Alfred Rehder.†

LEPTÓSYNE (Greek, *slenderness*). *Compósitæ.* Yellow-flowered composites, with much-divided foliage like cosmos.

Smooth and glabrous herbs and subshrubs: lvs. alternate or opposite, usually rather fleshy, and ternately or pinnately divided or dissected. They are the representatives of Coreopsis on the western side of the continent, but have mostly pistillate rays and always a ring on the tube of the disk-fls.—Seven species, all from Calif. except *L. arizonica.* The genus is united with Coreopsis by some authors, including Hoffmann in Engler & Prantl.

In the North these plants are mostly treated as half-hardy annuals. None of them has anything like the popularity of either cosmos or *Coreopsis tinctoria.* The commonest species is *L. maritima,* but *L. Stillmanii* promises to outrank it, although not well known in the trade. *L. Stillmanii* is said to bear flowers 1½ inches across, for 5 or 6 weeks. Its seed germinates quickly and can be sown outdoors. Sandy soil and a sunny position are advised. It is said to bloom in four to five weeks after sowing. *L. maritima* should be started indoors, transplanted in May, and can be brought into flower by July. Two distinct plants are passing in the trade as *L. maritima,* one of which is *L. calliopsidea,* and is considered an inferior plant by some. The seeds of the two plants are easily distinguished.

A. *Rays obovate.*

B. *Seeds having long, soft, villous hairs.*

calliopsídea, Gray (*Agarísta calliopsídea,* DC. *Coreópsis calliopsídea,* Boland.). This is the plant figured in R.H. 1873:330, erroneously as *L. maritima.* Annual, 1–2 ft. high, rather stout and leafy: fls. 3 in. across, long-stalked; rays fewer, shorter and broader than in *L. maritima,* 1¼ in. long, ¾–1 in. wide.

BB. *Seeds having short, rigid bristles.*

Doùglasii, DC. (*L. califórnica,* Nutt. *Coreópsis Doùglasii,* Hall). Annual, 9–12 in. high: lvs. 1–3 times parted: fls. on solitary, long-stalked heads; ring of the disk-fls. distinctly bearded. June, July.

BBB. *Seeds not hairy.*

Stíllmanii, Gray. Stouter than *L. Douglasii* and more leafy below, surmounted by a single long-stalked head: ring of disk-fls. beardless. Gn. 52, p. 461. G.C. III. 22:333. R.B. 23, p. 275. Gt. 46, p. 612. S.H. 2:44. G.L. 23:293.—Intro. 1898, by Benary. Annual with linear (not filiform) lf.-lobes.

AA. *Rays oblong: perennials.*

B. *Sts. low, from a thick base.*

marítima, Gray (*Coreópsis marítima,* Hook. f.). Perennial: lvs. 2-pinnate: fls. 3½ in. across, borne at the ends of branches on peduncles 9–12 in. long; rays 16–20, 1½ in. long; disk 1 in. across: seeds not hairy. B.M. 6241. Gn. 49:272. Not R.H. 1873:330, which is really *L. calliopsidea.*—Makes a good bog-plant.

BB. *Sts. 2–8 ft. high, 1–5 in. thick, somewhat woody, often decumbent.*

gigantèa, Kellogg (*Coreópsis gigantèa,* Hall). Differs in being leafy at the top only, the others being leafy at the base: lvs. 2–3-pinnate: fls. smaller than in *L. maritima,* borne on short corymbose peduncles; disk ½in. across: seeds not hairy. Cult. in S. Calif. Gt. 44, p. 592. G.C. III. 28:319.—The fls. are said to be sweet-scented.

Wilhelm Miller.
N. Taylor.†

LEPTOTÆNIA (*narrow vittæ* or oil-tubes). *Umbelliferæ.* Several N. American tall perennial herbs, allied to Ferula and Angelica: glabrous: roots thick and fusiform: lvs. pinnately compound: fls. yellow or purple, in compound umbels, the involucre and involucels none or of few bracts: fr. oblong or nearly orbicular, much compressed. Two species were once listed, but probably none is in cult. Manuals of the plants of the Rocky Mt. region and west contain descriptions of the species.

LEPTÒTES (from the Greek, referring to the slender parts). *Orchidàceæ.* Small terrestrial or epiphytic herbs of slender habit bearing racemes with few pretty flowers produced in spring.

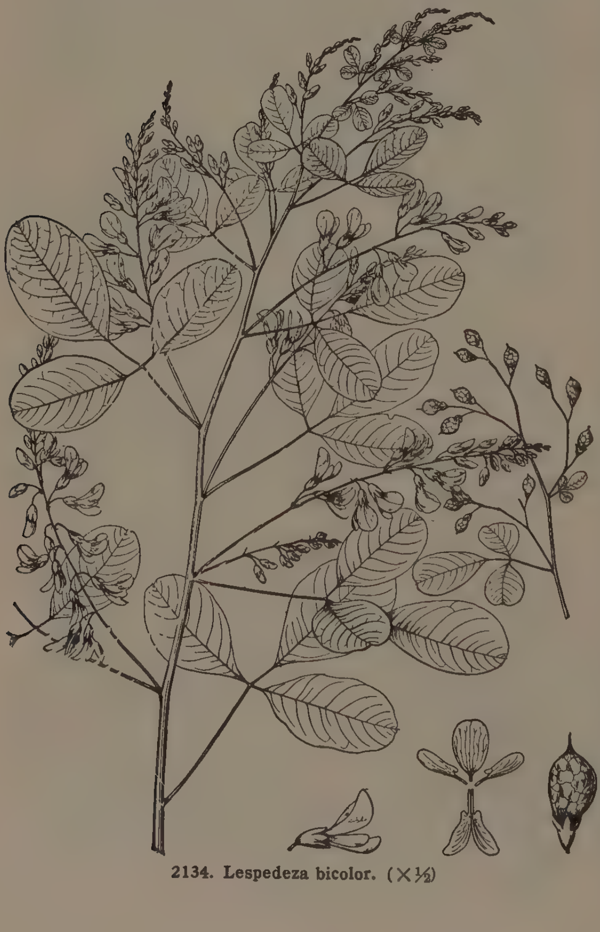
Stems erect, not pseudobulbous, growing from a creeping rhizome and bearing 1–3 fleshy linear lvs. and a slender but rigid, terminal raceme: sepals and petals nearly equal, spreading; labellum joined to the base of the column; lateral lobes large, spreading or small, auricle-like, middle lobe large, entire, contracted at base, column with 2 wide wings; pollinia 4 perfect and 2 imperfect.—Six species in Brazil and W. Indies. Cult. as for lælia.

bícolor, Lindl. (*Tetramìcra bícolor,* Rolfe). Lvs. solitary on the short st., semi-cylindric, with a furrow in front, 3–4 in. long: raceme few-fld., shorter than the lvs.; sepals and petals white, linear-incurved, over 1 in. long; lateral lobes of the lip small, folding over the column; terminal lobe oblong-lanceolate, bright rose, with white tip and margins. A pretty plant. B.R. 1625. A.F. 6:633. Gn. 59, p. 77. Var. **glaucophýlla,** Hook. Lvs. glaucous. B.M. 3734.

L. unícolor, Rodr. Habit pendulous: fls. pale lilac: lvs. fleshy. Brazil.

Heinrich Hasselbring.

LESCHENAÙLTIA (named for L. T. Lechenault, botanical traveler in the far E.). Written also *Lechenaultia. Goodeniàceæ.* About 20 species as understood by the latest monographer (Krause, in Engler's Pflanzenreich, hft. 54, 1912) of herbs and heath-like shrubs of Austral., sometimes grown under glass: glabrous or rarely hirsute: lvs. heath-like, scattered or crowded, narrow and entire: fls. yellow, red, violet or greenish, solitary or corymbed, showy, with a slender tube and large limb; calyx-tube adnate to ovary, the lobes 5 and linear or lanceolate; corolla oblique, the tube usually slit to the base, on the back, the lobes connivent or spreading; anthers mostly cohering around the style; indusium (or dilated top of style) 2-lipped with a partial ring of hairs outside: caps. linear, 4-valved, dehiscent. —The leschenaultias require special care in watering, and an open soil with plenty of fiber and sand. They are very handsome hardwooded plants for greenhouse growing, but seldom seen in this country.



2134. Lespedeza bicolor. (X½)

L. bíloba, Lindl. Shrub, 1–3 ft.: lvs. not greatly crowded, about ¼ or ⅓in. long: fls. blue and handsome, the corolla about ¾in. long, either few on the shoot or corymbed; lobes of corolla longer than tube, spreading, with dark blue veined wings and a point or mucro between. W. Austral.—*L. formòsa,* R. Br. (L. multiflora, Lodd. L. Baxteri, Don). Spreading and much branched, 1–2 ft.: lvs. rather loosely scattered, ⅓in. or less long: fls. solitary, red; corolla-tube split to base, 5 lines or less long; corolla somewhat bilabiate, the upper lobes broad and rounded, erect and connivent and shorter than the large and spreading lower ones. W. Austral. B.M. 2600. B.R. 916. L.B.C. 16:1579.—*L. grandiflòra,* Lindl., is a large-fld. form of L. biloba.—*L. larícina,* Lindl. (L. splendens, Hook.). Much branched, erect, 1 ft.: lvs. fine, rather crowded: fls. white to lilac to red, sessile in upper axils; tube of corolla ½in. long, slit to base; lobes of corolla all similar, usually shorter than the tube. W. Austral. B.M. 4256. F.S. 2:176. H.F. II. 6:14.—*L. spléndens,* Hook.=L. laricina.

L. H. B.

LESPEDÈZA (D. Lespedez was a Spanish governor of Florida, who aided the botanist Michaux). *Leguminòsæ.* Bush Clover. Small shrubs or herbs with pea-shaped flowers in racemes or heads, some of them very ornamental but mostly not showy; one extensively used for forage.

Leaves pinnately 3-foliolate or rarely 1-foliolate, the lfts. entire and wanting stipels: calyx-lobes nearly equal, sometimes subulate; anthers usually 9 and 1: pod short and 1-seeded (and in this differing from Desmodium, which has jointed pods).—Species 40 or more, in N. Amer., Asia and Austral., most of them not known horticulturally. In some of the lespedezas there are 2 kinds of fls.,—petal-bearing and mostly sterile, apetalous and mostly fertile. There are a number of native lespedezas, usually of dry lands, some of which are offered by dealers in native plants, but they are not very showy and are most in place in natural borders and in amateur collections. These species thrive in light, dry soils. Because of the grayish or brownish color of the foliage, they are sometimes useful in landscape gardening work, and they are hardy, and of easiest cult.; perennial. Two or 3 of the oriental species are now becoming popular. *L. striata* is the Japan clover of the S., and is a valuable forage and green-manure plant. *L. bicolor* is a low shrub, with small violet-purple fls., hardy in New England, but little known in cult. The most important ornamental members of the genus thus far well known are *L. Sieboldii* and *L. japonica,* which are hardy herbs or subshrubs sending up many strong wiry shoots each year, and blooming profusely in Sept. and Oct. Their late bloom is very desirable. All lespedezas are of the easiest cult. wherever hardy. Usually increased by division of the clumps. *L. Sieboldii* is readily prop. by greenwood cuttings under glass.

INDEX.

albiflora, 10.
bicolor, 8, 19.
capitata, 2.
formosa, 9.
frutescens, 6.
hirta, 1.
intermedia, 6.
japonica, 10.
Nuttallii, 4.
racemosa, 9.
Sieboldii, 9, 10.
striata, 7.
Stuvei, 5, 6.
violacea, 3.

A. *Occidental or native lespedezas: of upright or erect habit, not showy: stipules and fl.-bracts minute, subulate.*

B. *Fls. whitish or yellowish, all complete.*

1. **hírta,** Ell. Erect, 2–4 ft. tall, silky-pubescent: petioles shorter than the lvs.; lfts. nearly orbicular to long-ovate: fls. in oblong or cylindrical heads on peduncles that usually exceed the lvs.: pod scarcely shorter than calyx, oblong-ovate, pubescent. Dry soils, New England to Fla. and West. Mn. 6:181.—There is a form with oblong lfts.

2. **capitàta,** Michx. Much like the last, but petioles very short, lfts. narrow-oblong or oval, and the fl.-heads dense and short-peduncled (peduncles shorter than lvs.). Range of the above.

BB. *Fls. purple or violet, or some of them apetalous.*

C. *Peduncles slender.*

3. **violàcea,** Pers. Two to 3 ft., only sparsely leafy and slightly pubescent: lfts. broad-oval or oblong: fls. small, in a loose cluster which is on a stalk usually longer than the lvs.: pod ovate. Dry places N. H., west and south.

4. **Núttallii,** Darl. Two to 4 ft., villous: lfts. oval, oblong or nearly orbicular: fl.-clusters dense or even capitate, the stalk mostly exceeding the lvs.: pod oval. New England, west and south, in dry soil.

CC. *Peduncles nearly or quite wanting.*

5. **Stûvei,** Nutt. Mostly unbranched, 2–4 ft., very leafy, velvety-pubescent: petioles very short; lfts. elliptic, firm, woolly or velvety both sides or at least underneath: fls. in nearly sessile, axillary clusters or heads. Vt., south and west.

6. **frutéscens,** Brit. (*L. Stùvei* var. *intermèdia,* Wats.). Less pubescent or almost glabrous: petioles mostly longer; lfts. oval or oblong: clusters very short-stalked. Maine, south and west.

AA. *Oriental lespedeza, grown for forage in the S.: of trailing habit: stipules and fl.-bracts conspicuous.*

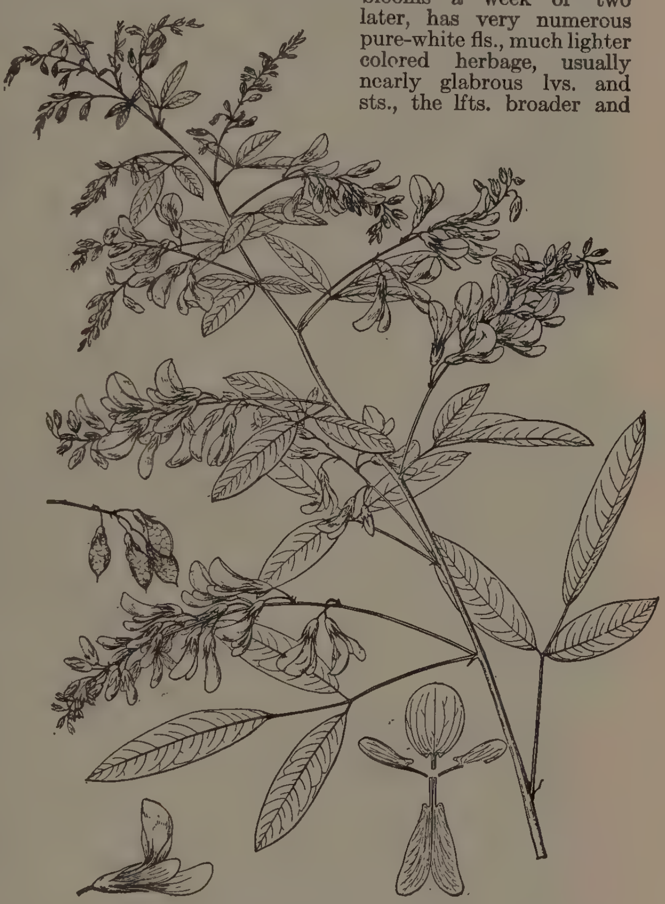
7. **striàta,** Hook. & Arn. JAPAN CLOVER. HOOPKOOP. Annual, somewhat pubescent, decumbent or erect, slender: lvs. small and very numerous, the lfts. oblong or obovate, and the petioles very short: fls. small, pink or purple, in axillary clusters. China and Japan.—The date of introduction to this country is not known; it was collected in Georgia in 1846. It is now extensively naturalized south of Washington and the Ohio River, growing on nearly all kinds of land. On light lands it makes dense mats, but on heavy lands grows 18–24 in. high. It is a good pasture- and hay-plant, and is useful for plowing under as a green-manure. It thrives on land which is indifferently prepared. Seed is sown early in spring, at the rate of 15–25 lbs. to the acre. It often yields 2 tons and more of hay to the acre. For pasturage in the S., it is sometimes sown with oats in the autumn.

AAA. *Oriental lespedezas, grown as ornamental plants for the fls.: erect: stipules and fl.-bracts small: perennials.*

8. **bícolor,** Turcz. Fig. 2134. Shrub, with slender branches, becoming 6–10 ft. tall, slender and graceful, glabrous: lvs. on thin wiry stalks, mostly longer than the glabrous blades; lfts. oval to round-obovate, rounded at the apex, the terminal one 1–2 in. long: fls. small, purple, in simple or compound racemes, which surpass the lvs.: pod ¼in. long, somewhat pubescent. Japan. G.F. 5:114 (where *L. bicolor* and *L. Sieboldii* are contrasted by J. G. Jack, and drawn by Faxon, and here reduced in Figs. 2134, 2135).—Hardy as far north as Boston, blooming in July and seeding freely. A white-fld. variety is advertised.

9. **Sièboldii,** Miq. (*Desmòdium penduliflòrum,* Oudem. *L. racemòsa,* Dipp. *L. formòsa,* Koehne. *L. bícolor* var. *Sièboldii,* Maxim.). Fig. 2135. Herb (shrub in warm regions), throwing up strong, wiry shoots each year from the crown: sts. angled, reddish or brown, hairy (at least above): lvs. dull above and light-colored and hairy beneath, the petiole usually somewhat shorter than the blade; lfts. elliptic-oblong-pointed: fls. twice larger than in the last (nearly ½in. long), rose-purple, drooping in very numerous long racemes, which at the top of the plant are panicled: pod nearly or quite ½in. long, pubescent. Japan. G.F. 5:115. Gng. 1:23. R.H. 1873:210. J.H. III. 30: 15. G.C. II. 20:749. F.S. 18:1888. B.M. 6602 and Mn. 7, p. 69 (as *L. bicolor*).—Blooms in Sept. and hardy in Cent. New England. A very desirable late-blooming plant, making a large specimen with age. Does not often seed in the N.

10. **japónica,** Bailey (*L. Sièboldii* var. *albiflòra,* Schneid. *Desmòdium japónicum,* Hort., not Miq.). Very like *L. Sieboldii* and perhaps a form of it, but blooms a week or two later, has very numerous pure-white fls., much lighter colored herbage, usually nearly glabrous lvs. and sts., the lfts. broader and less pointed.—Hardy as the last, and seems to seed more freely in the N.



2135. Lespedeza Sieboldii. (×½)

Other Japanese and Chinese lespedezas may be expected to appear in the trade. See Franchet, R. H. 1890, pp. 225–227, for an account of W. China ornamental species, with picture of *L. Delavàyi,* Franch., which grows 3–6 ft. high, with elliptic obtuse lfts., and deep violet to purplish black fls. in a terminal panicle.—*L. cyrtobótrya,* Miq. Shrub, to 6 ft. or more, glabrous or somewhat pubescent, with the habit of L. bicolor but less handsome: lvs. of the shoots long-stalked, oval to oval-oblong, rounded or slightly emarginate at the apex, 1–1½ in. long, the middle lft. long-stalked: lvs. of the lateral flowering branchlets short-stalked, crowded and much smaller; lfts. all short-stalked, oval, emarginate, ⅓–¾in. long: fls. purple, ⅓in. long, in dense axillary clusters or racemes not exceeding ½in. length. Japan.—*L. macrocárpa,* Bunge (Campylobotrys macrocarpa, Rehd. Campylobotrys chinensis, Bunge). Shrub, to 6 ft.: lvs. long-stalked; lfts. oval to oblong, emarginate, glabrous above, silky-villous below, ¾–1½ in. long, the middle one long-stalked: fls. purple, ⅓in. long, slender-stalked in axillary many-fld. stalked racemes to 3 in. long: pods glabrous, more than ½in. long. N. and Cent. China.—*L. serícea,* Miq. Suffruticose, to 3 ft. high: lvs. crowded, rather short-stalked; lfts. short-stalked, linear-oblong to linear, rounded at the apex, ⅓–¾ in. long, strigose beneath, minutely so above: fls. white, nearly sessile, ¼in. long, in axillary dense clusters or in dense and short leafy racemes to 1 in. long: pod little over 1 line long. China, Japan.

L. H. B.

LETTSÒMIA (John C. Lettsom, 1747–1815, English physician and botanist). *Convolvulàceæ.* About 30 species of scandent shrubs of Trop. Afr. and E. Asia, which may occur now and then in collections in Fla. Allied to Argyreia, differing in ovary 2-celled rather than 4-celled: lvs. alternate, undivided: fls. mostly purple or rose-color, in cymes or heads; corolla tubular to funnelform, the stamens exserted or included: fr. an indehiscent caps.

capitàta, Miq. (*L. strigòsa,* Roxbg. *Convólvulus capitàtus,* Vahl. *Argyrèia capitàta,* Choisy). A beautiful vine with handsome lvs. and deep pink fls.: strong climber, with hispid branches: lvs. cordate-suborbicular, short-acuminate, somewhat hispid, 5 in. long: fls. hispid without, capitate on peduncles 2–4 in. long; corolla 2 in. long. India, Java. Grown in S. Fla.

L. H. B.

LETTUCE. The lettuce plant is botanically *Lactuca sativa* (which see), which is probably derived from *Lactuca Scariola.* It is an annual with milky juice, and has been greatly developed for its root-leaves. These leaves, much enlarged and modified, comprise the most popular of the plant salads. It has been in cultivation for more than 2,000 years, according to De Candolle. The varieties are many; in 1889, "Annals of Horticulture" listed 119 varieties offered by American dealers. The two general forms are the head lettuces and the cluster or open-leaf lettuces (Figs. 2136, 2137). There are also spring lettuces and summer lettuces, the latter being developed to withstand more heat, for lettuce usually thrives best in the cool weather of spring. Of late years, kinds specially adapted to forcing have been secured, as the growing of the crop under glass has now assumed large proportions. See *Forcing,* Vol. III, p. 1255.

2136. Heading type of lettuce.

The lettuce plant is quite hardy to cold, comes quickly to edible maturity, is not much subject to disease or insect injury and, though it quickly succumbs to dry hot weather, is generally of the easiest culture. Even a farmer's wife, who, because of household cares, cannot take the time to plant a garden or even to gather and prepare a mess of peas or beans, can make and care for a planting of lettuce, and a few heads cut in the early morning and placed where they will be kept cool are a most appetizing addition to the noonday meal. From 1 to 2 yards of row to a person should yield an abundance for as long as a single planting is usable and a family supply may be grown in the smallest village yard or even on the back of a city lot; and, because of coming to the table in better condition, may be superior to any obtainable from the market.

Hundreds of different varieties and strains have been developed, varying greatly in habit of growth and character or product, ranging from those with but a few upright-growing narrow, smooth, thin leaves, and which soon shoot to seed, to those with many thick broad, smooth, crumpled or savoyed leaves, either clustered together, or overlaying each other so as to form a round head like that of a cabbage.

Varieties differ greatly in adaptation to cultural conditions, some giving fine returns when grown under glass but are hardly usable when grown in the open garden. They also differ greatly in color, tenderness and other qualities of the leaf. In some varieties, like the Prize Head, the leaf is mottled with red and brown and so tender that they are often so broken and torn apart by a heavy rain as to be unsalable, while the light green more tender-looking but really tougher leaves of a nearby planting of Grand Rapids are uninjured. There are varieties that form very broad white midribs which, when the green portion of the leaf is cut away, make quite as beautiful salad for table decoration or to eat from the hand as the finest celery or witloof.

There are many forms of Cos lettuce that are seldom grown in this country because they do not thrive in our bright sunny days, but do much better in the cloudy weather of England, where our most popular American sorts are considered coarse and weedy. All varieties require for the best development well-drained but moist cool friable soil, and thrive best in cool moist weather. They cannot be grown to perfection in the heat of midsummer. Even more than with many vegetables, it is essential to the most successful culture of lettuce that the soil be well enriched from previous dressings rather than recent applications, and if only coarse and fresh manure is available that it be well shaken apart, evenly distributed through, and well mixed with the soil. The most experienced Boston growers hardly expect a full crop until after the second or third manuring. Hardwood-ashes and bone-meal usually prove the most profitable artificial manures. Plantings for the first crop can be safely made as early as the soil can be put in friable condition. In many lots of seed the outer seed-coats are very hard, resulting in slow germination, and it may be advantageous to soak the seed for twenty-four hours before planting. Drills about 16 to 24 inches apart and evenly about 2 inches deep should be made and while the soil is still fresh and moist twenty to forty seeds to the foot should be evenly distributed and covered with not to exceed ½ inch of fine earth. Any greater depth, particularly on heavy soils, lessens the chances of a good and even stand. Some varieties are more sensitive than others to deep covering. Many successful growers in planting the Grand Rapids do not cover the seed at all except by washing over a little earth with a watering-pot and then shading with a board supported 1 or 2 inches above the row and removed as the plants germinate and start into growth. As the plants appear they should be thinned so as to prevent crowding and replanting should be made every fifteen to thirty days in order to secure a succession. With common facilities it is impossible to grow good lettuce in the dry heat of midsummer, though plantings in early autumn often furnish that of the very best quality.

In villages, plantings of lettuce for sale in the immediate vicinity often prove very profitable, the great essential to success being a rich well-drained soil, the

LXIV. A good field of lettuce.

2137. Clustering type of lettuce.

use of good seed of a suitable variety, the gathering of the crop in early morning when the leaves are cool and stiff and handling it with as little exposure to sunshine as practically possible.

In the recent years, hundreds of acres from Washington southward have been devoted to growing lettuce for shipment during the late winter and spring. In the northern sections, sash-covered frames with a single hot-water pipe along the front to guard against severe freezing are used. Farther south similar frames without provision for artificial heat but covered during the colder nights with sash and mats are used, and still farther south frames with only canvas curtains; or the crop is grown in sheltered fields with no artificial protection. All such plantings, however, are liable to become unpalatable or even killed by long-continued cold. The great essentials to success are a rich soil, even moisture, the fullest possible exposure to sunlight and first of all the use of pure seed of a variety like the Hubbard Market which is hardy and adapted to that cultural method and will stand shipment long distances and exposure in the market without loss of attractiveness.

The growing of lettuce seed.—In few vegetables is the satisfaction from a planting more dependent upon the varietal character and quality of the seed used, and fortunately the quality of most of that on the market is very dependable. Up to about 1865 most of the seed came from Europe, though comparatively small quantities were grown in Connecticut, New York and Michigan. About that time persons began to grow lettuce seed in California and the amount produced has increased until today not only the greater part of that used in America is grown there but large and constantly increasing quantities are sent to Europe. While small plantings of especial lots, of which little stock seed is available, are grown from started plants which are set in place in the field, the greater part of the crop is grown from seed sown in rows about 30 inches apart and the least typical plants pulled out until three to five plants to the yard are left. Many stocks grow such large and solid heads that they have to be pulled apart in order to let the seed-stalks shoot up, and often the lower leaves of the plant have to be pulled away to prevent the seed-stalk rotting at the base. As soon as the seed begins to ripen, the plants are cut and laid on large sheets onto which the earlier ripening seeds fall and the later ones are threshed off. The yield of seed varies greatly with the variety and the grower's success in securing it with little loss from birds or from shattering in the field and while harvesting, and commonly runs from 500 to 1,000 pounds to the acre. The growing of seed requires special experience and skill.

W. W. Tracy.

LEUCADÉNDRON (Greek, *white tree*). *Proteàceæ.* This genus includes the celebrated silver-tree of the Cape of Good Hope (see Fig. 2138), which has a striking and characteristic habit, and leaves densely covered with white silky hairs.

Shrubs or trees, all of S. Afr., above 60 in number: lvs. mostly narrow, sometimes even needle-like, entire, glabrous or silvery-tomentose, with a hardened apex: fls. diœcious, regular; male fls. usually many, in heads, each subtended by a bract and the head sometimes involucrate, the perianth-segms. separated to the middle or beyond, the anthers oblong or linear and sessile at the base of the perianth-limb; female fls. subtended by woody bracts and aggregated into cone-like heads, the perianth more deeply divided than that of the male fls., bearing narrow staminodia.

argénteum, R. Br. (*Pròtea argéntea*, Linn.). Silver-Tree. Fig. 2138. Branches densely leafy: lvs. sessile, 3–6 in. long, ½–1¼ in. wide, callous and blackish at the apex, lanceolate, acute, silvery white, and silky: involucres spreading, longer than the globular head of fls.: nut ventricose, turgid, wingless, the whole style and calyx persisting with it, obovate. B.R. 979. V. 5:282, 283. G.C. III. 6:725.—This tree grows wild on Table Mountain, Cape Town. In the early part of last century it was much used by settlers for firewood. It is said to grow poorly away from the Cape, except in S. Calif., where it does well outdoors. It is also rarely cult. in the E. in tubs, being protected in a cool greenhouse in winter and placed on the lawn in summer. The silver-tree attains 30 ft. at the Cape, and in S. Calif. it has reached more than that height but is reported to be short-lived (25–30 years at the most). It is a very showy plant because of its silky somewhat compact foliage, and is worth growing for the juvenile state. Not difficult to start from seeds, but seedlings are very liable to damping-off, and the plants are said to transplant with difficulty in Calif. The tree needs good drainage. The dried leaves are sometimes used for decorative purposes. (See G.C. III. 6:714).

L. H. B.

2138. Silver-tree.—Leucadendron argenteum.

LEUCÆNA (probably from Greek, *leukos*, white, referring to the flowers). *Leguminòsæ.* This genus includes a tree known in southern Florida as the white popinac, a rapid grower, with acacia-like foliage and whitish flowers; it is also cultivated in S. California.

Trees or shrubs, usually unarmed, evergreen: lvs. alternate, pinnate, stipellate: fls. usually perfect, in close heads, not papilionaceous, the 5 petals being separate; calyx 5-lobed; stamens 10, not glandular, exserted; ovary stalked and style filiform: pod flat, broad-linear.—Species 9 or 10. Mex., Guatemala, Peru, and Pacific Isls. The trees and shrubs of this genus have the habit of Acacia, but belong to the Mimosa tribe.

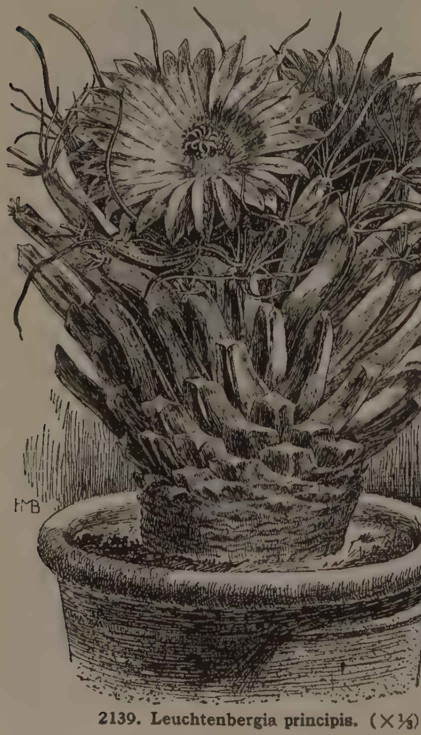
glaùca, Benth. (*Acàcia frondòsa,* Willd. *A. glaùca,* Moench. *A. leucocéphala,* Link. *Mimòsa glaùca,* Linn.). Spineless, tree reaching 30 ft. or more: pinnæ 4–8-paired; lfts. 10–20 paired, oblong-linear to lanceolate, oblique, glaucous below: heads of fls. globose, to 1¼ in. diam., white; petals erect, very narrow, about one-third as long as stamens: pod 5–6 in. long. Trop. Amer., but occurring in Fla. and Texas; naturalized widely in Old World.—It is cult. as an ornamental tree, and the young frs. and seeds are said sometimes to be eaten with rice; reported also to be used in certain regions as a forage plant for some animals.

L. trichòdes, Benth. (Acacia trichodes, Willd.). Tree-like: pinnæ 2–3 pairs; lfts. 3–5 pairs, ovate, acute: fl.-heads twin on axillary peduncles. S. Amer.

L. H. B.

LEUCÁNTHEMUM (*white flower*). *Compósitæ.* An old group-name for certain perennial herbs now included in Chrysanthemum. The most familiar species of the group is the common white-weed or "daisy" of the northeastern states, *Chrysanthemum Leucanthemum* (or *Leucanthemum vulgare* of former works). As distinguished from Chrysanthemum, the genus Leucanthemum differs chiefly in unimportant and inconstant characters of the achene.

LEUCHTENBÉRGIA (after Prince Leuchtenberg). *Cactàceæ.* AGAVE CACTUS. Stems in age forming a trunk 2 in. or more in diam., by the shedding of the lower tubercles: tubercles triangular-acuminate, spreading, 2–4 in. long, ½–¾in. wide, with twisted papery spines: fls. funnelform, widely expanded, borne near the apex of young tubercles: fr. gray, ovate-elliptical, 1 in. long, covered with scales and crowned by the persistent fl.; seeds dark brown, minutely tuberculate.—Only 1 species, closely related to Echinocactus, but of remarkably different form. The plant is readily grown in the manner of Echinocactus and Mamillaria.



2139. Leuchtenbergia principis. (×⅓)

príncipis, Hook. & Fisch. Fig. 2139 (adapted from Botanical Magazine.) Radial spines 6–8, the central one usually solitary, longer, sometimes 8 in. long: fls. yellow. B.M. 4393. A.G. 11:464.

KATHARINE BRANDEGEE.

LEUCOCÓRYNE (*white club,* alluding to the sterile anthers). *Liliàceæ.* About a dozen small bulbous plants of Chile, allied to Milla and Brodiæa, half-hardy in England, rarely planted here; they probably require the treatment given ixias. Plants scapose, with radical lvs., and tunicated bulbs or corms: fls. few, in terminal bracted umbels; perianth with 6 nearly or quite equal spreading oval-oblong or narrow lobes; stamens 6, of which 3 are perfect and the others reduced to staminodia: caps. membranaceous, 3-grooved, dehiscent. The species known to cult. are: *L. ixioìdes,* Lindl. One foot: lvs. about same length: fls. 4–6, white or pale blue. B.M. 2382 (as *Brodiæa ixioides*). B.R. 1293 (as *L. odorata*). *L. alliàcea,* Lindl. Six to 12 in.: lvs. very narrow, 6–8 in. long: fls. pale lilac, ¾in. long.

LEUCÓCRINUM (Greek, *white lily*). *Liliàceæ.* WHITE MOUNTAIN LILY. SAND LILY of Colorado. A bulbous plant growing a few inches high, with narrow foliage and clusters of pure white fragrant flowers borne just above the gound in early spring.

The fls. are funnel-shaped, having a slender tube 2–4 in. long, the greater part of which is below the surface, and 6 lobes, each ¾–1½ in. long, borne in clusters of 4 to many fls., and maintaining a succession for several weeks. They should be desirable for edging walks and bulb beds. They have a deep-seated rhizome and fleshy roots. The bulbs are procurable from Colo. and Calif., either as collected or nursery-grown stock. The genus has a single species. It belongs to an anomalous group, characterized by almost total lack of st. and fls. solitary or clustered among the radical lvs. From the other members of this group it is distinguished by the lvs. not 2-ranked, and an indefinite number of ovules in each locule. Perianth-segms. narrowly lanceolate, persistent; stamens 6; style persistent, slightly 3-lobed.

montànum, Nutt. Lvs. 8–12 or more, flat, rather thick, 4–8 in. long, 1–3 lines wide: pedicels ½–1½ in. long. Sandy soils and in mountain valleys, W. Neb. and S. Dak. to Colo., Ore., and N. Calif.

J. H. COWEN.

LEUCÓJUM (name discussed below). Also written *Leucoium. Amaryllidàceæ.* SNOWFLAKE. Hardy bulbous plants growing a foot or less high and bearing dainty, nodding, 6-parted flowers, which are white, tipped with green, yellow, or a tinge of red.

Perianth-tube none; segms. uniform, ovate or oblong, spreading; stamens epigynous; filaments filiform, shorter than the linear-oblong basifixed anthers; ovary 3-celled; ovules many in a cell, superposed; styles filiform or strumose near the apex; stigma minute, capitate: fr. finally dehiscing loculicidally into 3 valves from the top; seeds subglobose; testa usually black: rootstock a bulb, with membranous tunics: lvs. slender or lorate: fls. 1 or several in an umbel, white, tinged with red or green; spathe-valves usually single.—Eight species, natives of Eu. and the Medit. region, 6 of which are cult. The name Leucojum was given by Linnæus, but he did not explain the application. The old Greek name, *Leuccion,* was given by Theophrastus to a plant now supposed to be a crucifer, like some stock or wallflower. *Leucoion* is from *leukos*, shining, white, and *ion*, violet. Parkinson called it the "great early bulbous violet." Snowflakes appear about the same time as white violets, and sometimes have a delicate odor, resembling that of the violet.

Leucojums are best planted in dense groups, and allowed to remain undisturbed for a number of years. When bulbs are procured in the fall, plant immediately. Suitable for border, rock-garden or grass. Plant in a well-drained soil about 3 inches deep. Give a good winter protection. They are less popular than snowdrops (Galanthus), to which they are closely related, and have larger fls., with all the segms. of equal size.

A. *Blooming in March to early April.*

vérnum, Linn. (*Erinósma vérnum*, Herb.). Spring Snowflake. St. Agnes' Flower. Bulb globose, ¾–1 in. diam.: lvs. strap-shaped, finally 6–9 in. long, 4–6 lines wide: scape ½–1 ft. long, usually 1-fld.; perianth-segms. white, tipped green: seeds with a pale, membranous coat and conspicuous strophiole: fls. appear 1 month later than snowdrop. Cent. Eu., France to Bosnia and Tyrol. B.M. 46. G.C. II. 11:399; 21:341; 23:341. P.G. 5:47. Gn. 25, p. 335; 29, p. 607. V. 8:69. Var. **carpàthicum,** Herb., has perianth-segms. tipped yellow. B.M. 1993. J.H. III. 32:169. G.M. 39:105. A choice form, usually bearing 2–4 fls. Var. **Vàgneri,** Stapf. Early-flowering, with scapes usually bearing 2 fls. of which the green spots are of a darker shade. Hungary.

AA. *Blooming in April and May.*

æstìvum, Linn. Summer Snowflake. Bulb ovoid, 1–1½ in. diam.: lvs. strap-shaped, 1–1½ ft. long, yellowish green: scape 1 ft. long, 4–8-fld.; perianth-segms. white, tipped green: seeds with a black, hard-shelled coat and no strophiole. Cent. and S. Eu. Mn. 9:45. P.G. 1:7. V. 3:342; 8:70. G. 5:185; 25:222. J.H. III. 55:253.

pulchéllum, Salisb. (*L. Hernándezii*, Cambes.). Differs from *L. æstivum* by its smaller fls. and caps., narrower lvs. and fls. a fortnight earlier. Sardinia and Balearic Isles. Var. **màjus** is a selected large-fld. form.

hyemàle, DC. Bulb globose, under 1 in. diam., with several membranous brown tunics: lvs. 2–4, contemporary with the fls., erect, narrow-linear, glabrous, 6–12 in. long: peduncle slender, erect, 1–2-fld.; perianth white; segms. oblong, imbricated, tinged with green on back and laxly many-veined, the 3 inner shorter and rather more obtuse than the 3 outer; stamens bright yellow, styles rather short: seeds black, punctate, furnished with a conspicuous fleshy white caruncula. Maritime Alps. B.M. 6711.—Blooms in April, rather than in winter as the name would imply.

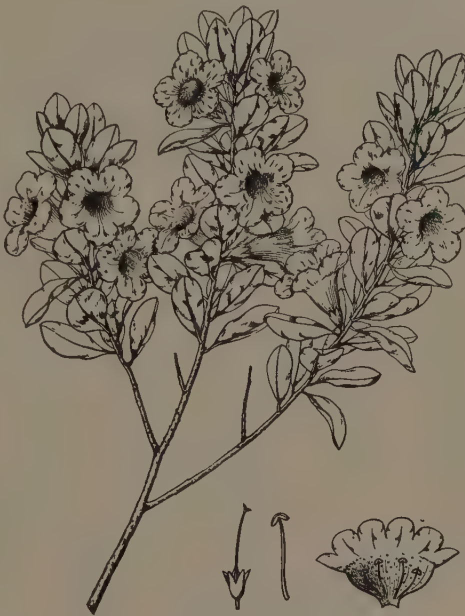
AAA. *Blooming in autumn.*

autumnàle, Linn. (*Àcis autumnàlis*, Salisb.). Autumn Snowflake. Bulb globose, ½in. diam.: lvs. thread-like, usually produced after the fls.: scape very slender, 3–9 in. long, 1–3-fld.; perianth-segms. white, tinged with red; stamens half as long as segms. Portugal and Morocco to Ionian Isls. B.M. 960.—Not satisfactory in northern gardens. Prefers a sandy soil.

ròseum, Martin. Bulb globose, ¼–½in. diam.: peduncle shorter and usually 1-fld.; perianth-segms. ⅓in. long, rose-red, oblanceolate; stamens ⅙in. long. Corsica.—Usually difficult to grow, and little known horticulturally.

Wilhelm Miller.
A. C. Hottes.†

LEUCOPHÝLLUM (Greek, *white leaf*). *Scrophulariàceæ.* Three spreading shrubs in Texas and N. Mex. with small alternate, elliptic to obovate entire lvs. covered beneath with silvery white wool: fls. axillary; calyx 5-parted; corolla campanulate or funnelform, with 5 rounded spreading lobes; stamens 4, didynamous, included, fixed at the base of the corolla; ovary 2-celled: caps. 2-valved; seeds many, oblong, wrinkled. Only the following species is cult. in S. Fla., and deserves cult. everywhere in the S. According to C. S. Sargent, "There is no shrub of the desert portions of the valley of the lower Rio Grande more generally distributed, and certainly there is not one of them which more delights the traveler in the early spring months, when the large, violet-purple flowers of this plant heighten the effect of its brilliant silvery foliage." G.F. 3:488.



2140. Leucophyllum texanum. (×½)

texànum, Benth. Fig. 2140. Loose-growing, straggling shrub, 4 or 5 ft. high in the wild, 8–10 ft. high in cult.: lvs. ½–1 in. long, obovate, narrowed to the nearly sessile base: fls. violet-purple, campanulate, 1 in. long and as much across, hairy within. Spring and summer. G.F. 3:489 (adapted in Fig. 2140).

Alfred Rehder.†

LEUCÓPHYTA (*white plant*, a Greek compound). *Compósitæ.* One species, **L. Bròwnii,** Cass., is offered abroad among coolhouse plants and is used in carpet-bedding for the white herbage. It is a much-branched rigid little white-woolly shrub (about 1 ft. high) from Austral.: lvs. alternate, linear, obtuse, very short and small (seldom ⅙in. long): heads small and collected in globular clusters ⅓–½in. diam., the clusters surrounded by a few floral lvs.: pappus of 8–10 plumose-ciliate scales which are slightly united at the base. The plant is of easy cult.; prop. by cuttings. It may be wintered in a frame or coolhouse.

The genus Leucophyta, with its single species, is usually united with Calocephalus, the above plant then becoming *C. Bròwnii*, F. Muell. The two genera were founded by Robert Brown at the same time (Trans. Linn. Soc. XII:106), but Calocephalus occurs first on the page. He separated Leucophyta because it differs in having a general involucre consisting of a few short bracts, in having the scales of the partial involucres concave and bearded at top, and in the pappus being plumose throughout its entire length.

L. H. B.

LEUCOSTÈGIA (Greek, *white roof;* alluding to the indusia). *Polypodiàceæ.* A small group of Indian ferns of small stature allied to Davallia, the indusium small, narrow, thin, attached by its base, with the apex and sides free. The lvs. are mostly tri-quadripinnate. For cult., consult *Davallia.*

pârvula, Wall. Rootstocks wide-creeping, scaly: lvs. nearly sessile, deltoid, less than 1 in. long, half as wide, usually tripinnate. Singapore and Borneo.

L. M. UNDERWOOD.

LEUCÓTHOË (*Leucothoë;* daughter of Orchamus, king of Babylonia). Including *Agarísta. Ericàceæ.* Ornamental shrubs grown chiefly for the handsome rather large usually evergreen leaves and the white flowers.

Evergreen or deciduous: lvs. alternate, short-petioled, serrate: fls. in axillary or terminal racemes; calyx 5-parted, imbricate; corolla ovate or cylindrical; stamens 10; anthers obtuse or 2-awned or 4-awned at the apex: caps. 5-lobed, with the sutures not thickened, separating into 5 valves; seeds minute, irregular. —About 35 species in N. and S. Amer., Madagascar, Himalayas and Japan, formerly often united with Andromeda, which differs like Lyonia chiefly in its valvate calyx.

The leucothoës, and particularly the evergreen species, are very handsome shrubs with rather large lustrous leaves and with white, rarely pink or scarlet, usually nodding flowers, appearing mostly in spring. The South American species, which are very rare in cultivation, though they surpass the others in beauty of the flowers, are hardy only South, while the other species can be grown as far north as Massachusetts and western New York, the evergreen ones in sheltered positions or with slight protection during the winter. They are very handsome for borders of shrubberies or as undergrowth in open woods. They thrive best in somewhat moist peaty or sandy soil, and prefer shaded or partly shaded situations, but also grow in full sun if the soil is not too dry.

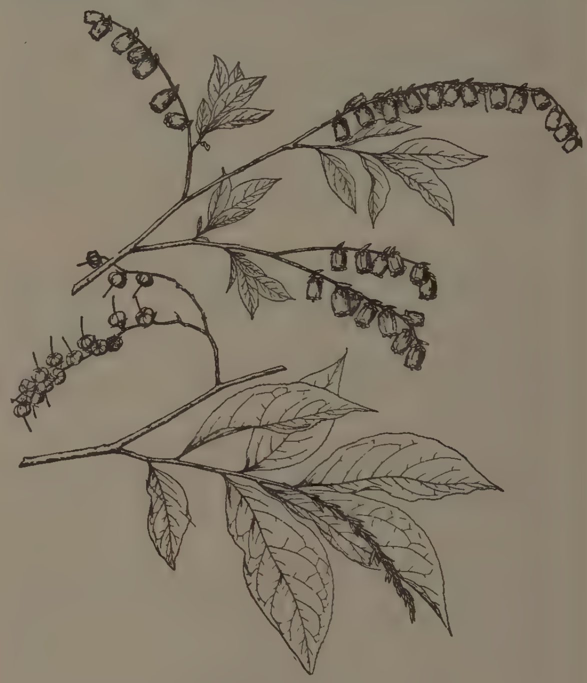
Of the leucothoës, *Catesbæi* is one of the most ornamental and popular hardy broad-leaved evergreens. It is used for massing in connection with rhododendrons, kalmias, and the like, serving as a base for these taller plants. The shiny dark green leaves are borne with regularity on a recurved stem often 2 to 3 feet long, and sometimes color brilliant bronze and claret shades in autumn when exposed to the direct rays of the sun. Leucothoë sprays are largely used by florists in making up designs and in connection with galax leaves, usually, however, in the more informal pieces. They were introduced to the trade about 1890. The fragrant flowers are in the leaf-axils, borne along the stem in early spring, and are usually conspicuous, considering the fact that the leaves are persistent. It is this graceful evergreen spray effect, with the good color and dense habit, that makes leucothoë so desirable as a plant for massing, and also the fact, perhaps, that it is fairly easy to transplant. Seeds are produced freely, and can be sown in sphagnum moss and sand under glass, as rhododendrons and azaleas are grown, pricked off in flats and planted outdoors in early spring, when the plants are a few inches high. Leucothoë is also propagated by division, underground runners and cuttings, the latter being plunged in sand on the bench and given moderate bottom heat. It is usually collected, however, in its native habitat, in small plants, transplanted to nursery rows and grown for several seasons. (Harlan P. Kelsey.)

A. *Lvs. evergreen: racemes axillary, sometimes clustered, shorter than the lvs.; anthers awnless.*

B. *Racemes dense, sessile, many-fld.: pith of branches solid.*

axillàris, Don (*Andrómeda axillàris,* Lam.). Shrub, to 5 ft., with spreading and usually recurving branches, puberulous when young: lvs. with short pubescent petioles, oval to oblong-lanceolate, shortly acuminate, serrulate toward the apex, glossy above, pale and sparsely pubescent beneath when young, 2–4 in. long: racemes 1–2 in. long; sepals broadly ovate; corolla white, usually greenish in bud, ⅕in. long. April, May. Va. to Fla. and Ala. G.O.H. 114. B.B. (ed. 2) 2:687. G.W. 6, p. 279. Var. **longifòlia,** Pursh. Lvs. linear-lanceolate. B.M. 2357.

Càtesbæi, Gray (*Andrómeda axillàris,* Michx. *A. Càtesbæi,* Walt.). To 6 ft., similar to the former, with glabrous, slender and more arching branches: lvs. longer-petioled, ovate-lanceolate to lanceolate, ciliately appressed-serrate, glossy above, usually light green beneath, glabrous, 3–7 in. long: racemes larger; sepals narrower; corolla over ¼ in. long: white, usually reddish in bud. April, May. Va. to Ga. B.M. 1955. L.B.C. 14:1320. R.H. 1905, p. 577. G. 34:487. Gn.M. 2:18. —This species is handsomer than the former, and also somewhat hardier: lvs. and fl.-buds assume a beautiful purple hue late in fall which is retained through the winter.



2141. Leucotnoë recurva. (×½)

BB. *Racemes peduncled, with rather few, slender-pedicelled fls.: pith lamellate.*

populifòlia, Dipp. (*L. acuminàta,* Don. *Andrómeda acuminàta,* Ait. *A. populifòlia,* Lam.). Shrub, to 12 ft., with spreading branches: lvs. short-petioled, ovate-lanceolate, acuminate, entire or obscurely serrulate, glabrous, 2–4 in. long: pedicels as long as corolla; calyx very short; corolla cylindrical, over ⅓in. long. June. S. C. to Fla.

AA. *Lvs. deciduous: racemes mostly terminal, secund, longer than the lvs.; anthers awned.* (*Subgenus Eubotrys.*)

racemòsa, Gray (*Andrómeda racemòsa,* Linn. *L. spicàta,* Don. *Lyònia racemòsa,* Don). Shrub, to 10 ft., with mostly erect branches: lvs. oblong to ovate, acute, serrulate, pubescent beneath, at least on the veins, 1–3 in. long: racemes erect, 2–4 in. long; corolla cylindrical, ⅓in. long; anthers with 4 awns. April–June. Mass. to Fla. and La. Em. 423. G.O.H. 57.

recúrva, Gray. Fig. 2141. Similar to the last, but lower and more spreading: lvs. elliptic-ovate to elliptic-lanceolate, acuminate: racemes spreading and recurved; anthers with 2 awns: caps. depressed and strongly lobed. April–June. Va. to Ala. G.F. 9:225 (adapted in Fig. 2141). I.T. 1:40.—It grows in drier situations; the foliage of this and the preceding species assumes a splendid scarlet color in fall.

L. Dàvisiæ, Torr. Evergreen shrub, to 5 ft.: lvs. oblong, obtuse, crenately serrulate: racemes slender, many-fld., clustered in terminal panicles. May, June. Calif. B.M. 6247.—*L. Grayàna*, Maxim. Half-evergreen: lvs. large, broadly oval, appressed-pilose: racemes terminal, slender; fls. rather small. June. Japan. Tender.—*L. neriifòlia*, DC. (Agarista neriifolia, Don). Evergreen, glabrous shrub, with ovate-oblong, acuminate lvs. and bright scarlet fls. in erect, slender racemes at the end of the branches. Brazil. B.M. 4593. J.F. 2:155.—*L. púlchra*, DC. (Agarista pulchra, Don). Evergreen shrub, 2 ft. or more high, glabrous: lvs. ovate, mucronate, about 1 in. long: fls. white, in spreading, peduncled, slender racemes, much longer than the lvs. Caracas. B.M. 4314.

Alfred Rehder.

LEÚZEA (De Leuze, friend of DeCandolle, who founded the genus). *Compósitæ*. A few perennial or biennial herbs with simple 1-headed sts., one of which is sometimes planted in herbaceous borders or rock-gardens. By some the genus is referred to Centaurea, becoming a section of that genus distinguished by the feather-like pappus in several rows and which is connate at base and falls as a ring. Plants unarmed: lvs. radical, or alternate if cauline, dentate or pinnatifid, white-tomentose beneath: fls. purple, in large and showy heads, the corolla regular or slightly oblique, the tube long and slender; style-branches very short; involucre ovoid or subglobose, the bracts in many series: heads homogamous.—Species probably 5 or 6, widely distributed; Eu., N. Afr., Austral.

conífera, DC. (*Centaurèa conífera*, Linn.). Small plant, 4–12 in. high, blooming in June and July, sometimes described as biennial and sometimes as perennial: lvs. lanceolate, tomentose beneath, entire or pinnatifid: involucre-scales glabrous: st. simple, 1-headed. S. Eu.

L. H. B.

LEVÍSTICUM (origin of name obscure; thought to be a corruption of Ligusticum). *Umbellíferæ*. Lovage. Perennial grown for its aromatic seeds, which are used in confectionary. The genus has only one species, and is distinguished by having a conspicuous involucre of narrow deflexed bracts, prominent involucels with connate bractlets, strongly ribbed fr. with solitary oil-tubes, obscure calyx-teeth, green-yellow petals, and large bipinnate lvs.

officinàle, Koch (*Hipposelìnum Levísticum*, Linn.). Lovage. Tall: lvs. dark green, shining; segms. wedge-shaped at the base, cut toward the apex: fr. 3-ribbed, hollow and boat-shaped or else flattish on one side, convex on the other. S. Eu., sometimes escaped in N. Amer.—The lf.-stalks were formerly blanched and eaten like celery. It is a tall, hardy perennial herb, with large, 2–3 times divided radical lvs. The plant may be prop. by seed sown as soon as ripe, but when plants are already established root-division is less troublesome and risky. Division may be made in the autumn, but better in the spring. The divided plants and the seedlings, when 2 or 3 in. tall, should be set in checks 3 ft. apart in deep, rich soil. When well established the plants remain profitable for many years, demanding but little attention.

L. H. B.

LEWÍSIA (named by Pursh for Capt. Meriwether Lewis, of the Lewis and Clark transcontinental expedition). *Portulacàceæ*. Fleshy-leaved low perennials, bearing showy white, rose or red flowers.

Plants acaulescent or nearly so, with thick and farinaceous caudex and root: lvs. narrow, mostly clavate or spatulate or oblong, entire, rosulate at the apex of the short caudex (or corm in one species): fls. 1 to many, on scapes, often large and handsome; sepals 2–8, persistent; petals 3–16; stamens 5 to numerous, the anthers oblong to linear; style-branches slender, 3–8, with long stigmatic surfaces: fr. a circumscissile caps.; several- to many-seeded.—Species about a dozen, from Colo., Wyo., and Mont. westward. The genus has been variously defined; as here characterized, it includes Oreobroma and species that have been described under Calandrinia and Talinum. From Calandrinia, the genus is separated by style-branches often more than 3, and caps. circumscissile near the base rather than 3-valved from the apex. The cultivator's interest in lewisias centers chiefly in *L. rediviva*, which is grown in collections of succulents. The other species are very little known as cult. plants, although there appears to be an accelerated interest in them in recent years. They should make good rock-garden and alpine subjects. See *Succulents*.

A. *Sepals, or sepal-like bracts, 4–8.*

1. **redivìva,** Pursh. Bitter-Root. Lvs. linear-oblong and nearly terete, densely clustered, glaucous and smooth: scapes little longer than the lvs., jointed at the middle where there are verticillate bracts; fls. rose-color or white. June–Aug. Mont. and north, to Ariz. and west.—It is the state flower of Montana. The bitter-root has an interesting history. It has been tested in the E., and is desirable for rockeries, needing perfect drainage, a sunny position and careful watering while in flower. It is one of those perennials that should be planted in groups for best effect, and also as a precaution to prevent loss by oversight in careless weeding during flowerless period. The starchy root is dug by the Indians in spring, and eaten. The bark is ordinarily very bitter, but at flowering time it is said to slip off easily, and the root when boiled has little of the bitter taste. The roots from which the plant was first described showed signs of life after being in the herbarium for several years. Pursh planted them, and they grew for a year. This event suggested the name *rediviva*. The fl. figured in B.M. 5395 came from a root which has been immersed in boiling water in order to make an herbarium specimen. The root is called spatulum or spatlum by the Indians. A full account of this plant is given by Pailleux & Bois in Le Potager d'un Curieux. Also in R.H. 1892, p. 298. B.M. 5395. V. 2:306. Mn. 2, p. 85.

AA. *Sepals 2, without subtending bracts.* (*Oreobroma.*)

B. *Root a small corm.*

2. **triphýlla,** Rob. Sts. slender, 1 to several from a globular corm ¼in. or less thick (differing from Claytonia in the circumscissile caps.), the plant 4 in. or less high: st.-lvs. 2 or 3, linear and sessile: fls. white, in an umbel of 3–20 or more, the scape partly underground. Subalpine, Colo., west and north.—Apparently not offered.

BB. *Root-part a more or less vertical caudex.*

C. *Lvs. narrowly linear.*

3. **mínima,** Nels. Lvs. few to several, 2 in. long, more or less, narrow-linear, usually exceeding the scape: fls. white; sepals about oval, with a short point and sometimes 1 or 2 lateral teeth; scape with a pair of small bracts toward the base. Yellowstone Park.—Offered in Colo.

CC. *Lvs. broader than narrowly linear, usually more or less spatulate (perhaps an exception in No. 9).*

D. *Scape 1–4-fld.*

4. **Tweèdyi,** Rob. (*Calandrìnia Tweèdyi*, Gray. *Oreobròma Tweèdyi*, Howell). Lvs. 2–4 in. long, obovate, mostly shorter than the 1–3-fld. scapes: fls pink, 2–3 in. across; sepals orbicular, entire: stamens

10 or 11: seeds granulate and arillate. Alpine, Wash. B.M. 7633. Gn. 59, p. 387; 64, p. 28. G.M. 46:335. G. 36:444. F.S.R. 1, p. 145.

5. **oppositifòlia,** Rob. (*Calandrìnia oppositifòlia,* Wats. *Oreobròma oppositifòlia,* Howell). Lvs. linear-oblanceolate to linear, 1–3 in. long, sometimes 1 or 2 pairs on the lower part of the scape: fls. 2–4, white or pale pink, on long pedicels; sepals roundish, denticulate at apex; stamens about 12. Calif., Ore.

6. **pygmæ̀a,** Rob. (*Calandrìnia pygmæ̀a,* Gray. *Oreobròma pygmæ̀a,* Howell). Lvs. broad-linear to spatulate or lance-oblong, mostly shorter than the scapes: fls. 1–2, rose-red; sepals somewhat truncate and erose; petals 6–8, and stamens about the same number. Alpine, Rocky Mts., Sierra Nevada, and Cascades.

DD. *Scape mostly several- to many-fld.*

7. **Cotylèdon,** Rob. (*Calandrìnia Cotylèdon,* Wats. *Oreobròma Cotylèdon,* Howell). Lvs. obovate-spatulate to orbicular, in a dense rosette: scapes several, to 10 in. high, bearing a panicle; fls. white, the 7–10 obovate or oblanceolate petals pink-veined down the middle; sepals roundish, denticulate; stamens 6–9. Mountains, N. Calif. B.M. 8220. G.C. III. 43:342; 49:337. Gn. 72, p. 290. G. 36:445.—Attractive, with its basal rosette and its red-lined fls. standing well above the lvs.; produces offsets.

8. **Hòwellii,** Rob. (*Calandrìnia Hòwellii,* Wats. *Oreobròma Hòwellii,* Howell). Lvs. oblong to ovate, flat, with thin crisped margins, forming a rosette: fls. deep rose-color, in short racemose cymes; sepals orbicular to broad-ovate; petals 7–10, oblong-lanceolate, emarginate or entire; stamens 7. S. W. Ore. G.C. III. 51:349. Gn. 78, p. 400. G. 36:445.

9. **Leàna,** Rob. (*Calandrìnia Leàna,* Porter. *Oreobròma Leàna,* Howell). Lvs. linear, somewhat terete, sometimes subspatulate, 1–2½ in. long, glaucous, tufted: fls. many, in a panicle, the scapes bearing a few scattered bracts; fls. red to white, with darker veins; sepals ovate or roundish, fimbriate; petals 5–7; stamens 4 or 5. Mountains, N. Calif., Ore.

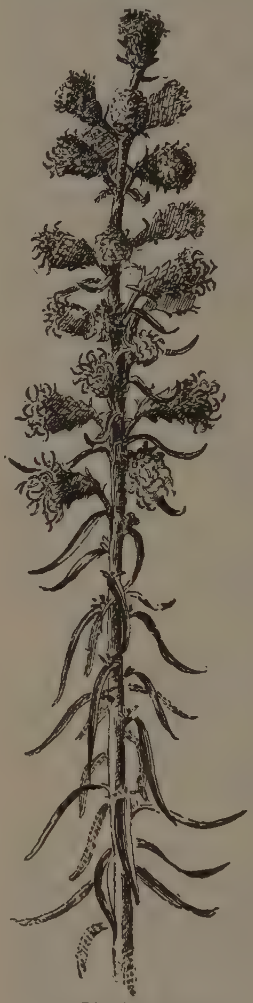
10. **columbiàna,** Rob. (*Calandrìnia columbiàna* and *Oreobròma columbiàna,* Howell). Lvs. numerous, linear-spatulate, flat, not glaucous, 1–2 in. long: fls. white or pink with dark red veins, few to many in a panicle; sepals rounded or truncate; petals 4–7, oblong, toothed, emarginate or entire. Columbia River and Cascades.
L. H. B.

LEYCESTÈRIA (Wm. Leycester, judge in Bengal). Including *Pentapýxis. Caprifoliàceæ.* Himalayan and Chinese small shrubs with whorled small flowers, suitable for mild climates.

Deciduous: lvs. opposite, simple, the stipules very small or none: fls. in erect or drooping verticillate leafy-bracted spikes; calyx persistent, unequally 5-lobed; corolla funnelform, nearly equally 5-lobed and swollen at the base; stamens 5, on the corolla-tube; ovary 5–8-celled, the stigma capitate: fr. a berry, sometimes eaten by birds.—Species about 4, only one of which appears to be in the trade; prop. by seeds and by cuttings. The genus is allied to Lonicera, from which it differs in its nearly regular corolla, and fr. with more locules; and to Diervilla, which differs in 2-loculed caps.

formòsa, Wall. (*L. élegans,* Hort.?). Strong-growing, with fistular (hollow) branches, 6 ft.: lvs. broadly ovate to ovate-lanceolate, acuminate, entire or toothed, more or less puberulous beneath: fls. purplish, fascicled in whorls in drooping leafy spikes or spike-like racemes: fr. dark red, subglobose. Himalaya, 5,000–10,000 ft., to W. China. B.M. 3699. G.W. 7, p. 355. B.R. 25:2. M.D.G. 1908:330. Gt. 28, p. 181. R.H. 1857, p. 109. Grown in England and apparently in Calif. Var. **variegàta,** Hort., has variegated foliage. Var. **ròsea,** Hort., has rose-colored fls.
L. H. B.

LHÓTZKYA (Dr. John Lhotzky, botanical traveler in Australia. and elsewhere). *Myrtàceæ.* Heath-line Australian evergreen shrubs of 10 species, rarely grown under glass. Lvs. small, scattered or opposite, entire and rigid: fls. sessile or nearly so, solitary or in leafy heads, white, yellow, pink or purple; calyx with an elongated ribbed tube and 5 broad very obtuse lobes; petals 5, entire and spreading; stamens many, in several rows. *L. acutifòlia,* Lindl., has white or yellowish fls. and linear mucronate lvs. ⅓–½ in. long. *L. ericoìdes,* Schauer, has white or whitish fls. and slender short linear 3-angled lvs.: erect, nearly glabrous, the fls. being in fascicles midway of the leafy branchlets. B.M. 7753. *L. violàcea,* Lindl., has purplish fls. and oblong very obtuse short lvs.



2142. Liatris spicata var. montana. (×½)

LIÀTRIS (a name of unknown derivation). Syn. *Lacinària. Compósitæ.* Blazing Star. Button Snakeroot. Hardy perennials, confined to eastern and southern North America, best adapted to the wild-flower border.

They are erect often resinous herbs, simple or branched, and arising from a tuber: lvs. alternate, narrow, 1–5-nerved: fls. in racemose or spicate heads; receptacle flat, or slightly convex, naked; corolla regular, its tube slender and 5-lobed.—Twenty-five or more species.

The most showy are *L. elegans* and *L. pycnostachya.* All produce flowers in wand-like spikes or racemes, the petaloid coloring of the involucral bracts often adding to the effect of the usually bright rose-red or purple flowers. Their flowers are produced in late summer and autumn. They multiply by offsets from their corm-like base, or may be grown from seed, which should be sown in autumn. They will grow and produce flowers in poorer soil than most garden plants, but thrive best in good, rich garden soil, and require no special care. When grouped in masses they give best results. They are scarcely domesticated as yet.

A. *Involucre-bracts obtuse.*

B. *Heads hemispherical, ½–1 in. broad, 15–45-fld. and peduncled.*

1. **scariòsa,** Willd. St. stout, 1–5 ft. high: lower lvs. spatulate or oblong-lanceolate, 4–6 in. long, ½in. wide; upper narrowly lanceolate: heads large, numerous, in a relatively loose spike; involucral bracts often tinged with purple; fls. purple; pappus bristles minutely bar-

bellate. Throughout the U. S. and Canada, east of the Rocky Mts. B.M. 1709. B.R. 590 and 1654. G.C. III. 14:593. P.M. 5:27 (as *L. borealis*).—Next to *L. elegans* and *L. pycnostachya*, perhaps the most desirable species for ornamental purposes.

BB. *Heads oblong, 3–4 lines broad, 5–15-fld.*

C. *Bracts not punctate.*

D. *The heads sessile.*

2. **spicàta,** Willd. St. stout, rather tall, 2–5 ft., and very leafy: lvs. all linear, the lower larger and broader than the upper, which are gradually reduced to the linear-subulate bracts of the spike: heads 8–13-fld., ½in. long, closely sessile, and forming a dense spike from 6–12 in. long; involucral bracts rounded obtuse, with usually purplish margins. In the Atlantic and Gulf States, from Mass. to La. G.W. 14, p. 299. B.M. 1411.—Useful for low situations or along streams.

Var. **montàna,** Gray (*L. pùmila,* Lodd.). Fig. 2142. Lower, 10–20 in. high: lvs. broader, the lower ones ½–¾in. broad, and obtuse at apex: spike proportionately short and heads larger, the fls. blue-purple. Va. and N. C., in the mountains. L.B.C. 2:147.

DD. *The heads distinctly pedicelled.*

E. *Lvs. oblong-lanceolate, relatively short.*

3. **gràcilis,** Pursh (*L. pauciflosculòsa,* Nutt. *L. lanceolàta,* Bertol.). St. slender, 1–3 ft. high: lower lvs. oblong-lanceolate, upon distinct petioles, upper reduced to small linear bracts: heads in a loose raceme, 3–5-fld., purple; bracts of the involucre few and rather loose. Ga., Ala. and Fla.

EE. *Lvs. attenuate-linear, the radical 8–12 in. long.*

4. **tenuifòlia,** Nutt. (*L. lævigàta,* Nutt.). St. slender, 2–4 ft. high: lvs. without distinction of blade and petiole, only a line or two wide: heads in a strict raceme, a foot or more long, about 5-fld., purple; pappus strongly barbellate. N. C. to Fla.—Suitable for dry sandy borders.

CC. *Bracts punctate: heads peduncled.*

5. **graminfòlia,** Pursh. St. comparatively slender, 2–3 ft. high, striped with light green lines: lvs. ciliate toward the base, with scattered hispid hairs: spike less dense, often becoming racemose; head ½in. long; bracts of involucre punctate, rounded at the apex. Atlantic States, Va. to Fla.—Adapted to a light dry soil. Considered by some to be a mere form of *L. gracilis*

AA. *Involucre-bracts acute or mucronate.*

B. *Heads 15–60-fld., cylindrical or turbinate.*

C. *Bracts with lanceolate, spreading, rigid tips.*

6. **squarròsa,** Willd. St. stout, 6–20 in. high: lvs. linear and rigid, the lower elongated and grass-like: spike variable in length, bearing few to many heads, the larger heads 1 in. long; fls. bright purple; involucral bracts lanceolate, rigid, and usually bearing pointed tips, squarrose. E. U. S., as far west as Neb. and Texas. B.R. 948 is var. **intermèdia,** of this species.

CC. *Bracts with closely appressed, mucronate tips.*

7. **cylindràcea,** Michx. St. 1 ft. high: lvs. and spike as in last species: heads few, 16–20-fld.; bracts of involucre abruptly mucronate. Upper Canada to Minn. and Mo.

BB. *Heads 3–6-fld., oblong or narrowly campanulate.*

C. *Inner bracts much longer than the fls.*

8. **élegans,** Willd. St. 2–3 ft.: lvs. linear, the upper soon reflexed: spike dense and wand-like, 3–20 in. long; heads ½in. long; inner involucral bracts prolonged into spreading, petaloid appendages, which surpass the fls. and pappus; fls. and petaloid appendages purple, showy. Va., to Fla. and Texas. B.R. 267.—Especially adapted for dry sandy situations.

CC. *Inner bracts not longer than the fls.*

D. *Pappus bristles very plumose: bracts appressed.*

9. **punctàta,** Hook. St. stout, 10–30 in. high: lvs. and involucral-bracts punctate and rigid: spike long and wand-like, dense and leafy; heads 4–6-fld., the fls. purple, ¾in. long; bracts of involucre oblong, rather abruptly cuspidate, ciliate on its margins; pappus plumose. Sask. and Minn. to Texas and Mex.

DD. *Pappus bristles merely barbellate.*

E. *Involucral-bracts spreading.*

10. **pycnostàchya,** Michx. St. stout, 3–5 ft. high: lvs. crowded throughout, the lower lanceolate, the upper narrowly linear: spike densely fld. 5–18 in. long; heads about ½in. long, all sessile; involucre with squarrose tips acute, purplish; pappus copious, minutely barbellate. Ill. and Iowa, to Ark. and Texas. R.H. 1883:324. Gn. 55:238. G.W. 6:169.—One of the choicest and boldest species.

EE. *Involucral-bracts appressed.*

11. **Chápmanii,** Torr. & Gray. St. a foot or two high, strict and rigid, white-velvety: lvs. short, the lower oblong-linear, the upper small and awl-shaped: spike densely fld., often 1 ft. long; heads about 3-fld.; fls. large for the size of the head, purple; pappus grayish, the bristles minutely barbellate, about ½in. long. Fla.

L. ligulistylis, A. Nelson. St. 16–20 in. high: lvs. bright green, glabrous, the lower lance-oblong: heads few to several, in a long raceme; fls. 50–70, purple; exserted style-branches conspicuous, flattened, as long as corolla, light purple. Colo., Wyo. to Dakotas.

W. W. Rowlee.
N. Taylor.†

LIBÉRTIA (Marie A. Libert, a Belgian woman, who wrote on liverworts about 1820). *Iridàceæ.* Tender mostly white-flowered plants classed as bulbs and procurable from Dutch dealers.

Perennial herbs with a short creeping rhizome and long fibrous roots: lvs. linear, equitant: perianth without any tube above the ovary; segms. obovate, the 3 outer usually shorter, firmer and less showy than the inner, more or less green or brown; stamens inserted at the base of the segms.; filaments free or connate toward the base; ovules many, superposed: caps. small, leathery, loculicidally 3-valved; seeds 3-cornered.—The genus has 8 or 10 species, in Austral., New Zeal., Tasmania and Chile. Botanically it is near Diplarrhena, but in the latter the inner segms. are shorter than the outer ones and connivent. Libertia belongs in the same subtribe with the blue-eyed grass (Sisyrinchium), but in the latter case all the perianth-segms. are about equal in size. One species is blue-fld. The libertias should be acceptable outdoor subjects in the milder parts of the country. Prop. by division and seeds. They require plenty of moisture at the roots.

A. *Fls. white.*

B. *Clusters lax: pedicels longer than the bracts.*

pulchélla, Spreng. Lvs. not rigid, 3–6 in. long, entirely green: st. ½–1 ft. long: infl. of 1 or few clusters, which are 2–3-fld.; segms. ⅙in. long, nearly equal, white. S. Austral., Tasmania, New Zeal.

ixioìdes, Spreng. Lvs. 1 ft. or more long, with a broad pale midrib: st. 1–2 ft. long: infl. an ample panicle with numerous peduncled, 2–6-fld. umbels; inner segms. orbicular-cuneate, white, the outer shorter tinged greenish brown: caps. broadly oblong or obovoid, ⅓–½in. long. New Zeal.

grandiflòra, Sweet. Lvs. rigid, linear, 1–2½ ft. long, with pale midrib: st. 2–3 ft.: fls. rather larger than in *L. ixioides*, the inner segms. much larger and broader than the outer, white: caps. larger than in last, about the same shape. New Zeal. G.C. III. 43:2.—An excellent free-flowering plant.

BB. *Clusters dense: pedicels shorter than the bracts.*

formòsa, Graham. Lvs. rigid, 1–1½ ft. long: st. 2–3 ft. long: infl. of many sessile and many-fld. umbels; inner segms, obovate-cuneate, ½–¾in. long, white; outer segms. half as long and oblong, greenish brown; filaments connate toward the base: caps. globose. Chile. B.M. 3294. B.R. 1630. Gn. 45, p. 192 (fine habit sketch); 40, p. 441; 70, p. 175; 75, p. 545. G.M. 51:797; 55:92. G. 29:687.

AA. *Fls. blue.*

cærulêscens, Kunth. Lvs. linear, rigid, 12 in. or more long: st. 1–2 ft., with a few reduced lvs.: infl. 6 in. or less long, of very many umbels, each many-fld.; fls. blue; inner segms. ¼in. long, oblong, the outer much shorter and greenish brown: caps. globose, very small. Chile.

L. nívea, offered abroad, may be one of the white-fld. species above: described as having iris-like foliage and spikes of white fls.: 2 ft.

Wilhelm Miller.
L. H. B.†

LIBOCÉDRUS (*libas*, drop, tear, and *Cedrus;* alluding to the resinous character of the trees). Syn. *Heydèria. Pinàceæ.* Incense Cedar. Ornamental trees chiefly grown for their handsome evergreen foliage and good habit.

Branchlets flattened, rarely quadrangular, frond-like in arrangement: lvs. scale-like, with decurrent base, with or without glands: fls. monœcious or diœcious, terminal, similar to those of Thuya: cones oblong to ovate, with 4, rarely 6, woody scales, the lower pair sterile, small and short, the second one much larger and fertile, each scale bearing 2 long-winged seeds, the third pair, if present, connate into a woody septum.—Eight species in W., N. and S. Amer., Austral. and S. W. China. Allied to Thuya which differs chiefly in the more numerous cone-scales with 2 pairs fertile.

The incense cedars are of pyramidal habit, clothed with small scale-like leaves, and rather small, ovate or oblong cones. None of the species is quite hardy North, but *L. decurrens* thrives in the vicinity of the city of New York, and even in sheltered places in eastern Massachusetts. It is a valuable park tree, forming a symmetrical narrow pyramid, with bright green foliage. It is also an important timber tree, the wood being light, soft, close and straight-grained, is very durable in the soil, and is used for fencing, for shingles, for the interior finish of houses, and also for ship- and boat-building. The other species are hardy only South, and, though very ornamental trees, they are hardly cultivated in this country; they are all important timber trees in their native countries. The incense cedars thrive best in a well-drained soil, and prefer open situations; they are liable to lose their lower branches rather early. Propagate by seeds sown in spring; also by cuttings under glass in late summer or fall, which root rather slowly; sometimes grafted on thuya and chamæcyparis.

decúrrens, Torr. (*L. Craigàna,* Low. *Thùya Craigàna,* Murr. *T. gigantèa,* Carr., not Nutt.). White Cedar. Tree, to 100, occasionally to 200 ft., with erect or spreading, short branches, forming a rather narrow, feathery head: bark bright cinnamon-red: branchlets much flattened, bright green on both sides: lvs. oblong-ovate, adnate, with long decurrent base, free at the apex and acuminate, glandular on the back: cones oblong, ¾–1 in. long, light reddish brown; scales mucronate below the apex, a third connate pair separating the 2 fertile ones. Ore. to Calif. and W. Nev. S.S. 10:534. F.S. 9, p. 19. Gn. 29, pp. 266, 267; 60, p. 250; 75, p. 296; 78, p. 586. G.C. III. 36:284; 44:338. M.D.G. 1905:129.—In cult. the young trees are conspicuous by their bright and deep green foliage, while the trees in their native localities are mostly of a light yellowish green. Var. **compácta,** Beissn. Dwarf compact form of globose habit. Var. **glaùca,** Beissn. With glaucous foliage. Var. **aùreo-variegàta,** Schwerin. Foliage variegated with yellow.

L. chilénsis, Endl. Tree, to 60 ft., with compact, pyramidal head: branchlets much compressed: lvs. glaucous green, small, erect-spreading, obtuse, with a silvery line beneath: cones ovate-oblong, ½in. long. Chile. G.C. 1850, p. 439. R.H. 1867, p. 410. Gn. 30, p. 552.—*L. cupressoìdes,* Sarg. (L. tetragona, Endl.). Tree, to 100 ft., with compact, pyramidal head, sometimes shrubby: branchlets almost tetragonal: lvs. ovate or ovate-lanceolate, with slightly spreading and acute apex: cones ovate; scales with a large, curved spine on the back. Chile to Patagonia. G.C. 1850, p. 439. Gn. 30, p. 552.—*L. Doniàna,* Endl.=L. plumosa.—*L. macrólepis,* Benth. & Hook. Tree, to 100 ft.: branchlets compressed, green on both sides: lvs. acute, the lateral strongly keeled, the middle ones obovate, apiculate: cones obovate-oblong, 1 in. long, consisting of 6 truncate scales. W. China. Gn. 62, p. 183 (habit). G.M. 47:860. J.H. III. 57:91.—*L. plumòsa,* Sarg. (L. Doniana, Endl.). Tree, to 100 ft., with dense, pyramidal head: similar to the former, but lvs. larger, more closely set and more spreading, without any silvery line beneath: scales of the cone with a large, curved spine on the back. New Zeal. This species is the most tender of this genus.—*L. tetragòna,* Endl.=L. cupressoides.

Alfred Rehder.

LIBÒNIA: *Jacobinia; Libonia floribunda=J. pauciflora,* page 1715.

ĹICUÀLA (Molucca name). *Palmàceæ.* Showy, dwarf fan palms, grown for their peculiar habit and handsome foliage.

Stems solitary or in groups, never very tall, and usually slender: lobes of the lvs. long, wedge-shaped, plicate, truncate and variously lobed or split, deeply and irregularly divided, appearing but not truly peltate; rachis very short; ligule short; sheaths fibrous: fls. large, hermaphrodite, in a loose panicle which appears among the lvs.—Species 50 or more, from Trop. Asia to Trop. Austral. Allied genera in cult. are Brahea, Serenoa, Erythea, Pritchardia, Livistona, Trachycarpus, Rhapis. From these Licuala is distinguished by the carpels of the ovary 3-angled, slightly coherent; style single, filiform: albumen equable: embryo dorsal. Desirable in cultivation. G.C. II. 25:139.

2143. Licuala peltata.

Licualas are very handsome warmhouse palms of moderate growth, several species of which have been grown to some extent commercially. They delight in a tropical temperature and abundant moisture, and should also be shaded from strong sunshine in order to produce foliage of the deep, rich shade of green that is common to this genus. Some advise treating them as semi-aquatic. The most attractive species is *L. grandis,* which has been until recent years a costly species owing to its comparative rarity in cultivation. It is probably within twenty-five years that the first consignment of seeds of this species was received in America. The large fan-shaped leaves of licualas are somewhat tender and easily injured, which makes them of less value for house decoration, but as exhibition plants there are few palms more striking than *L. grandis* and *L. elegans. L. spinosa* and *L. peltata* are also well worth cultivation, though objection is sometimes found to the strong hooked spurs with which their leafstalks are armed.

Propagation is by fresh seeds, over brisk bottom heat, preferably in pans. (W. H. Taplin.)

A. *Lvs. with lobes more or less grown together; lobes very broad.*

B. *Marginal teeth very large, the upper edges bent under.*

Rúmphii, Blume. Not unlike *L. spinosa,* but the petiole spiny below: segms. 12–15, the inner ones 2 ft. long and 1 ft. wide at the apex, the lateral ones 16 in. long and 4 in. wide, oblique; marginal teeth broadly ovate, obtuse, shortly bifid. Celebes and Borneo.—Cult. in S. Fla.

BB. *Marginal teeth with upper edges not bent under.*

grándis, Wendl. (*Pritchárdia grándis,* Bull). Erect palm, the sts. clothed above with dead sheaths: lvs. very many, erect-spreading; petiole 3 ft., slender, glabrous, with stout, short, straight or curved spines along the margins below the middle; blade orbicular or semi-orbicular, very closely plicate, wedge-shaped or truncate at the base, concave, the margins with many short lobes which are obtusely 2-fid; ligule thick, short, acute, broadly ovate. New Britain Isl., north of New Guinea. I.H. 28:412 and 41, p. 82. G.C. II. 1:415. B.M. 6704. A.F. 7:1145. F.E. 7:982. S.H. 1:344. G. 10:439. R.B. 37, p. 24.

AA. *Lvs. digitately divided; lobes narrow.*

B. *Lobes less than 12.*

Jeanénceyi, Sander. A dwarf, rapidly growing palm: lvs. deep shining green; lobes blunt, 5–8. New Guinea. Gn. 55, p. 71. F.E. 11:291. G.M. 41:341. A.G. 22:651.—This palm is known only in its sterile, young condition, and its relationship is in doubt. The name "Jeanenceyi" appears to be unknown in botanical literature. The plant is an attractive addition.

BB. *Lobes 12 or more.*

C. *Petioles without spines in the upper part.*

élegans, Blume. Sts. thick as a man's body, 4 ft. high, prominently scarred: petioles 3–4½ ft. long, the margins with brown hooked spines to just above the middle; lvs. orbicular; lobes very graceful, the linear-lanceolate lateral ones gradually decreasing to 11 in., obliquely truncate, with acute teeth, the middle lobes 16 in. long, truncate, with broader obliquely ovate obtuse teeth, lobes with only 2 or 3 folds. Sumatra.

CC. *Petioles spiny throughout.*

D. *Lvs. ascending.*

peltàta, Roxbg. Fig. 2143 (redrawn from Martius). Lvs. 3–5 ft. diam., orbicular; lobes very variable in length and width, many-toothed at the apex, the teeth ½–2 in.; petiole stout, 3–4 ft. long. The lobes of the lvs. droop very gracefully. India. G.C. 1872:1657.

ámplifrons, Miq. Lvs. 2½ ft. long, the tip ascending: blade usually about 12-parted, many of the divisions 2-lobed at the apex: spadix long and stiff, reddish brown: fls. and fr. unknown. Sumatra.—Not common in cult.

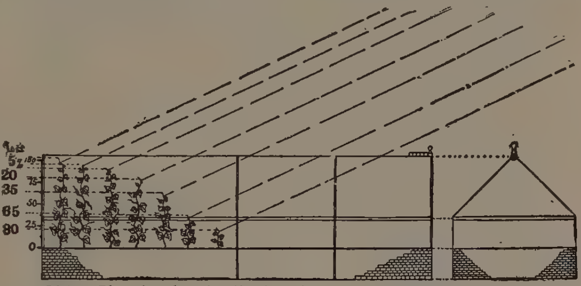
DD. *Lvs. horizontally spreading.*

spinòsa, Thunb. (*L. hórrida,* Blume). Lvs. 3 ft. or more diam., orbicular-reniform; inner lobes 18–22 in. long, 4½–5 in. wide at the apex, 10–11-toothed; outer lobes 15 in. long, 1½–2 in. wide, 4–6-toothed; teeth rather large, triangular-ovate, bifid; petioles obtusely 3-angled, 4–5 ft. long, with brownish hooked spines. Java, Moluccas.

JARED G. SMITH.
N. TAYLOR.†

LIDBÉCKIA (Eric Gustavius Lidbeck, Swedish botanist; published about 1750–1760). *Compósitæ.* Two S. African subshrubs or semi-herbaceous plants, sometimes grown in greenhouses and suitable for the open far S. Lvs. alternate, lobed or pinnatifid: peduncles 1-headed, the disk yellow and rays white; ray-florets neuter; disk-florets perfect, tubular; receptacle flattish; bracts of involucre in 2–3 series: achene glabrous, wingless and without pappus but crowned by a cylindrical nectary. Prop. by seeds when procurable, and by cuttings. *L. lobàta,* Thunb. (*Cótula lobàta,* Hort. *C. quinquéloba,* Linn. f.), is silky villous, 1–2 ft. high: lvs. petiolate, 3–5-lobed, the lobes broad-oblong and mucronate: involucre very hairy. *L. pectinàta,* Bergius, is glabrate or sparingly pubescent, 2–3 ft. high: lvs. nearly sessile, oblong, pinnatifid, glaucous beneath: heads larger than in the last, resembling *Chrysanthemum Leucanthemum,* the peduncles 1–3 in. long.

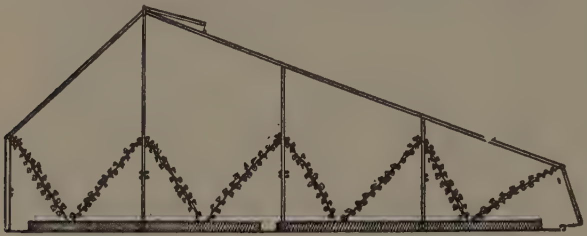
LIGHT. The various manifestations of energy which we term heat, light, electricity, gravitation, and the like, play an important rôle on living matter, and none is more important than light. Photosynthesis or carbon-assimilation, a characteristic plant function, constitutes one of the fundamental processes in nature; indeed this process, which in remote ages may have been developed secondarily as a protoplasmic function, is as wonderfu as life itself, and a thorough comprehension of photosynthesis would appear to be as difficult as that of life. However, no form of energy affects plant configuration more than light, and in the growing of crops, whether out-of-doors or in the greenhouse, the factor, light, must always be given consideration.



2144. Showing longitudinal and cross sections of a greenhouse with partitions running north and south, and illustrating the effect of poor light conditions. The oblique lines represent the path of the sun's rays.

Light is regarded as a form of radiant energy and is composed of various wave-lengths of exceedingly small size. Those which are especially active in photosynthesis or carbon-assimilation in our common green plants are in the red half of the spectrum, while the blue-green pigment organisms (marine algæ, and the like) utilize the more highly refrangible rays of the spectrum. Briefly, photosynthesis is the building up of carbohydrates from carbon dioxide and water through the chemical action of light on the chlorophyll, and since plants obtain most of their energy by means of this process, it is not difficult to realize its fundamental significance and importance. The ultimate product of photosynthesis is starch, but the complex chemical changes taking place in chlorophyll grains through the action of light and the building of starch from carbon dioxide and water is not definitely known, and there are doubtless many intermediate steps.

In any examination of flora is found much variation and adaptability to conditions, the result of innumerable generations existing under varied conditions. The light conditions in one section differ greatly from those in another part of the earth, but it is known from actual observation that some plants require much more light than others for their normal development. Even in the same location, such as the tropics, remarkable differences may be found in the light requirements. Many tropical plants require little light, and even when grown in northern latitudes in conservatories they require shading throughout the year. Palms, geraniums and other plants will develop normally under far less light than such plants as the cucumber or lettuce, but the latter grow much more rapidly and may perhaps for this reason alone show the ill effects of poor light regardless of their photosynthetic requirements. Within certain limits, however, it can be stated that photosynthesis or carbon-assimilation is proportionate to light intensity, and furthermore, that growth and development are correlated with photosynthesis.



2145. Showing cross section of an east and west house, about 36 x 200 feet, showing method of growing cucumbers. The light is much superior in a house of this sort.

The relation between photosynthesis and light intensity may be shown by using strong contrasting photographic negatives on leaves exposed to sunlight. By specially treating the exposed leaves, a positive can be produced which will show that little starch was formed under the thicker portions of the negative, and more under the thinner portions; in other words, the formation of starch under such conditions would be proportional to the amount of light received by the chlorophyll grains through the negative.

The general effect of light on growth is to retard it, though Blaauw, McDougal and Vogt have been able to discover a stimulation of growth under certain conditions, while, on the other hand, lack of light or darkness accelerates growth. The yellow rays of the spectrum are more active in inhibiting growth than the violet rays, the latter having a similar effect on plants to that of lack of light. Plants grow the most in the night, the growth curve gradually rising during the night and falling in the daytime. While lack of light stimulates growth, plants grown entirely in the dark or under poor light conditions are abnormal. Etiolated plants, or those grown in the dark, are devoid of chlorophyll, possess thin stems, elongated internodes and very poorly developed leaves. The mechanical or supportive tissue is little developed, and such plants possess small power of resistance. Light, on the other hand, develops mechanical tissue and induces firmness of texture. Moreover, without light there may be no increase in the weight of dry matter, hence seedlings grown in the dark may increase in size, but lose weight from respiration or loss of carbon dioxide.

Light is a factor in the dwarfing of alpine and arctic plants and in the development of hairs on some algæ as a protection against too intense illumination. Some plants grown in a weak light fail to produce flowers. (Insects attracted by the warmth of the sun are more likely to visit flowers growing in sunshine than in the deep shade.) Many fungi (Pilobolus) do not produce fruiting bodies (sporangia) until they reach the light. Wiesner, who has made a thorough study of the light requirements of plants, has classified some of our common species as follows:

(*a*) Light-requiring: Alfalfa, red clover, wild carrot and so on.

(*b*) Light-loving: Dandelion, plantain, lychnis and so on.

(*c*) Indifferent: Blueberry, poet's narcissus, the common brake, and the like.

(*d*) Light-shunning: Forget-me-not, violet, anemone and the like.

(*e*) Light-fearing: Wild strawberry, water violet, and the like.

Wiesner found that the beech, for example, reaches its normal development in one-tenth part of the light intensity required by the larch and other sun-loving plants.

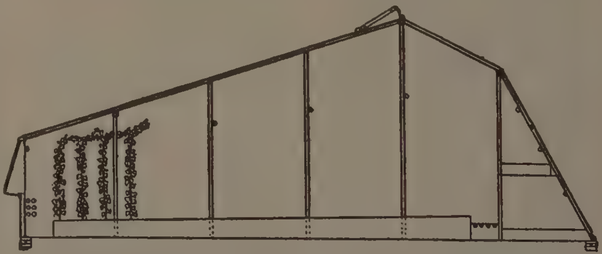
Light requirements are affected by a decrease in temperature: e.g., the maple in Norway requires ten times as much light as in Vienna for its normal development, and in general one may say, the farther north or the higher above sea-level a certain plant grows the greater becomes its light requirement.

The size of leaves is very much influenced by light. Too intense light as well as etiolation tends to reduce the size of the leaves, which reach their maximum in a medium light intensity. This is shown in the growth of such crops as cucumbers under glass during the winter.

Phototropism.

Phototropism or heliotropism is the term applied to the response of plants to a light stimulation from one side which causes movements toward or away from source of light. Phototropic movements are of much biological significance to the organism. Most aërial parts of plants (stems and branches) are positively phototropic, i.e., they bend toward the source of light, while roots are usually negatively phototropic, i.e., they bend away from light. For a clear understanding of the processes of plant response to light stimulation from one side, it is best to consider the reaction of a simple orthotropic plant such as the cotyledon of an etiolated oat seedling. This plant, which is remarkably sensitive, has been studied extensively by Darwin, Rothert, Fitting, Blaauw and others. It has been found in this plant that the apex of the cotyledon is the most sensitive to light stimulus, thus demonstrating, as in other forms of response, the localization of the perceptive or sensitive zone.

The bending toward the source of light as the result of the light stimulus begins at the apex, and it proceeds toward the base until the cotyledon coincides with the incident ray of light. The reaction time or latent period following stimulation is one-half to one hour in most cases, and the rate of transmission of the stimulus is from 0.7 centimeters to 1 centimeter an hour. The minimum time of exposure necessary to induce a reaction to a light stimulus is called the "presentation time," and this is dependent on the amount of light applied, which is a product of the light intensity, the exposure and distance from the plant. For example, an exposure to a light of high intensity (26,520 meter candle power) for one-thousandth of a second produced the same reaction as an exposure of forty-three hours to a light of very low intensity (0,00017 meter candle power).



2146. Showing cross section of a greenhouse used for lettuce and cucumbers. The slanting side toward the right (north) is boarded and used for forcing rhubarb. The cucumber plants are trained vertically.

An organ may be positively phototropic at one period of its development, and negatively phototropic at another, and it has been found that an oat seedling will respond positively and negatively or remain indifferent, depending upon the amount of light used. Many complicated forms of phototropism are observed in the movements of leaves and flowers (begonia and sunflower) which adjust themselves to certain angles as regards the source of light.

Phototaxis and photonastic.

The reacting or orientating response of motile (bacteria, swarm spores, and the like) or free-moving organs (chloroplasts) to a unilateral light stimulation is called phototaxis. This is a common mode of light reaction in plants. Plant movements which are not dependent upon the direction of light stimulus but are due to changes in the intensity are called photonastic movements. Under this category may be placed the movements of stomata which open under illumination and close in the darkness, also certain movements of etiolated seedlings when subjected to light.

The pathological effects of light.

The pathological effects of light on plants are a much more important factor than is generally realized. Many pathological conditions of plants are brought about by lack of light, and in some cases excess of light may produce injurious effects. This is shown in the case of sun-scald, which occurs on various trees. Some plants are so perfectly adapted to forest conditions that they cannot endure direct sunlight without injury. When they are exposed to direct light such as is caused by forest thinning, they are likely to sun-scald badly, but more often difficulties arise from lack of light. Tissue developed under poor light conditions is more likely to be affected with winter-killing due to non-ripening of the wood, and burning from fumigation with gases is induced by lack of light in poorly lighted greenhouses. Lack of light during the dark months often develops inferior tissue, which, when exposed to the more intense light of spring, becomes susceptible to wilting. The exclusion of light from part of the plants resulting from crowding, often gives rise to various stem-rots such as are characteristic of parsley, water-cress, lettuce, and the like, and there are a large number of leaf-blights and spots such as occur on cultivated plants which are induced by insufficient light. Lack of light induces the formation of various mildews on plants and is conducive to damping-off in many cases. It often causes disease of plants growing in dry soil as a result of excessive transpiration; in short, every greenhouse grower must regulate the growth of his crops according to light conditions in order to eliminate the possibility of disease.

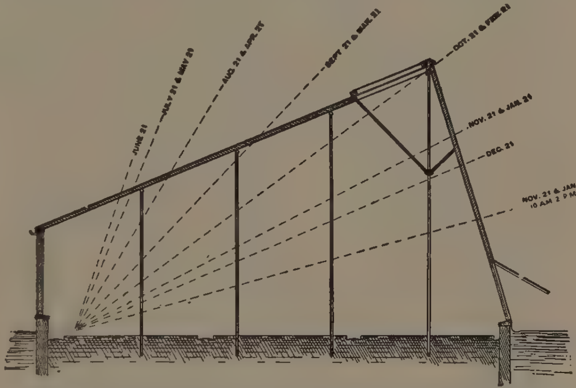
Light as a factor in greenhouse construction and management.

In the growing of plants under glass, which constitutes a large and constantly increasing industry, the problem of light is intimately associated with the location, construction of the greenhouses, management, and so on. Improvements in the line of greenhouse construction have been based very largely on the effects of light. The early houses in the United States were very crudely constructed, and in the modern, improved types of houses some crops are grown in one-half the time formerly employed, a fact due largely to improvement in methods of greenhouse construction. The old type of houses were chiefly sash-houses cumbered with shadow-producing material and glazed with small glass of inferior quality and often dirty, and widely lapped. The houses were in some cases so poorly constructed that they excluded from 40 to 60 per cent or more of light-rays. The modern house need not exclude more than 12 to 20 per cent. Some of the more or less modern types of houses which have been built for a number of years exclude as much as 30 per cent of light. Poor light conditions alone greatly retard growth, not to mention the frequent losses in poorly constructed houses from pathogenic organisms which find most favorable conditions for their development.

The amount of light to be found in any particular location depends upon the latitude, but more particularly upon the meteorological conditions which may prevail, and the variation in this respect throughout the United States is quite notable. Numerous meteorological observatories, without actually measuring the light intensity or amount of light, have given data as to the number of hours of sunshine, which is valuable in comparing light conditions in various localities. These records have been gathered for a considerable period of time and reliable averages are at hand. The average total number of hours of sunshine during the year based upon data covering a long period of time is as follows:

	Hours.
Chicago, Illinois	2,617
Cleveland, Ohio	2,000
Milwaukee, Wisconsin	1,865
Boston, Massachusetts	2,493
Nashua, New Hampshire	1,948
Ithaca, New York	2,273
New York, New York	2,510
Philadelphia, Pennsylvania	2,575
Phoenix, Arizona	3,742
Modena, Utah	3,354
Los Angeles, California	3,219

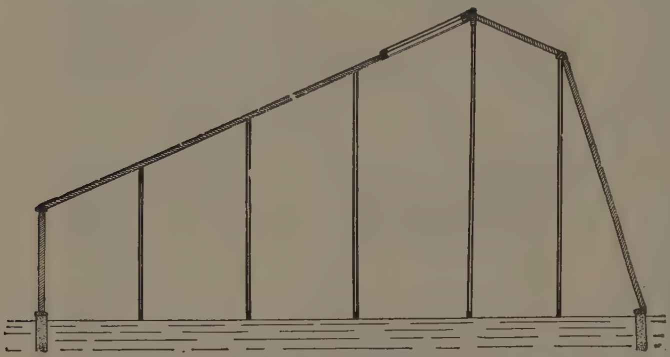
This data shows great variation in the hours of sunshine which cannot be attributed to latitude alone. It should be pointed out, however, that elevation constitutes a very important factor as regards light intensity, the higher the elevation the better the light conditions, and even the light intensities at an elevation of 500 to 600 feet are better than those at the surrounding low country, at least during the early parts of the day, but this difference gradually decreases toward night. From the commercial florist's point of view, the critical months in the year are November, December, January and February, and even a few days of cloudy weather when the crop is maturing often make much difference in the financial returns. Much more variation in light intensity exists in the dark winter months than in other seasons of the year. This is true as regards the differences existing between morning and afternoon light, for during the darker months the light may average 30 per cent more intense during the morning than in the afternoon. The percentage of possible sunshine recorded during November, December, January and February averages 22 per cent for Cleveland, 44 per cent for Chicago, 54 per cent for New York, and 75 per cent for Los Angeles. From such variations in the amount of sunshine found in the various territories during the critical months, it is evident that there must be corresponding differences in the period of development of the crops, the growth of a crop being in general proportional to the amount of light it receives.



2147. Showing type of greenhouse constructed for obtaining the maximum amount of light in the short winter days. Dotted lines indicate position of sun at different periods of the day and year (at noon unless otherwise indicated). House 34 feet wide and 20 feet maximum height.

In the construction of greenhouses, therefore, it is important they should be designed to produce the maximum results during the critical light seasons. Theoretical diagrams are shown in Figs. 2144–8.

From a study of the light conditions in greenhouses, it has been found that large glass is superior to small glass because of the smaller amount of light-obstructing framework, but with present methods of construction there is a limit to the size of glass that can be safely employed. Moreover, high-angled roofs are much superior to low roofs from the light point of view, but their practical utility is somewhat limited. Experiments with different types of glass have shown that there may exist 18 per cent difference in the light-transmitting properties of No. 1 and No. 2 quality glass, and third quality glass is 33 per cent less effective than No. 1 quality. A slight annual deterioration in greenhouse glass must be expected owing to the formation of a film of oil, but this can be obviated to some extent. The nature of the reflecting surface of the greenhouse, degree of lapping, and other factors influence light. In the modern large house more uniform light conditions are obtained than in the early, smaller houses.



2148. Showing type of greenhouse constructed to obtain the maximum amount of light in short winter days. Modification of type shown in Fig. 2147. Obstructs more light than Fig. 2147, but could be built wider.

As regards the direction of the greenhouse, for most purposes the east and west house is preferable for obtaining light, but some crops are able to thrive better, especially in the spring months, in a house running north and south. Morning light being superior to afternoon light, an east and west house should be tilted somewhat toward the northeast, thus exposing the plants more directly to the morning light and making it possible to syringe with less liability to fungous infection of the plants.

G. E. STONE.

LIGHTFOÒTIA (Rev. John Lightfoot, 1735–1788, author of a flora of Scotland). *Campanulàceæ.* Undershrubs or herbs (annual, biennial, perennial), of Afr. and Madagascar, with very small blue, white or pink fls.: lvs. usually alternate (sometimes fascicled or opposite), entire or toothed, small, narrow and rigid: fls. variously arranged; calyx-tube adnate to ovary, the lobes persistent; corolla deeply 5-lobed or parted nearly to base, the stamens free: fr. a caps. dehiscing at the top. Species 40–50, Trop. Afr. to the Cape region. Two or three species are more or less mentioned in garden writings for greenhouse culture, but apparently none is in the trade. *L. tenélla,* Lodd. (*L. ciliàta,* Sond.), of the Cape, has erect woody branches and bluish racemose fls.: lvs. ovate-lanceolate, somewhat reflexed: 9 in. L.B.C. 11:1038. *L. subulàta,* L'Her. (*L. sessiliflòra,* Sond.). Lvs. very narrow, more or less spreading: st. ascending or erect, somewhat woody: fls. many, blue: 12–18 in. Cape. L. H. B.

LIGULÀRIA (name refers to the strap-shaped more or less bilabiate rays). Including *Farfùgium* and *Erythrochæte. Compósitæ.* Perennial herbs, some grown in the open for the striking flower-heads and leaves, but mostly indoors for the large and interesting foliage, or in summer bedding.

From Senecio, to which it is often referred, this genus differs largely in the character of the involucre, the scales or bracts of which are in one series at the insertion but of two forms so that the narrow outer ones overlap the edges of the broader inner ones; also in technical characters of the style. Lvs. mostly long-petioled, broad or even orbicular or reniform, sometimes palmate, those on the st. smaller and bearing large sheaths: heads large, reflexed or nodding, in corymbs or racemes; ligules or rays mostly long and narrow, usually yellow: achene glabrous, bearing soft pappus.—Species about 30, as now defined, from W. Eu. to Siberia, Himalayas and China-Japan. The plants impose no special difficulties in cult. They are prop. mostly by division.

Kaémpferi, Sieb. & Zucc. (*L. Farfùgium,* C. Koch. *Farfùgium Kaémpferi,* Benth. *Senècio Kaémpferi,* DC.). Rhizomatous perennial sending up many lvs. on slender flocculent-woolly petioles: lvs. large (often 6–10 in. across), orbicular to nearly reniform, cordate at base, angular-toothed, green: fl.-sts. 1–2 ft. tall, flocculent-woolly, branched, with only small, bract-like lvs.: heads large, with light yellow rays spreading 1½–2 in. across; pappus white and copious. Japan. Var. **aùreo-maculàtus,** Hort. (*Farfùgium gránde,*

2149. Leopard plant, or Farfugium—Ligularia Kaempferi var. aureo-maculatus. (×⅙)

Lindl. *F. maculàtum*, Hort.). Leopard Plant. Fig. 2149. Differs in having the lvs. blotched with yellow or white and sometimes with light rose. B.M. 5302. The variety *aureo-maculatus* is the only form in general cult. It was intro. to England in 1856 "from the garden of a mandarin in the north of China" by Fortune. Years ago this was a common plant in conservatories and window-gardens, but of late years it has been neglected. It is, however, a most worthy plant, not only for the house but for bedding in the open in shady places. The plant is hardy as far north as Washington when set permanently in the open. One form has yellow-spotted lvs. (the commoner) and another has white-spotted lvs. Another form (var. *argénteus*) has lvs. glaucous-green edged with creamy white. Easily prop. by division.

japónica, Less. (*Árnica japónica*, Thunb. *Senècio japónicus*, Schultz. *Erythrochæ̀te palmatífida*, Sieb. & Zucc.). Strong perennial herb, growing 5 ft. high (said to reach 15 ft. in S. Japan), and grown for its massive foliage effect: radical lvs. very large, 1 ft. or more across, deeply palmately cut into 7–11 narrow-lobed and notched divisions: fl.-sts. branched, bearing heads on rather long, naked sts.; rays orange, spreading, 3 in. from tip to tip. Japan. Summer. Gn. 22, p. 139. J.H. III. 54:276.—Intro. into this country about twenty-five to thirty years ago. It is a bold plant, hardy in N. Y., and well adapted to planting where strong foliage effects are desired, provided the place is moist.

sibírica, Cass. (*Cinerària sibírica*, Linn. *Senècio sibíricus*, Clarke. *Ligulària racemòsa*, DC. *Senècio Ligulària*, Hook. f.). Very variable, native from France to Japan: stout and erect, 3 to 4 ft.: lvs. to 1 ft. across, somewhat triangular to reniform or cordate-sagittate in outline, the basal sinus sometimes deep and sometimes shallow, obtuse or acute, the margin coarsely toothed, the petiole of the st.-lvs. winged and sheathing: heads many, each many-fld., somewhat secund in a terminal raceme; bracts of involucre 8–10; rays or ligules yellow, very long (½–¾in.); pappus reddish.—May be planted in the herbary. Said to be a showy marsh plant.

macrophýlla, DC. (*Senècio Lédebourii*, Schultz). Stout and erect, 3–6 ft.: lvs. very large, elliptic or oval-oblong, not sagittate or cordate at base, strongly toothed, long-petioled, sometimes 2 ft. long with petiole, those on the st. more or less clasping: heads yellow, in a long dense terminal spike or crowded panicle. Caucasus. —A striking and vigorous perennial. See *Senecio*, for another entry of this species.

L. H. B.

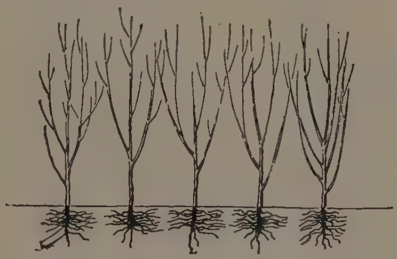
LIGÚSTICUM (Latin, referring to the ancient province of Liguria). *Umbellíferæ*. This includes a native hardy herb suitable for naturalizing with aquatics and bog-plants; offered by dealers in native plants. The ligusticums are glabrous perennials, with aromatic roots, large ternately compound lvs., mostly no involucre, involucels of narrow bractlets and white fls. in large, many-rayed umbels: fr. oblong or ovate, flattened laterally or not at all; oil-tubes 2–6.—Species about 20, in the northern hemisphere, of no horticultural prominence.

canadénse, Brit. (*Férula canadénsis* Linn. *L. actæifòlium*, Auth.). St. stout, 3–6 ft., branched above: lvs. 3–4-ternate; lfts. 2–5 in. long, coarsely serrate, broadly oblong: umbels 10–20-rayed: fruiting rays 1–2 in. long. July, Aug. Rich ground, S. Pa. to Ga. and Ala.

Wilhelm Miller.

LIGÙSTRUM (ancient Latin name). Including *Visiània*. *Oleàceæ*. Privet. Prim. Ornamental woody plants grown chiefly for their handsome foliage and the profusely produced white flowers; some species are excellent hedge plants.

Deciduous or evergreen shrubs, rarely trees: lvs. opposite, short-petioled, entire, without stipules: fls. perfect, in terminal panicles; calyx campanulate, obscurely 4-toothed; corolla funnel-shaped, with mostly rather short tube and with 4 spreading lobes; stamens 2: fr. a 1–4-seeded berry-like drupe.—About 50 species, chiefly in E. Asia and Himalayas, distributed south to Austral., one in Eu. and N. Afr.

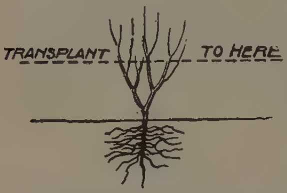


2150. Common method of making privet hedge. (Scale ½in. to 1 ft.)

The privets are much-branched shrubs or rarely small trees with usually medium-sized leaves and with large or small panicles of small, white, usually fragrant flowers followed by small black, or in some varieties greenish or yellowish white, berry-like fruits, often remaining on the branches through the whole winter. Some deciduous species, as *L. vulgare*, *L. Ibota*, *L. acuminatum*, and *L. amurense*, are hardy North, while others, like *L. ovalifolium*, *L. sinense* and *L. Quihoui*, can not be considered quite hardy north of Long Island. The evergreen species are only half-hardy or tender, but *L. japonicum* may be grown as far north as Philadelphia. They are all very valuable for shrubberies, with their clean, dark green foliage, which is rarely attacked by insects and keeps its green color mostly unchanged until late in fall, though *L. acuminatum* sheds the leaves rather early and *L. Ibota* and sometimes *L. ovalifolium* assume a pretty purplish hue; in mild winters some of the deciduous species hold part of their foliage until almost spring. *L. vulgare*, *L. ovalifolium* and others stand dust and smoke well and are valuable for planting in cities. *L. ovalifolium* is one of best shrubs for seaside planting, growing well in the very spray of the salt-water (known as California privet). Some are handsome in bloom, especially *L. sinense*, *L. Massalongianum*, *L. Ibota*, *L. japonicum*, *L. lucidum* and most of the other evergreen species; all are conspicuous in autumn and winter from the black berries, or in some varieties of *L. vulgare*, whitish, greenish or yellowish. *L. vulgare*, *L. ovalifolium* and *L. amurense* are well adapted for ornamental hedges; also *L. sinense* is used as a hedge plant, particularly in the South. The privets grow in almost any kind of soil, and even in rather dry situations and under the shade and drip of trees. Propagate by seeds sown in fall or stratified, sometimes not germinating until the second year; usually increased by cuttings of hardwood or by greenwood cuttings in summer under glass; varieties are sometimes grafted on *L. vulgare* or *L. ovalifolium*.

California privet for hedges. (Henry Hicks.)

First method.—Cuttings 8 to 14 inches of one-year wood are made in fall or winter, preferably the former, as they are occasionally damaged by the winter, even as far south as Alabama. These are tied in bundles and buried during winter. In the spring they are stuck in rows 2 to 6 inches by 2 to 3½ feet, and kept cultivated. They are sold at one year, when 1 to 2½ feet high, or at two years, when 2 to 4 feet high. If not sold at two years the plants are sometimes cut back to 3 inches to sprout again. They are dug by spade or tree-digger. These closely grown plants will make a hedge, as shown in Fig. 2150, especially if dug with spade and given short roots. If three-year plants, not cut back, are used, the base is open, as the old wood at the lower part of the plant has had its side branches weakened or killed by crowding and they do not readily branch out. Plants grown by this method are frequently planted in a double row.

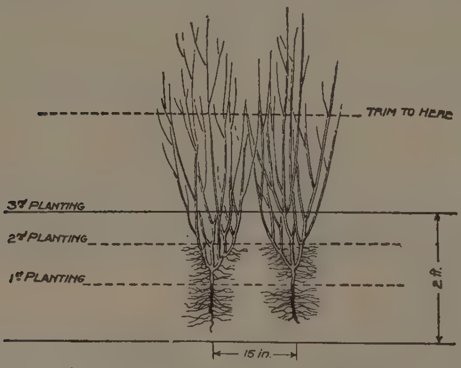


2151. California privet from short cuttings, transplanted deep. (Scale ½in. to 1 ft.).

Second method.—Cuttings of 5 to 6 inches of stout one-year wood, are made in November. The cuttings are made short so that the roots will not be cut off by the tree-digger. The leaves are stripped off, and the cuttings tied in small bundles, as large bundles mold. These are buried, tops up, over winter. In the spring, before growth starts, they are planted in rich mellow land 4 inches apart, with rows 8 inches apart. To plant, a back furrow is plowed in the center of the block, the top raked off, a line stretched and pegged down. The cuttings can then be inserted nearly full length. The trampling of the row settles the soil enough to expose the top buds. With a one-horse plow the bottom of the furrow is loosened where the planters have packed the soil, and new furrows are made around the strip planted. The cuttings are tilled during summer with a wheel-hoe or hand-plow. To make wide plants, the tips of the shoots are pinched when they are about 3 inches long. This is repeated at intervals of about three weeks during the summer. Nitrate of soda may be used to hasten growth. This method produces a plant as shown in Fig. 2151.

The plants may be dug in the fall and heeled-in to prevent possible winter-killing. They are then sorted into grades and planted in the spring 1½ to 2 feet apart in rows 3 to 4 feet apart against the landside of a deep furrow, and a little soil kicked over the roots. The filling is completed with a one-horse plow. Before filling, fine manure may be spread near the plants.

The plants should be straightened up and trampled firm. When finished, they should have the lower branches covered and the lower end of the cutting not below the level of the tree-digger. The pinching-back process may be continued, or the tips may be cut with a sickle during the early part of the season, especially on plants of the smaller grade. To get more roots on the branches the plants may be hilled-up. They are cultivated with a one-horse cultivator or a two-horse riding cultivator. At two years these will make plants 2½ to 3½ feet high and 1½ to 2 feet wide at the base.



2152. The privet hedge at final transplanting.

Dig with a tree-digger that operates on one or both sides. The plants may be set 12 to 15 inches apart, 4 to 6 inches deeper than before, and produce a hedge as shown in Fig. 2152. A smaller number of plants is required than when plants grown by the first method are used. As there are numerous vigorous buds near the ground, the growth is very dense at the base. After planting, the tops may be cut off to an even eight.

Various forms of hedge are used, as shown in Fig. 2153. No. *a* is used on Long Island; *b* is used at Newport. At Newport, by repeated clipping, the leaves become very small and the growth dense, resembling a wall. Nos. *d* and *e* frequently result from using narrow plants and allowing them to grow at the top.

Third method.—At Biltmore Nursery, North Carolina, the privet cuttings are run through a stalk-cutter and the pieces sown in a furrow.

2153. Conventional forms of California privet hedges.

A. *Corolla with the tube 2 or 3 times longer than the limb.*

B. *Lvs. linear-lanceolate or linear, evergreen.*

1. **Massalongiànum,** Vis. (*L. longifòlium, L. angustifòlium, L. myrtifòlium, L. rosmarinifòlium,* and *L. spicàtum*, Hort.). Erect shrub, to 3 ft., with warty and pilose branchlets: lvs. tapering at both ends, glabrous, 1½–3 in. long: panicles much branched, many-fld., with rather small pedicelled fls., 2½–3½ in. long. July, Aug. Himalayas. G.C. II. 16:149.—Graceful half-hardy shrub, one of the most floriferous.

BB. *Lvs. oblong to ovate or oval.*

C. *Young branchlets and infl. pubescent: lvs. deciduous.*

D. *Calyx glabrous or pubescent only at the base: habit upright or upright-spreading.*

2. **acuminàtum,** Koehne (*L. ciliàtum*, Rehd., not Blume. *L. mèdium*, Hort., not Franch. & Sav.). Shrub, to 6 ft., with erect and spreading branches: lvs. rhombic-ovate or ovate-lanceolate, acute at both ends, appressed pubescent near the margin and finely ciliate and pubescent on the midrib beneath, 1–3 in. long: panicles small, erect, 1–2 in. long; fls. almost sessile; calyx glabrous: fr. shining black, ovoid, ⅓in. long. June. Japan. S.T.S. 1:71. M.D. 1904, p. 73.—This species has been intro. under the erroneous denomination of *L. medium*, which is sometimes misspelled *L. meadia*. It is the first to lose its lvs. in autumn. Var. **macrocárpum,** Schneid. (*L. macrocárpum*, Koehne). More upright: lvs. larger: fr. larger, ½in. long. M.D. 1904, p. 75.

3. **amurénse,** Carr. (*L. Ibòta* var. *amurénse*, Hort.). Shrub, to 15 ft., with upright branches: lvs. oval or oblong, usually obtuse, somewhat glossy above, glabrous except the midrib beneath, 1–2½ in. long: pani-

cles erect, often rather many-fld., 1–2½ in. long; fls. short-pedicelled; calyx glabrous or slightly pubescent near the base: fr. slightly bloomy, ovoid, ⅓in. long. June, July. Japan, China. R.H. 1861, p. 352. S.T.S. 1:72. M.D. 1904, p. 72.—Similar in habit to *L. ovalifolium* and almost half-evergreen.

DD. *Calyx pubescent: habit wide-spreading.*

4. **Ibòta,** Sieb. (*L. obtusifòlium,* Sieb. & Zucc.). Fig. 2154. Shrub, to 10 ft., with spreading and curving branches: lvs. elliptic to oblong-obovate, acute or obtuse, usually only pubescent on the midrib beneath, 1–2 in. long: panicles nodding, small, 1–1½ in. long, numerous along the branches on short branchlets; fls. short-pedicelled; calyx pubescent: fr. with slight bloom, subglobose, ⅓in. long. June, July. Japan, China. G.F. 6:425. M.D.G. 1899:218. M.D. 1904, p. 71. S.I.F. 1:83. C.L.A. 3:180 (as var. *Regelianum*).—Graceful shrub, hardy N. Var. **Regeliànum,** Rehd. (*L. Regeliànum,* Koehne). Low, dense shrub with almost horizontally spreading branches and oblong or obovate, usually more pubescent lvs. M.D. 1904, p. 70. R.H. 1904, pp. 434, 435. F.E. 20:811 (as *L. amurense*).

CC. *Young parts glabrous: lvs. half-evergreen.*

5. **ovalifòlium,** Hassk. (*L. califórnicum,* Hort. *L. japónicum,* Hort., not Thunb. *L. mèdium,* Franch. & Sav.). CALIFORNIA PRIVET. Shrub of upright habit, to 15 ft., quite glabrous: lvs. cuneate at the base, elliptic-ovate or elliptic-oblong, acute, dark green and glossy above, yellowish green beneath, 1½–2½ in. long: panicles erect, many-fld., rather compact, to 3 in. long; fls. almost sessile. July. Japan. F.E. 33:1223. S.I.F. 1:84.—A very handsome shrub, but of somewhat stiff habit; well adapted and much used for hedges (see Mn. 6, p. 9). Var. **aùreo-marginàtum,** Hort. Lvs. edged yellow. Var. **variegàtum,** Hort. (var. *robústum variegàtum,* Hort.). Lvs. variegated with yellow. Var. **trícolor,** Hort. Lvs. variegated with yellowish and white, pinkish when young (Mn. 2, p. 42). Var. **multiflòrum,** Hort. Very free-flowering. G.C. III. 50:237.

AA. *Corolla with the tube as long as the limb or shorter.*

B. *Young growths glabrous: lvs. evergreen.*

6. **japónicum,** Thunb. (*L. glàbrum,* Hort. *L. Kelleriànum,* Vis. *L. Kéllermannii, L. Sièboldii, L. spicàtum,* and *L. syringæflòrum,* Hort.). Bushy shrub, to 10 ft.: lvs. roundish ovate to ovate-oblong, acute or obtusish, with reddish margin and midrib, veins beneath not distinctly marked, 2–3½ in. long: panicles broad, rather loose, to 4½ in. long; corolla-tube usually somewhat longer than calyx. July, Aug. Japan. R.B. 25:84. S.I.F. 1:82. G.W. 2, p. 567.—Very handsome evergreen shrub, but in colder climates often losing the lvs. in fall; often confounded with the following, and also with the preceding.

7. **lùcidum,** Ait. (*L. japónicum macrophýllum, L. magnoliæfòlium, L. sinénse latifòlium robústum* and *L. spicàtum,* Hort.). Large shrub or tree, to 20 ft., with somewhat spreading branches, similar to the former: lvs. larger, ovate to ovate-lanceolate, acute or acuminate, distinctly veined beneath, 3–5 in. long: panicles less loose, with almost sessile fls.; tube about as long as calyx. July, Aug. Japan, China. B.M. 2565; 2921 (as *L. nepalense glabrum*). G.C. II. 10:753.—Larger lvd. than the former, but more tender. It yields the white wax, an exudation of the branches, caused by an insect, Coccus Pe-lah; therefore cult. in China. Var. **Alivònii,** Arb. Kew. (*L. japónicum* var. *Alivònii,* André). Lvs. ovate-lanceolate, to 8 in. long, acuminate, sometimes with yellowish variegation when young. Var. **aùreo-marginàtum,** Hort. (*L. excélsum aùreum,* Hort.). Lvs. margined yellow. Var. **trícolor,** Arb. Kew. (*L. japónicum trícolor,* Hort.). Lvs. with yellowish variegation, pink when young.

8. **coriàceum,** Carr. (*L. lùcidum* var. *coriàceum,* Decne. *L. japónicum* var. *coriàceum,* Makino). Dwarf, dense shrub, with short, rigid branches, to 6 ft., very leafy: lvs. orbicular or orbicular-ovate, convex, dark green and shining above, 1½–2½ in. long: panicle compact, 2–4 in. long, with sessile fls. July. Cult. in Japan, not known wild. B.M. 7519. R.H. 1874, p. 418; 1888, p. 440. F. 1876, p. 65. G.C. III. 53:265.

BB. *Young branchlets and infl. pubescent or puberulous.*

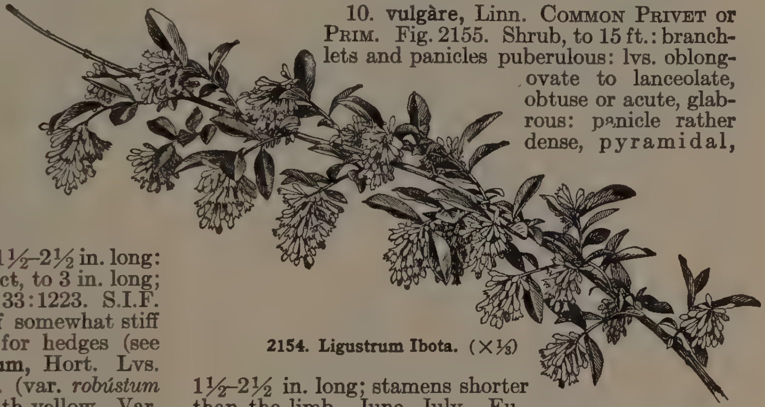
C. *Lvs. evergreen, 2–5 in. long.*

9. **nepalénse,** Wall. (*L. spicàtum,* Don). Evergreen shrub or tree, with pubescent branchlets: lvs. oblong or oblong-ovate, acuminate, pubescent beneath, 2–5 in. long: panicles rather large and broad, interspersed with petioled bracts. July, Aug. Himalayas.

CC. *Lvs. deciduous or half-evergreen, 1–2½ in. long.*

D. *Fls. pedicelled.*

10. **vulgàre,** Linn. COMMON PRIVET OR PRIM. Fig. 2155. Shrub, to 15 ft.: branchlets and panicles puberulous: lvs. oblong-ovate to lanceolate, obtuse or acute, glabrous: panicle rather dense, pyramidal, 1½–2½ in. long; stamens shorter than the limb. June, July. Eu., N. Afr., W. Asia. Naturalized in some places, chiefly in the E. B.B. (ed. 2) 2:729. F.E. 33:1273. H.W. 3:122.—Many garden forms. Var. **buxifòlium,** Nichols. Lvs. ovate or oblong-ovate, obtuse, half-evergreen. Var. **glaùcum,** Hoefker (var. *glaùcum álbo-marginàtum,* Spaeth). Lvs. bluish green, with narrow white margin. G.W. 2; p. 495. Var. **sempérvirens,** Loud. (*L. vulgàre* var. *itálicum,* Kirchn. *L. itálicum,* Mill. *L. sempérvirens,* Pieri). Lvs. linear-lanceolate, almost evergreen. Var. **péndulum,** Hort., with pendulous branches. Var. **pyramidàle,** Spaeth, with strictly upright branches. There are also varieties with frs. of different colors, as var. **chlorocárpum,** Loud., with greenish, var. **leucococárpum,** Loud., with whitish, and var. **xanthocárpum,** Loud., with yellowish frs. Variegated forms are: var. **aùreum,** Hort., with yellow foliage, and var. **variegàtum,** Hort., with the lvs. blotched yellow. Var. **lutéscens,** Hort., has deep cream-yellow fls.

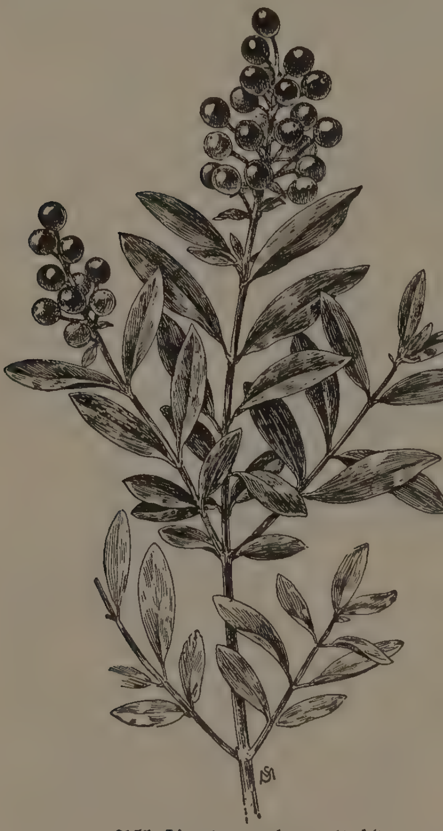


2154. Ligustrum Ibota. (×⅓)

11. **sinénse,** Lour. (*L. Fórtunei,* Hort. *L. villòsum,* May). Shrub, to 8 ft., with slender spreading branches. branchlets pubescent: lvs. elliptic to ovate-lanceolate, usually acute, pubescent along the midrib beneath, at least when young, 1–3 in. long: panicles pubescent, loose, to 4 in. long, with distinctly pedicelled fls.; stamens longer than the limb. China, Korea. G.C. 1858: 621. Var. **Staùntonii,** Rehd. (*L. Staùntoni,* DC.). Less high and more spreading: lvs. oval to ovate, usually obtusish, pubescent on midrib beneath: panicle broader and more loose. G.C. II. 10:365. G.F. 3:213. Var. **nítidum,** Rehd. Branchlets puberulous or minutely pilose: lvs. ovate-oblong to ovate-lanceolate, acute or acuminate, lustrous above. Cent. and W. China.—In some southern nurseries *L. sinense* has been offered under the name of *L. amurense*.

DD. *Fls. sessile.*

12. **Quihòui,** Carr. (*L. brachystáchyum,* Decne.). Shrub, to 6 ft., with spreading branches: branchlets and panicles finely pubescent: lvs. elliptic-oblong or narrow-oblong, obtuse, glabrous, somewhat coriaceous, 1–2 in. long: fls. sessile, in small clusters, forming at ends of the branches long, panicled spikes. Sept.–Oct. China. G.C. II. 18, p. 277. Gn. 66, p. 292.



2155. Ligustrum vulgare. (×½)

L. acutíssimum, Koehne. Allied to L. Ibota. Lvs. lanceolate, acuminate, ½–2½ in. long: panicle about 1 in. long; calyx glabrous; anthers shorter than limb. Cent. China.—*L. ciliàtum,* Sieb. Allied to L. acuminatum. Lvs. rhombic-ovate, acute, ciliate: panicle dense, small, about ½in. long, 4–8-fld. Japan.—*L. compáctum,* Hook. f. & Thoms. (L. lancifolium, Carr. L. longifolium and L. lineare, Hort., and L. Simoni, Carr.). Evergreen shrub, quite glabrous: lvs. lanceolate, to 6 in.: panicle large, compact; tube short. Himalayas. R.H. 1902, p. 500.—*L. Delavayànum,* Hariot (L. Prattii Koehne). Low evergreen shrub with spreading or nearly prostrate, pubescent branches: lvs. ovate to ovate-oblong, glabrous, ½–1½ in. long: panicles narrow, leafy at the base, 1–1½ in. long; corolla-tube longer than the limb. W. China. R.H. 1901, p. 496 (habit).—*L. Hénryi,* Hemsl. Evergreen shrub, to 12 ft.: branchlets pubescent: lvs. orbicular-ovate to ovate-lanceolate, obtusely acuminate, dark green, glabrous, ¾–2 in. long: panicles terminal, short-stalked, 1½–4 in. long; corolla-tube longer than limb; calyx glabrous. W. China.—*L. insulàre,* Decne. (L. Stauntonii, Hort., not DC.). Shrub, to 6 ft., allied to L. vulgare: lvs. elliptic-ovate to linear-lanceolate, yellowish green, often pendulous, 2–3 in.: panicles rather large. Origin uncertain.—*L. lancifòlium,* Carr., *L. longifòlium,* and *L. lineàre,* Hort.=L. compactum.—*L. pekinénse,* Hort. =Syringa pekinensis.—*L. Práttii,* Koehne=L. Delavayanum.—*L. Sìmoni,* Carr.=L. compactum.—*L. Staùntonii,* Hort.=L. insulare.—*L. strongylophýllum,* Hemsl. Evergreen shrub or small tree, almost glabrous: lvs. orbicular or obovate, ½–1 in.: panicle rather loose. Cent. China. B.M. 8069.—*L. Wálkeri,* Decne. Allied to L. nepalense: lvs. ovate to lanceolate, glabrous, to 3 in.: panicle large, to 6 in. Ceylon, Neilgherries. G.C. III. 24:282. G.M. 41:683.—*L. yunnanénse,* L. Henry. Shrub, to 12 ft.: branches glabrous: lvs. subcoriaceous, deciduous, oblong-lanceolate, glabrous, 2–5 in. long: panicle loose, 5–7 in. long; corolla-tube short. Yunnan. R.H. 1902, pp. 498–500.

ALFRED REHDER.

LILAC: *Syringa.*

LÍLIUM (Latin, from the Greek name, said to be derived from the Celtic word *li,* meaning whiteness, referring to *L. candidum*). *Liliàceæ.* LILY. Noble plants for outdoor bloom, and a few of them grown under glass. They comprise one of the distinctive flower forms, and the name lily is applied to many other plants.

Herbaceous perennials with scaly bulbs: sts. unbranched, smooth or pubescent, usually bright green, sometimes tinged purple or brown and generally clothed with lvs. their entire length: lvs. (except in only 2 species, *L. cordifolium* and *L. giganteum*) always linear or lanceolate, either scattered or verticillate, usually bright green and quite sessile, but in a few species with short petioles: fls. terminal, solitary, racemose or umbellate, perfect, with 6 perianth-segms., 3 like sepals or calyx-lvs. and 3 like petals or corolla-lvs., the parts erect or variously spreading or reflexed (Figs. 2156, 2157), usually with a honey-bearing gland at the base of each; each fl. has 6 prominent stamens and 1 long pistil; each stamen consists of a filament or stalk and an anther balanced on its end and attached by its back, while the ovary bears a style and a 3-lobed stigma: the fr. or seed-vessel is an oblong caps. borne above the base of the perianth-segms.; it is 6-ribbed, divided into 3 cells, each cell closely packed with flattened, brown, soft-coated seeds. The genus is divided into 7 groups or subgenera, distinguished from each other chiefly by the shape and arrangement of the fls. These groups are:

I. Eulirion (true lilies, trumpet- or funnel-flowered lilies).
II. Archelirion (open-flowered lilies).
III. Martagon (Turk's-cap or turban-shaped lilies).
IV. Pseudo-Martagon (bell-flowered lilies).
V. Isolirion (erect- or upright-flowered lilies).
VI. Cardiocrinum (heart-shaped-leaved lilies).
VII. Notholirion (fritillaria-like lilies).

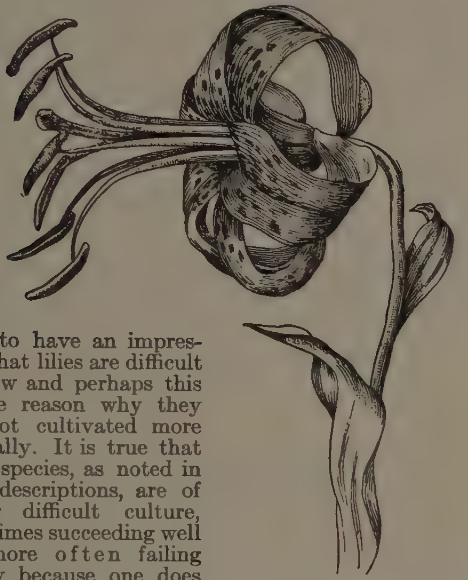
From 300–400 species have been described, but there are probably considerably less than 100 entitled to rank as such. They are all natives of the northern hemisphere, extending around the world. Their northern limit is southern Canada and Siberia; their southern, Florida and the Neilgherry Mts. of India. Many of them are in California and China-Japan.

The genus Lilium is very closely allied to Fritillaria; the latter genus differs in the corolla being more uniformly campanulate, with nectar-bearing cavities at the base of the inner segms. or of all of them, and the anthers attached by the base. *Lilium roseum* is by some referred to Fritillaria, but it is probably better kept in Lilium. *L. oxypetalum* is a similar case.

For further botanical information, the reader is referred to "The Botanical Gazette," 27:235 (1899), where a botanical review of the genus will be found. The most notable monograph on lilies is entitled "A Monograph of the Genus Lilium," by H. J. Elwes, published in 1880 and containing superb colored plates. It is referred to below by the abbreviation El. It covers the ground fully up to the date of publication. Unfortunately there is no book yet published which combines the botanical and horticultural points of view, but much valuable cultural information may be obtained by reading the following four books: Wallace's "Notes on Lilies," 2nd edition; "Lilies for English Gardens," by Miss Jekyll; "The Book of the Lily," by Wm. Goldring, and "Lilies," by Adams and one by A. Grove. Many portraits have been made of species of Lilium, some of the most important and accessible of which are cited in the following account. The author cannot vouch for the authenticity of these portraits, however.

The general cultivation of lilies.

The various lilies are unequaled by any other plant in their unique combination of beauty, gracefulness and stately magnificence; yet they are entirely unknown in many gardens, while in others only a few of the commoner species, like *L. candidum*, *L. speciosum* or *L. tigrinum* are seen. Their culture has been entirely too much neglected in this country, but we are confident that, as their merits become better known, they will be much more largely grown. Many persons seem to have an impression that lilies are difficult to grow and perhaps this is one reason why they are not cultivated more generally. It is true that a few species, as noted in their descriptions, are of rather difficult culture, sometimes succeeding well but more often failing simply because one does not fully understand their needs. It must be remembered that, in their native habitats, the different lilies are found under widely varying conditions of soil, climate and environment, and some kinds are so delicate and capricious that they will not succeed well under cultivation unless the peculiar conditions under which they are found in a wild state can be closely imitated. But, on the contrary, most lilies are robust, long-lived and of easy culture under a variety of soil and climatic conditions. The beginner in lily-culture should always select these easily grown kinds, choosing them according to his own individual taste. There are enough of these to satisfy any ordinary cultivator, unless he becomes an enthusiast or specialist, desirous of securing as large a collection as possible of different species and varieties. In that case, and if space, time and means will permit, he may attempt the culture of the more capricious sorts. The following is a selection of twelve of the best easily grown lilies for general cultivation: *L. candidum*, *L. regale*, *L. auratum* var. *platyphyllum*, *L. speciosum* var. *magnificum*, *L. tigrinum* var. *splendens*, *L. monadelphum*, *L. superbum*, *L. testaceum*, *L. Martagon* var. *glabrum*, *L. tenuifolium*, *L. croceum*, *L. dauricum* var. *incomparabile*.



2156. A lily form.—One of the turban or Turk's-cap group, Lilium superbum.

By using care and judgment, suitable lilies may be chosen for almost any location or purpose. Nearly all species are desirable for planting in combination with other hardy perennial plants or scattered among dwarf-growing shrubs in such a manner that the flowers will rise above their foliage, thus imitating nature, for in a wild state the lower part of the stem of many species is thickly surrounded with grass or dwarf undergrowth, while the upper part and flowers rise free. Many lilies also produce a charming effect when planted in front of large shrubs, such as magnolias and rhododendrons, the flowers showing up well against the background of green. For large beds or massing, only such kinds as produce a showy display of flowers should be chosen. *L. candidum*, *L. dauricum*, *L. elegans*, *L. speciosum*, *L. tigrinum* and their varieties are especially desirable for this purpose. Sometimes different species or varieties are planted together in the same bed, but, unless space is limited, it is usually better to keep them separate. Any of the strong-growing permanent lilies, *L. superbum*, *L. tigrinum*, and many others, are excellent for naturalizing in wild or uncultivated ground. Some of the smaller-growing kinds, like *L. concolor*, *L. elegans*, *L. tenuifolium*, are desirable for planting in rock-gardens with other plants. In the northern states the capricious sorts, like *L. japonicum* and *L. Leichtlinii*, often succeed better when grown in coldframes or pots than in the open ground, and if their culture is attempted this method is recommended.

The flowers of all lilies, with the exception of a few ill-smelling species, are excellent for cutting. Only the upper part of the stem should be cut off, however, leaving the foliage on the lower part, so the bulb may complete its growth. If the stem is cut off right down to the ground when in active growth, the bulb will be injured or perhaps destroyed.

Soils and location.

Most lilies will succeed in any light, sandy or loamy soil. Decayed peat or leaf-mold may be added with advantage, as the American species are especially partial to a peaty soil. Some species, like *L. candidum*, *L. croceum*, *L. elegans*, *L. Hansonii*, *L. monadelphum*, *L. tigrinum* and most of the European Turk's-cap lilies will also do well in a heavier soil, even clay if it is well drained. Good drainage is an essential point, for no lilies, with the possible exception of *L. canadense* and *L. superbum*, will live in a wet or swampy soil, where stagnant water stands around the bulbs. Whenever possible, a slightly sloping location with a porous gravelly subsoil should be chosen. Several species, like *L. candidum*, *L. chalcedonicum*, *L. carniolicum*, *L. Hansonii*, *L. monadelphum*, *L. Martagon*, *L. pomponium*, *L. testaceum* and a few others will thrive in a calcareous or limestone soil, but lime is poison to most lilies and with these exceptions they should never be planted in soils containing it. Of whatever nature the soil, it should be fairly rich and if not naturally so a liberal quantity of thorougly decayed cow- or sheep-manure should be mixed in before planting the bulbs. In after years, additional nourishment may be provided by top-dressings of decayed manure. Fresh manure of any kind should never be used, as it attracts worms and causes the bulbs to decay.

Although, as noted above, good drainage is necessary, yet lilies like plenty of moisture when in active growth. Frequent shallow cultivation or mulching will help to conserve the moisture already in the soil, but in periods of drought artificial watering may be necessary.

Some lilies, as *L. candidum*, *L. croceum*, *L. elegans*, *L. Martagon*, *L. monadelphum* and *L. tigrinum*, will often succeed very well in full sunshine and exposure. Others, however, like *L. auratum*, *L. Hansonii*, *L. Henryi*, *L. japonicum*, *L. Parryi*, *L. washingtonianum*, often fail or the flowers bleach or fade quickly in such situations. As a rule, however, it may be said that all lilies will thrive better in partial shade, and the flowers will last longer. The ideal location is under trees or large shrubs, but far enough away so that their roots will not rob the lilies of moisture and

2157. A lily form.—One of the Archelirion kinds. Form of L. speciosum.

nourishment. In such places, they will receive a free circulation of light and air, but the the full force of the hot midday sun cannot reach them.

Protection from cold and wind.

In cold climates, the bulbs of all lilies should be protected from freezing during winter by a heavy covering of leaves, hay or straw. Some species, as *L. bulbiferum*, *L. candidum*, *L. elegans*, *L. tigrinum*, are apparently not greatly injured if the bulbs freeze, but frost is fatal to many, especially the Californian and Indian species, and even the hardiest kinds will do better if the bulbs are protected from it. Frost sometimes also injures the tender young growth of *L. auratum*, *L. chalcedonicum*, *L. Hansonii*, *L. longiflorum*, *L. speciosum*, *L. testaceum* and others which appear above ground very early in spring. This can be prevented by covering the plants with old sheets, or something similar, on cold nights when frost is expected.

To prevent the stems of lilies from being broken by high winds, each plant or clump should be supported with a stick or stake, preferably of bamboo, tying them together with soft yarn or twine. It is better, however, wherever possible, to plant lilies in such a way that they will not require staking, as this deprives them of their natural gracefulness of swaying with the breeze.

The planting.

The best time to plant lily bulbs is soon after the flowers fade or seeds ripen. They cannot always be obtained at that time, however, imported ones often not being received until late in autumn or winter. In the northern states, the places intended for these late-received bulbs should be prepared previously and covered with 5 or 6 inches of leaves or litter, to prevent the ground from freezing. This should be removed and the bulbs planted as soon as received, afterward replacing it as a winter mulch. Or, if preferred, the bulbs may be packed in boxes of sand, leaf-mold or sphagnum moss and stored in a cool dark frost-proof cellar, closet, or shed until spring, when they should be planted. The material they are packed in must be kept constantly moist, neither too wet nor too dry. In this connection it might be well to add a few words of advice in regard to the purchase of lily bulbs. Whenever possible, freshly dug home-grown bulbs should be secured or at least those which have been shipped only short distances, which have not been deprived of their roots, and whose scales have not become dried or shriveled. Such bulbs, although they may cost more than imported ones, which have often been kept out of the ground for several months, are well worth the difference.

No definite rules can be given in regard to the proper depth and distance apart to plant the bulbs, but usually they should be set so that their top or apex will be three times as deep as their greatest diameter. The smaller-growing species, as *L. concolor*, *L. elegans*, and *L. tenuifolium*, may be planted about 6 inches apart, while from 12 to 18 inches is not too much space for the largest species, like *L. auratum*, *L. tigrinum*, and so on. When planting the bulbs, it is a good plan to surround each one with sand or fine gravel, which helps to drain away surplus moisture and also tends to repel worms. Some growers also place a handful of fresh sphagnum moss under each bulb, thinking it induces a better root-growth.

It is the nature of many lilies to throw out annual fibrous roots from the underground stem above the bulb (called stem-roots), in addition to the large permanent ones at its base (called basal or bulb-roots). The following species and their varieties belong to this class: *L. auratum*, *L. Batemanniæ*, *L. Brownii*, *L. bulbiferum*, *L. concolor*, *L. croceum*, *L. dauricum*, *L. elegans*, *L. Hansonii*, *L. Henryi*, *L. japonicum*, *L. Leichtlinii*, *L. longiflorum*, *L. Maximowiczii*, *L. medeoloides*, *L. odorum*, *L. regale*, *L. rubellum*, *L. Sargentiæ*, *L. speciosum*, *L. sulphureum*, *L. sutchuenense*, *L. tigrinum* and *L. Wallacei*.

The following species and their varieties produce but few, if any, stem-roots: *L. Bolanderi*, *L. callosum*, *L. canadense*, *L. candidum*, *L. carniolicum*, *L. caroliniаnum*, *L. chalcedonicum*, *L. columbianum*, *L. giganteum*, *L. Grayi*, *L. Humboldtii*, *L. Kelloggii*, *L. maritimum*, *L. Martagon*, *L. monadelphum*, *L. pardalinum*, *L. Parryi*, *L. parviflorum*, *L. parvum*, *L. philadelphicum*, *L. pomponium*, *L. pyrenaicum*, *L. Roezlii*, *L. superbum*, *L. tenuifolium*, *L. testaceum* and *L. washingtonianum*.

The bulbs of these non-stem-rooting species, when not received or planted until late autumn or spring, often remain dormant until the second summer, because the basal roots, on which the flower-stem must depend entirely for its support, have been cut off or dried up by exposure to the air, and consequently the bulbs are so weakened that it takes them a year or more to recover and form new roots. Sometimes, however, a small weak stem develops the first summer, which soon perishes without flowering. On the contrary, the stem-rooting species usually bloom well the first summer after planting, because, even if the bulbs do not produce roots they are formed at the base of the stem, which is nourished and supported by them.

Propagation.

Lilies are propagated by division of the offsets, by bulbils, by scales or by seeds. The best and easiest method with most species is by division of the offsets, which form at the base of the parent bulb, on the underground stem above the bulb, or on the end of a rhizome. The best time to do this dividing and replanting is from two to four weeks after the flowers fade or immediately after seeds ripen, as that is the only time the bulbs are really dormant and many species greatly dislike to be disturbed when the roots are in active growth. The clumps should be carefully dug up and the large flowering bulbs planted immediately where they are to remain permanently, while the smaller ones may be planted in beds by themselves, removing them to their permanent location when they become large enough to bloom, which will usually be in two or three years.

Sometimes, when separating and replanting the bulbs, fresh healthy scales become detached. If these are planted in rows 2 inches apart and 1 or 2 inches deep, in light sandy soil, either in boxes, coldframes or the open ground, one or more tiny bulbs will usually form at the base of each scale, where it was broken off. These will become large enough to bloom in two or three years.

L. bulbiferum, *L. Sargentiæ*, *L. suphureum* and *L. tigrinum* and its varieties usually produce small dark green or purple bulbils or bulblets in the upper leaf-axils. If these are removed before they drop to the ground and planted, like the detached scales, they will bloom in two or three years.

Raising lilies from seeds is very interesting, but it requires time, care and patience. Under favorable conditions, most lilies will produce seeds, but a few species often remain sterile, unless the flowers are hand-fertilized. Among these may be mentioned *L. Brownii*, *L. candidum*, *L. Hansonii*, *L. longiflorum*, *L. speciosum*, *L. sulphureum*, *L. testaceum*, *L. tigrinum*, *L. Wallichianum* and some varieties of *L. elegans*. Freshly-gathered seeds, sown soon after they ripen, will germinate more quickly than those which have been kept until they become hard and dry, but in all cases the period of time required for germination varies greatly with the species. For example, fresh seeds of *L. tenuifolium* will often germinate in a month, or even less, while those of *L. auratum* and many others will seldom germinate until the following spring and often not until a year later. Similarly, the time required for the seedlings to become large enough to bloom varies greatly. *L. philadelphicum*, *L. tenuifolium* and a few others will often bloom the second summer after the seeds germinate, while *L. giganteum* seldom blooms before five or six years have passed. Most species, however, require three or four years. The seeds should be sown thinly in boxes of light sandy soil, in rows about 2 inches apart and covered about ½ inch deep with finely sifted sphagnum moss. The boxes should be kept in the house or greenhouse until the seedlings appear, when they may be set outdoors, in a shady place, during the summer. When the young plants are 2 or 3 inches high, they should be transplanted into coldframes or prepared beds in the open ground, later removing them to their permanent location.

Insects and diseases.

Lilies are seldom troubled by insect foes of any kind. Worms will sometimes eat the bulbs, but if they are surrounded with sand, as previously suggested, and fresh manure is never used, they will not be likely to be attacked. Mice will also eat the bulbs and the only way to get rid of them is by poisoning or trapping. Aphis or green-flies occasionally attack the plants, especially when under glass, but they may be readily destroyed by spraying the plants with kerosene emulsion.

There are several fungous diseases that are very destructive to lilies. Probably the worst and most common one is a species of Botrytis. It attacks all kinds of lilies, without any exception, either wild or cultivated, and may appear at any stage of their growth. It is first noticed as buff or rust-colored spots or blotches on the leaves or buds, which soon become covered with a grayish mold. When the disease first appears, all affected parts should be cut off and burned, while the attacked plants, as well as healthy ones growing near them, should be sprayed with some good fungicide, like bordeaux mixture. Then, if the disease persists in spreading, the only thing to do is to dig up the plants, bulbs, roots and all, and burn them.

Another fungous disease, known as *Rhizopus necans*, is very destructive to imported Japanese bulbs, especially those of *L. auratum*. It attacks the base of the scales, causing them to decay, and the bulbs, if left exposed to the air for a few days, become soft and rotten and covered with a long white silky fungous growth. As soon as the bulbs are received, they should be carefully examined and those that show the least signs of the disease burned at once, as they seldom recover. Those which appear perfectly sound are often covered with the spores of the fungus and to destroy them the bulbs should be soaked for several hours in a solution of one part carbolic acid to forty parts water. Another method, practised by some growers to prevent the disease from being introduced into their gardens, is to plant the apparently sound bulbs singly in pots or tin cans, and later, those which are healthy and well-rooted should be transplanted to the open ground, while diseased ones should be burned and the soil in the pots sterilized.

The American florists' lily trade. (David Lumsden.)

The lily has become one of the popular plants of the American trade. Its popularity is due not alone to the fact that *Lilium longiflorum* is the acknowledged Easter lily of commerce, but it is a plant particularly well adapted for church, wedding and other decorations at any season of the year. Lilies are also exceptionally useful as cut-flowers for design work and for Memorial Day trade.

Many million bulbs of *L. longiflorum* and its varieties are imported from Japan, Formosa and Bermuda each year. It is an exceedingly important commercial crop, and several of the larger eastern and western growers force as many as 200,000 bulbs in a single season.

Lilium longiflorum var. *eximium*, which is grown under the trade name of *L. Harrisii*, was for years the principal variety grown for early blooms and for Easter sale. Unfortunately, the variety is attacked by a bacterial disease, and healthy stock is almost impossible to obtain. The lily disease is prevalent in all sections and countries from which the bulbs are imported, and growers find, under forcing conditions, that from 3 per cent to 33⅓ per cent of the bulbs are affected. *L. longiflorum* var. *eximium* is especially susceptible to the disease, but all varieties are now attacked to a greater or less degree. Within the last few years, however, more careful propagation and better cultural conditions have eliminated the disease to a considerable extent, and as a result, there has been an improvement in the crop.

During the earlier period of forcing Easter lilies, they were placed on the market only in the late winter or early spring months. Within recent years, improved methods of cold storage have made possible the production of blooms of the so-called Easter lilies at any season of the year. However, the larger number of blooms are placed on the market in Easter week, for in the minds of the flower-loving public no other flower is so suggestive of the Easter spirit.

The species of lilies forced under glass may be divided into three groups:

GROUP I. *Lilium longiflorum*, Easter lily.

- (*a*) *Lilium longiflorum*.
- (*b*) *Lilium longiflorum*, Formosa type.
- (*c*) *Lilium longiflorum* var. *eximium* (*L. Harrisii*).
- (*d*) *Lilium longiflorum* var. *giganteum*.
- (*e*) *Lilium longiflorum* var. *multiflorum*.

Lilium longiflorum var. *giganteum* is now the most popular for Easter trade; it is also the lily used almost exclusively for cold storage. *L. longiflorum*, Formosa type, *L. longiflorum* var. *multiflorum*, and *L. longiflorum* var. *eximium*, are used more especially for earlier flowering.

GROUP II. *Lilium speciosum* (*L. lancifolium*).

- (*a*) *Lilium speciosum* var. *album*.
- (*b*) *Lilium speciosum* var. *rubrum*.
- (*c*) *Lilium speciosum* var. *roseum*.
- (*d*) *Lilium speciosum* var. *Melpomene*.

Lilium speciosum ranks next to *L. longiflorum* as the most valuable for forcing. The varieties *album*, *roseum*, and *rubrum* are the most in demand. They are now forced in winter and spring by using bulbs that have been retarded in the cold storage. The natural blooming period of this species is July and August, and the flowers are then useful for floral designs and cut-flowers.

GROUP III. *Lilium candidum* (Madonna lily).

There are two forms of *L. candidum;* one with thin, star-like petals, not much recurved; the other having the broad, stoutly ribbed petals strongly recurved. This latter type is the one most commonly used for forcing. Bulbs of *L. candidum* are now imported from northern France. Recently, the lily disease has been so prevalent in the Marseilles district that the stock from that section has been less used for forcing purposes.

Forcing of lilies under glass.

When the bulbs are received, they should be potted into suitable-sized well-drained flower-pots, using a compost of three parts of good fibrous loam to one part of well-decayed horse- or cow-manure. There is a difference of opinion as to potting methods. Some growers prefer to place the bulbs first in 4-inch flower-pots, and when a strong root-system has developed, they are shifted into 6- or 7-inch flowering pots. Other growers place the bulbs directly in 6-inch pots, filling them about one-half full of compost, and at a later date when active growth has begun, a rich top-dressing of equal parts loam and cow-manure is added.

When the lilies are first potted, they are placed in a coldframe, watered thoroughly and covered with sphagnum moss, straw, or cinders. Wooden shutters are placed over the frames to keep the bulbs dark and to protect them from rain and heavy freezing. Under such conditions the bulbs will root readily. Before hard frosts, they are removed to a greenhouse and given a temperature of 45° to 50° F. at night for a week or ten days. When top-growth commences, a steady night temperature of 60° F. is maintained, raising the temperature to 70° during the day. Lilies should be given abundant ventilation and the plants should be freely syringed on bright mornings, but the foliage should be dry during the night.

It will require approximately thirteen weeks from the time that the plants are brought into the house to get them into flower, provided a temperature of 60° F. is maintained. It should be remembered, however, that weather conditions are dominant factors in lily-forcing; therefore, allowance must be made for a longer period for forcing if the weather is exceptionally dark or cloudy. Sometimes a slightly increased temperature shortens the period of forcing, and such an increase is not detrimental to the value of the flowers. If the buds are forced into flower at too high temperature, however, the keeping qualities of the flowers may be considerably injured. In order to have lilies in their prime for Easter, the buds should show about six weeks previous to that date. They may then be gradually developed, and if they advance too rapidly, they may be placed in a cooler temperature. No group of lilies will develop evenly, and it often requires excellent judgment so to shift the plants into different temperatures that the blooms will open at the proper date. If lilies are too advanced, retarding should not begin until the buds have lost their green color, for when once retarded, it is difficult to start them into growth again. A temperature of 45° to 50° F. at night, with a light shading on the glass, is recommended for developing the flower-buds.

For best success in forcing lilies, the water used for both watering and syringing should be warmed to about 70° F. Soil moisture extremes, caused by over-watering or by neglect, should be avoided.

When the lilies begin to show the buds, a weekly application of liquid manure may be given, using one bushel of cow-manure to fifty gallons of water. If the growth is very slow, three pounds of sodium nitrate may be added to the liquid manure, or it may be used separately in liquid form, using one ounce to one gallon of water.

If the plants are tall, they should be tied erect to neat stakes. Under forced conditions, the lily seems particularly susceptible to attacks of green aphis; therefore, fumigations and spraying with nicotine should be practised regularly throughout the period of growth. If young plants are kept free from aphis, they will be less likely to gain a foothold on the buds. They are particularly injurious to developing buds, for their attacks result in a malformation of the tissue.

Cold-storage lilies.

These are used for planting only from March 1 to September 1, the regular stock being depended on for the remainder of the year. The culture of cold-storage lilies differs from that pursued in the growing of lilies for Easter, as they may be placed in the forcing-house with a temperature of 60° F. immediately after potting. During the warm months, they will bloom in ten weeks from the time started. Those started earlier will require from ten to thirteen weeks.

Lilium speciosum and its varieties are easily grown. The method of culture does not vary much from that of *L. longiflorum.* They are grown either singly in 6-inch pots or planted in boxes. These boxes are 6 inches deep, and the bulbs are placed about 6 inches apart. The box method of culture is recommended because the roots of the lilies are not so liable to dry out as when pots are used.

Lilium candidum differs from *L. longiflorum* and *L. speciosum* in its temperature requirements. Too high temperature is disastrous to it, and a temperature of 50° or 55° F. suits it best. This species is seldom forced except for Easter and Memorial Day trade.

Notes on lily culture.

Allow thirteen weeks from the time the lilies are brought into the greenhouses, to get them into flower. A temperature of 60° F. at night, and 70° F. during the day, will be required.

It will take six weeks from the time the buds show, to the flowering period.

The best cold-storage temperature for lily bulbs is 34° F.

One of the most satisfactory lilies for Christmas is *Lilium longiflorum* var. *giganteum.* The bulbs should be potted September 15. *L. longiflorum* var. *giganteum* to be in flower for Easter should be potted in November.

By weekly plantings and proper culture, it is possible to have lilies in bloom throughout the year.

Early shipments of lilies arrive in time to follow the last of the cold-storage bulbs.

KEY TO THE SUBGENERA.

Perianth trumpet- or funnel-shaped, horizontal or nearly so, with oblanceolate segms., broadest near the end, smooth inside, falcate only at the tip or apex; stamens slightly curved, parallel with the style. I. EULIRION. Species 1–15.

Perianth broadly funnel- or bell-shaped, but without any tube, horizontal or becoming pendulous; segms. ovate-lanceolate, broadest near the base, papillose inside and becoming deeply falcate; stamens diverging widely from the curved style: lvs. scattered, 5–7-nerved. II. ARCHELIRION. Species 16–19.

Perianth broadly bell-shaped, pendulous or nearly so; segms. usually lanceolate, broadest near the middle, sometimes slightly ovate-lanceolate, becoming deeply recurved or reflexed, and, unless noted, smooth inside; stamens diverging on all sides from the curved or almost straight style. III. MARTAGON. Species 20–41.

Perianth bell- or thimble-shaped, with oblanceolate segms., smooth inside, slightly or not at all reflexed; stamens diverging from the almost straight style: lvs. verticillate, usually 3–5-nerved. IV. PSEUDO-MARTAGON. Species 42–46.

Perianth erect, broadly funnel-shaped; segms. lanceolate or nearly so, usually spathulate or clawed at the base and, unless noted, papillose or lamellate inside; stamens diverging on all sides from the straight or slightly curved style: lvs. usually 3–5-nerved. V. ISOLIRION. Species 47–56.

Perianth trumpet- or funnel-shaped, with oblanceolate segms., smooth inside, falcate only at the apex; stamens slightly curved, parallel with the style: lvs. cordate or heart-shaped with long petioles, many nerved. VI. CARDIOCRINUM. Species 57–58.

Perianth campanulate-funnelform, with distinct and separate segms., horizontal or declined; stamens slightly declined, equaling or somewhat exceeding the curved style; stigma prominently 3-lobed. VII. NOTHOLIRION. Species 59.

SUBGENUS I. EULIRION.

A. *Tube scarcely widened from base to middle.*
  B. *Lvs. scattered, 1–3-nerved*.......... 1. **philippinense**
  BB. *Lvs. scattered, 3–5-nerved.*
    C. *Fls. pure white*.................. 2. **longiflorum**
    CC. *Fls. white or yellow, tinged brown or purple.*
      D. *St. entirely green.*
        E. *Plant erect from the bulb*.... 3. **Wallichianum**
        EE. *Plant with parts creeping along under ground*....... 4. **neilgherrens**
      DD. *St. tinged brown-purple.*
        E. *Bearing bulblets.*
          F. *Burmese species*.......... 5. **sulphureum**
          FF. *Chinese species*.......... 6. **Sargentiæ**
        EE. *Not bearing bulblets* .... 7. **regale**
AA. *Tube gradually narrowing from base to neck.*
  B. *Lvs. scattered, with 3–5 or more nerves.*
    C. *Fls. pure white*................. 8. **candidum**
    CC. *Fls. white or yellow, tinged purple.*
      D. *Anthers reddish brown.*
        E. *Bulb globular*................ 9. **odorum**

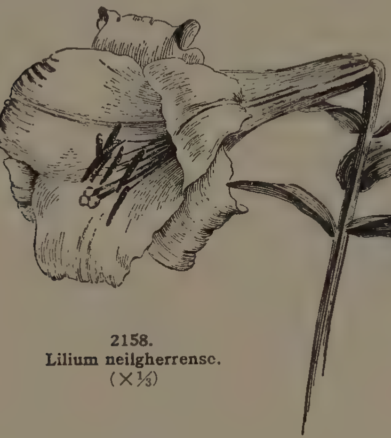
        EE. *Bulb oblate*................10. **Brownii**
      DD. *Anthers yellow*...............11. **nepalense**
    CCC. *Fls. pink.*
      D. *Anthers red*...................12. **iaponicum**
      DD. *Anthers yellow*...............13. **rubellum**
  BB. *Lvs. mostly verticillate, several nerved.*
    C. *Fls. white, pink or purple*........14. **washingtonianum**
    CC. *Fls. yellow*....................15. **Parryi**

1. **philippinénse,** Baker. Bulb globular or slightly oval, 1–2 in. diam., white, often tinged yellow: st. smooth, slender, 1–2 ft. high, green, sometimes dotted purple: lvs. 30–40, horizontal, 3–5 in. long, ⅛–⅙in. wide, upper ones slightly recurved: fls. usually solitary, rarely in pairs, 6–9 in. long, 4–6 in. wide, pure waxy white, tinged green near the base, delicately fragrant; anthers yellow. Late June, July. Philippine Isls. El. 3. B.M. 6250. I.H. 41:16. G.C. III. 30:47; 36:211. A.F. 23:907. Gng. 15:9. G.Z. 28, p. 145. Gn. 50:492.—Rather tender and capricious under cult.; in the northern states best suited for pots.

2. **longiflòrum,** Thunb. JAPANESE EASTER LILY. LONG-TUBED WHITE LILY. TRUMPET LILY. Bulb 2–4 in. diam., sometimes nearly globular, but more often of a peculiar oblate form, all the scales terminating together at the top or apex, which is flattened, while the base is narrower or constricted, color white or yellow: st. stout, smooth, 1–3 ft. high, bright green, sometimes tinged reddish brown near the base: lvs. 20–40, horizontal, or the upper ones semi-erect, 3–5 in. long, ⅓–½ in. wide: fls. 1–10, 4–6 in. long, nearly as wide, pure waxy white, often tinged green near the base; deliciously fragrant; anthers yellow. July to early Aug. China, Formosa, Liu Kiu Isls. and other parts of Japan. El. 7. B.R. 560. L.B.C. 10:985. Gn. 48, p. 386; 60, p. 44; 71, p. 495. G.C. III. 50:462; 51:43. A.F. 11:1311; 12:1104. A.G. 19:709. Gn. M. 10:112. C.L.A. 12:533. G. 35:827. G.W. 3, p. 43. Var. **fòliis álbo-marginàtis,** Hort., is similar, except the lvs. are paler green, edged creamy white, very rare. Var. **exímium,** Nichols. (*L. exímium*, Court., *L. floribúndum*, Hort., and *L. Hárrisii*, Carr.). BERMUDA EASTER LILY. A larger, stronger grower than the type, sometimes 4 ft. high, with 15–20 fls., 6–8 in. long. A.G. 18:297. A.F 12:143. Gn. 30:124; 43, p. 165; 45, p. 215; 46, p. 73; 47, p. 172; 49, p. 481; 52, p. 217; 60, p. 99; 66, p. 369; 68, p. 26. F.R. 1:679. G.C. III. 22:91; 43:180. R.H. 1883, p. 211; 1912, p. 456. G. 15:727; 17:29; 22:257; 23:613. Gn.M. 3:30; 5:73. J.H. III. 69:233. G.M. 47:375. Var. **insulàre,** Hort., is similar, but the perianth is said to be even longer. Magelhaes Archipelago, south of Japan. Gn. 61: suppl. Jan. 4. Var. **Wílsonii,** Hort. G. 11:131, var **multiflòrum,** Hort., A.F. 27:437; 35:477, and var. **gigantèum,** Hort., G.M. 52:65, are all nearly the same as var. *eximium*, but the sts. of the latter are heavily tinged reddish brown. Var. **Jàmesii,** Hort., a cross between the type and *L. Harrisii*, is not sufficiently distinct from either. Var. **Takésima,** Hort. (*L. Takésima*, Sieb.), sometimes called a distinct species, is evidently allied to *L. Brownii* and differs from the type in the st. being more heavily tinged and dotted brown, while the lvs. are longer and narrower and the fls. longer and not so widely expanded; when first opened there is a purplish brown midrib through the outside of each segm., while the 3 outer ones are also shaded chocolate. G.W. 15, p. 387. Var. **formòsum,** Hort., G. 4:187; 36:325, G.Z. 26; p. 195, from the island of Formosa, and var. **liukiuénsis,** Hort., from the Liu Kiu Isls., are similar, if not identical.—Although extensively grown as pot-plants for forcing, *L. longiflorum* and its vars. are seldom cult. in the open ground in the northern states. They are rather tender and, moreover, are not so permanent and long-lived as many others. After once flowering, the bulbs often have the exasperating habit of splitting up into 3 or 4

smaller ones, which require 2 or 3 years to bloom, or else they decay entirely, leaving a few small offsets.

3. **Wallichiànum,** Schult. Bulb globular or slightly oval, 2–3 in. diam., with broad, thick, reddish purple or brownish scales slightly notched at the edges: st. smooth, green, 4–6 ft. high: lvs. 50–60, erect or semi-horizontal, lower ones 6–9 in. long, ¼–½ in. wide, upper ones shorter and wider: fls. usually solitary, sometimes 2–3 together, 6–9 in. long, nearly as wide, deliciously fragrant, with waxy, creamy white segms., tinged golden yellow at the base inside and green outside; anthers yellow. Aug., Sept. Himalaya region from Nepaul to N. Burma. El. 4. B.M. 4561. Gn. 10:426. J.F. 1:105, 106, and p. 55. G.C. III. 28:10.—A magnificent species, but seldom cult. in this country.



2158. Lilium neilgherrense. (×⅓)

4. **neilghérrense,** Wight (*L. Métzii*, Steud. *L. neilghérricum*, Lem.). Fig. 2158. Bulb globular, 2–3 in. diam., with broad, thick scales, white or yellow, tinged purple or brown: st. smooth, 2–4 ft. high, the underground part often creeping along horizontally a foot or more before coming to the surface: lvs. 30–40, erect, 2–4 in. long, ½–1 in. wide: fls. 1–3, 6–8 in. long, nearly as wide, with waxy segms. of a rich buff color inside, fading to cream, almost white on the edge, outside faintly tinged purple; anthers yellow; the fragrance is delicately aromatic and distinct from that of any other lily. Aug., Sept. Neilgherry Mts. of S. India. El. 6. F.S. 22:2266, 2267. B.M. 6332. Gn. 27: 342. F.M. 1876:237. G.C. III. 30:53.—A beautiful species, but almost unknown in this country.

5. **sulphùreum,** Baker (*L. Wallichiànum* var. *supérbum*, Hort.). Bulb similar to that of *L. Wallichianum* but with smooth edges: st. smooth, 4–8 ft. high, green, tinged and dotted purple, bearing bulbils in the upper lf.-axils: lvs. 100–150, thickly scattered, horizontal, 2–4 in. long, ½–1 in. wide: fls. 1–4, 5–7 in. long, nearly as wide, deliciously fragrant, with waxy segms. of a sulfur-yellow color, fading to creamy white and tinged purple outside with purple midribs; anthers reddish brown. Aug., Sept. N. and E. Burma. B.M. 7257. Gn. 54, p. 259 (as *L. ochroleucum*); 66, p. 229; 71, p. 528; 72, p. 523. R.H. 1895, p. 541; 1913:180. G.C. III. 40:190; 51:19. J.H. III. 43:83; 59:37.—A magnificent, stately species, but rarely cult. Succeeds best in pots.

6. **Sárgentiæ,** Wilson (*L. leucánthum*, Hort. *L. Bròwnii* var. *leucánthum*, Hort.). Bulb similar to that of *L. sulphureum:* st. stout, smooth, 4–8 ft. high, green, tinged and dotted purple, bearing bulbils in the upper lf.-axils: lvs. 100 or more, thickly scattered, horizontal, 2–4 in. long, ½–1 in. wide: fls. 1–10 (usually 3–6), 5–6 in. long, nearly as wide, fragrant, waxy white inside, tinged yellow near the throat, outside heavily suffused reddish purple with deeper midribs; anthers reddish brown. Late July, Aug. W. China. Closely related to *L. sulphureum;* often confused with *L. Brownii* var. *leucanthemum*, to which it bears no resemblance. G.C. III. 51:385 (desc.) Gn. 77, p. 442; 69:234. J.H. III. 68:537. G.M. 48:579. Gn. W. 22: suppl. Oct. 21.—A magnificent lily, hardy as far north as Boston.

7. **regàle,** Wilson (*L. myriophýllum*, Hort., not Franch.). Bulb similar to that of *L. sulphureum:* st. 3–6 ft. high, smooth, stout, deep green, tinged and dotted purple: lvs. thickly scattered, 100 or more, deep green, horizontal, recurved, 3–6 in. long, ¼–½ in. wide: fls. 1–7 or more, 4–6 in. long, nearly as wide, deliciously fragrant, with waxy segms.; about a third of each one, near the base, inside, is bright canary-yellow, while the remainder of the interior is pure white, often suffused pink; outside they are white, tinged yellow at the base and with purple midribs, while the 3 outer ones are also heavily shaded purple; anthers reddish brown. July to early Aug. W. China. B.M. 8102. G.C. III. 38:328; 51:273; 53:416, 417. G.M. 55:416. Gn. 73, p. 397; 79, p. 27. F.S.R. 3, p. 331. C.L.A. 23:57. G. 32:57, 693; 35:537.—One of the most beautiful of all known lilies, the exquisite blending of tints and colors forming a charming contrast with the rich, deep green foliage. Highly recommended for general cult. both for pots and the open ground, where it is hardy, strong-growing and permanent as far north as Boston. *L. myriophyllum*, Franch., which is not in cult., differs in its oblate white bulb, its 3-nerved lvs., suberect nearly tubular fls., short pedicels and glabrous filaments.

8. **cándidum,** Linn. ANNUNCIATION LILY. BOURBON LILY. LENT LILY. MADONNA LILY. ST. JOSEPH'S LILY. Bulb globular or nearly so, 2–4 in. diam., white, tinged pale yellow: st. 2–4 ft. high, smooth deep green: lvs. 60–100 or more, lower ones horizontal, 6–9 in. long, 1½–2½ in. wide, appearing in autumn, upper ones gradually becoming smaller, those just below the infl. only 1 in. long, ½in. wide: fls. 3–20, 3–4 in. long and as wide, delicately fragrant, pure waxy white; anthers yellow. Late June, July. S. Eu. and S. W. Asia, from the island of Corsica to the Caucasus Mts. and N. Persia. El. 9. Gn. 45, p. 281; 53, p. 188; 56, p. 255; 66, p. 226; 71, p. 466; 74, p. 474; 79, p. 16. G.C. III. 21:161. G.M. 44:145; 51:698. Gng. 6:369; 13:5. F.E. 19:612. Gn. W. 14:41. G. 4:545. Gn.M. 4:28; 12:9.—Considered by many to be the lily of the Bible. It is of easy cult. in almost any soil or location and is also largely used for forcing. There are several varieties, all of which are rare, however, and none of them is superior to the type. Var. **fòliis álbo-marginàtis,** Hort., has the lvs. broadly edged pale yellow. Var. **flòre-plèno,** Hort. (var. *monstròsum*, Hort., var. *spicàtum*, Hort.), produces abortive fls. with white, dilated bracts; it is worth growing only as a curiosity. Var. **maculàtum,** Hort. (var. *striàtum*, Hort.), produces fls. which are streaked and veined purple on the outside; sometimes the lvs. also show the same variegation. Var. **peregrìnum,** Linn. (var. *byzantìnum*, Hort.), is of more slender growth than the type, with purple-tinged sts., narrower lvs. and narrower, longer perianth-segms. Var. **speciòsum,** Hort., is of smaller growth than the type, with purple-tinged sts. and comes into bloom about 2 weeks later; otherwise it is similar.

9. **odòrum,** Planch. (*L. Cólchesteri*, Hort. *L. colchesterénse*, Wallace). Fig. 2159. Bulb globular, 2–3 in. diam., white or pale yellow: st. smooth, 1–3 ft. high, glaucous-green, spotted purplish brown, darker at the base: lvs. 12–20, horizontal or semi-erect, 3–4 in. long, ⅔–1 in. wide, glaucous-green, tinged brown when young: fls. usually solitary, sometimes 2–3 together, 6–8 in. long, nearly as wide, with waxy segms., golden yellow inside, fading to creamy yellow, while the outside is tinged reddish brown; anthers reddish brown; the fragrance is rich

and delicious, similar to that of the Cape jasmine. July to early Aug. Japan, Korea and China. El. 14. B.M. 1591. L.B.C. 5:438. G.C. III. 43:316; 48:175. Gn.M. 2:174. Gn.W. 26:187. G.M. 44:467. G. 22:199. Also J. H. III. 62:221; G. 28:467; G.M. 50:58 (all as var. *Colchesteri*). Also G.C. III. 30:64; Gn. 66, p. 244 (as var. *colchesterense*). G.C. III. 30:54, and J.H. III. 43:63 (as var. *Alexandræ*). (See supplementary list.)—A lily of many names, often confused with *L. Brownii*, *L. japonicum*, and so on. It is quite rare, but is of easy cult., both in pots and open ground.

10. **Bròwnii,** Poit. Bulb of the same size and peculiar oblate form as that of *L. longiflorum*, but usually tinged and dotted reddish purple: st. smooth, 2–3 ft. high, deep reddish brown at the base and bare of lvs. for 6–8 in., upper part deep green, tinged and spotted reddish brown: lvs. 25–50, horizontal or semi-erect, recurved, 3–5 in. long, ½–¾in. wide, green, edged brown when young: fls. usually solitary, sometimes 2–4 together, 6–8 in. long, nearly as wide, delicately fragrant, with waxy segms. creamy white inside, fading to pure white and tinged yellow at the base; outside they are white, with purple midribs, while the 3 outer ones are also heavily tinged purple; anthers reddish brown. July, to early Aug. W. China. El. 8. Gn. 29:350 (as *L. japonicum*); 38, p. 173; 47, p. 97; 60, p. 201; 62, p. 299; 76, p. 552; 77, p. 94; 79, p. 15. G.C. III. 42:67. G. 10:161. Gn.W. 20:661. Gng. 4:193. F.S. 21:2248, 2193 (as *L. japonicum Colchesteri*).—Hardy and of easy cult., but the bulbs, like those of *L. longiflorum*, are very liable to decay if surplus water collects in the peculiar cup-like depression at the base of the scales. Especially good for pots. The var. **chloráster,** Hort., has narrower lvs. and the fls. are tinged green, not purple. Gn. 47:97 (as var. *leucanthum*). Var. **leucánthemum,** Hort., has entirely green sts. and yellow-tinted fls. B.M. 7722. G. 28:567; 31:561. G.C. III. 49:264. Both of these are very rare, while the vars. **platyphýllum,** Hort., and **virídulum,** Hort., which have been mentioned, are not in cult. Var. **kansuénse,** Hort., is mentioned in recent horticultural literature.

11. **nepalénse,** D. Don (*L. ochroleùcum*, Wall.). Bulb similar to that of *L. neilgherrense:* st. smooth, 2–4 ft. high: lvs. 30–50, erect or nearly so, 2–4 in. long, ½–¾in. wide: fls. 1–7, semi-horizontal or nearly pendulous, 4–5 in. long, nearly as wide, delicately fragrant, about half of each segm. at the base, inside, is bright, reddish purple, while the remainder of the interior is pale citron-yellow, next to the solid purple there are usually a few spots of the same color on the yellow background; anthers yellow. Aug., Sept. Himalaya Mts. from Nepaul to N. Burma. El. 5. B.M. 7043. R.B. 22:3. Gn. 35:54; 78, p. 159. G.W. 2, p. 93. J.H. III. 54:349. Gn.W. 12:785.—Rarely seen in cult. except by specialists, and only suitable for pots.

12. **japónicum,** Thunb. (*L. Kràmeri*, Hook., f.; see B. M. 7634. *L. japónicum* var. *ròseum*, Hort.). Bulb globular or slightly spherical, 1–2 in. diam., white or pale yellow sometimes tinged red or purple: st. smooth, 2–4 ft. high, green, tinged and dotted deep purple, lower part bare of lvs.: lvs. 15–20, horizontal or semi-erect, 6–9 in. long, ½–¾in. wide: fls. 1–7, 5–7 in. long and as wide, deliciously fragrant, usually of a bright pure rose-pink color, both inside and out, but sometimes deepening to rose-purple or fading to pale blush, nearly white; anthers red. June to early July. Japan. B.M. 6058. F.M. 1874:105. F. 1874:13. F.S. 20:2061-62. G. 18:95. Gn. 60, p. 45. G.Z. 18:113.—A beautiful lily, thought by some authorities to be a wild or natural hybrid between *L. auratum* (which the bulb and plant somewhat resembles) and another species, probably *L. odorum*. Unfortunately, it is delicate and capricious under cult., the bulbs decaying very easily from surplus moisture; although quite hardy, they can rarely be established in the open ground for any length of time and are best grown in pots or coldframes.

13. **rubéllum,** Baker. Bulb quite similar to that of *L. japonicum*, but more oval in shape: st. 1–2 ft. high, smooth, green, spotted and tinged purple, lower part bare of lvs.: lvs. 15–20, horizontal, 4–5 in. long, ¾–1 wide: fls. 1–8, 3–4 in. long and as wide, fragrant, of the same color variations as *L. japonicum;* anthers yellow or orange. June to early July. Japan. Gn. 54:410; 60, p. 43; 77, p. 95. G.C. III. 23:335; 30:42; 46:168. G.M. 41:477; 44:466. A.G. 20:31. Gn.W. 20:854. Gn.M. 2:175. G. 28:245. F.R. 8:97.—Allied to *L. japonicum* but possesses a better constitution, being rather more robust and permanent.

14. **washingtoniànum,** Kellogg (*L. Bártrami*, Nutt.). Bulb semi-rhizomatous, oblique, prolonged laterally to a length of 6–8 in., scales large, broad, loosely arranged, grayish white or pale yellow, sometimes tinged and dotted purple: st. stout, smooth, 3–6 ft. high: lvs. horizontal or semi-erect, glaucous-green, 3–4 in. long, ⅔–1 in. wide, usually in 6–9 whorls, each containing 5–12 lvs., with a few scattered ones above: fls. in racemes of 2–20, 2½–4 in. long, nearly as wide, deliciously fragrant, white, slightly tinged and dotted reddish purple or lilac inside and more heavily suffused purple outside; anthers yellow or orange. Late June, July. Calif., along the Sierra Nevada Mts. and Coast Range. El. 10. Gn. 20:484; 27, p. 344; 61, pp. 54, 55; 71, p. 139. J.H. III. 33:113.—A beautiful and stately species when well grown, but in the N. E. is rather capricious and often fails to succeed in the open ground. The var. **purpùreum,** or var. **purpuráscens,** Hort. (*L. purpùreum*, Mast.), is of more slender growth and smaller in every way, 2–3 ft. high, with lvs. 1–2 in. long, while the fls. are semi-erect and borne in umbels of 4–8; color white, faintly tinged lilac and spotted purple internally when first opened, soon changing to uniform lilac-purple. El. 11. F. S. 19:1975-76. G.C. III. 30:59. C. L. A. 5:43. Var. **rubéscens,** Hort. (*L. rubéscens*, Wats.), has a smaller, more globular bulb than the typical species, a more slender st. 3–5 ft. high, narrower lvs. and a raceme of 4–12 smaller, semi-erect fls., with more reflexed segms.; color white, tinged rose-pink, unspotted, changing to uniform rose-purple. Both these varieties are perhaps entitled to rank as distinct species. Var. **mìnus,** Hort., is mentioned. G. 29:137.

2159. Lilium japonicum. (×⅓)

15. **Párryi,** Wats. Bulb a scaly rhizome, 2–4 in. long, often irregular in shape, thickly covered with small scales, which are sometimes jointed and of a white or pale yellow color, rarely tinged pink or purple: st. slender, smooth, 2–5 ft. high: lvs. horizontal, 4–6 in. long, ⅓–½ in. wide, lower ones usually whorled, upper ones scattered: fls. 1–10, 2–4 in. long, as wide, delicately fragrant, of pure lemon-yellow color, more or less spotted internally purplish brown; anthers orange-red. Late June, July. San Bernardino Mts. of S.

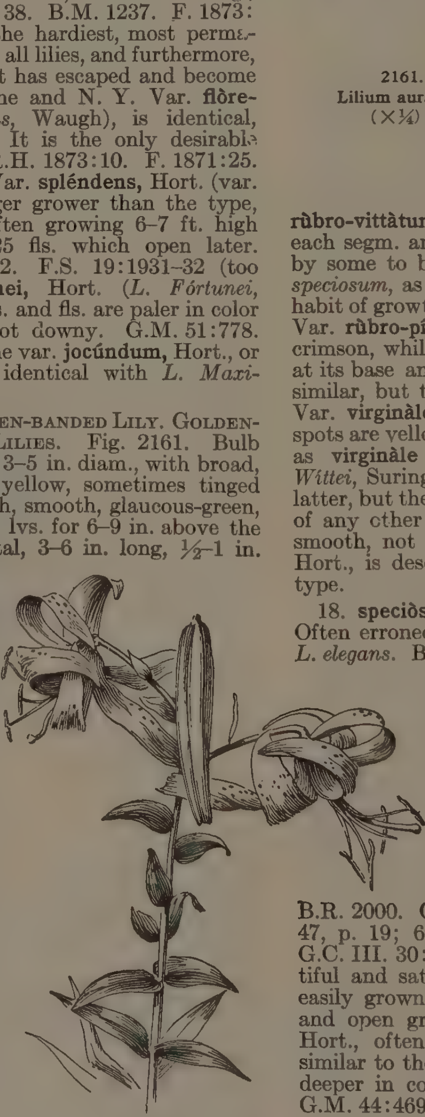
Calif. El. 12. B.M. 6650. I.H. 33:595. Gn. 18:652 (not typical); 49, p. 410; 60, p. 337. G.C. III. 18:209 (habit not correctly shown); 30:57; 55:217. G. 19:133. —A beautiful species, rather capricious and tender under cult., but usually succeeding well under the same conditions as *L. canadense* and *L. superbum.*

SUBGENUS II. ARCHELIRION.

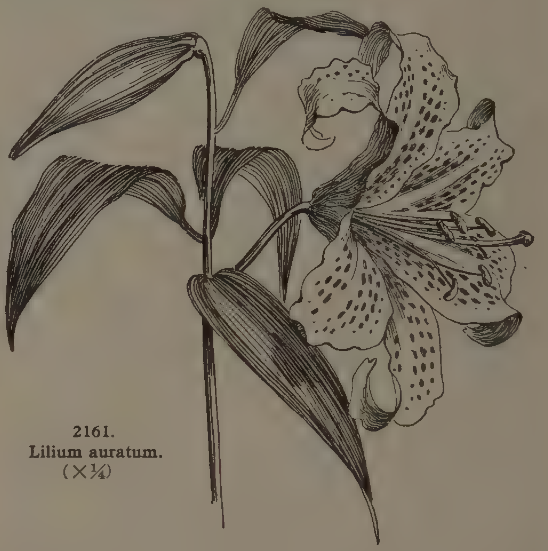
A. *Lvs. sessile*........................16. **tigrinum**
AA. *Lvs. shortly stalked.*
  B. *Fls. white or pink.*
    C. *Borne horizontally*..............17. **auratum**
    CC. *Becoming nearly pendulous*......18. **speciosum**
  BB. *Fls. reddish yellow*..............19. **Henryi**

16. **tigrìnum**, Ker-Gawl (*L. sinénse*, Hort.). TIGER LILY. Fig. 2160. Bulb spherical, 2–4 in. diam., white or pale yellow, sometimes tinged red or purple: st. stout, 2–4 ft. high, deep purplish brown, covered with white or grayish cobweb-like down and producing deep purple bulbils in the upper lf.-axils: lvs. 75–100 or more, deep green, 2–4 in. long, ¼–½in. wide: fls. 1–15, 3–5 in. diam., with bright salmon-red segms.; spotted purplish black and reflexed to the st.; anthers red. Aug., Sept. China and Japan. El. 38. B.M. 1237. F. 1873: 13. G.M. 44:468.—One of the hardiest, most permanent and most easily grown of all lilies, and furthermore, one of the most beautiful. It has escaped and become naturalized in parts of Maine and N. Y. Var. **flòre-plèno,** Hort. (var. *plenéscens*, Waugh), is identical, except the fls. are double. It is the only desirable double-fld. lily in cult. R.H. 1873:10. F. 1871:25. F.S. 19:1995. G.Z. 20:17. Var. **spléndens,** Hort. (var. *Lèopoldii*, Hort.), is a stronger grower than the type, and larger in every way, often growing 6–7 ft. high and bearing as many as 25 fls. which open later. Gn.W. 20:907. Gn. 27:152. F.S. 19:1931–32 (too dark-colored). Var. **Fórtunei,** Hort. (*L. Fórtunei*, Lindl.), is similar, but the lvs. and fls. are paler in color and the sts. are smooth, not downy. G.M. 51:778. Gn. 74, p. 586, 77, p. 73. The var. **jocúndum,** Hort., or var. *Líshmanii*, Moore, is identical with *L. Maximowiczii.*

17. **auràtum,** Lindl. GOLDEN-BANDED LILY. GOLDEN-RAYED LILY. QUEEN OF LILIES. Fig. 2161. Bulb spherical or nearly globular, 3–5 in. diam., with broad, thick scales, white or pale yellow, sometimes tinged red or purple: st. 3–6 ft. high, smooth, glaucous-green, often tinged purple, bare of lvs. for 6–9 in. above the surface: lvs. 20–50, horizontal, 3–6 in. long, ½–1 in. wide: fls. 1–15, 6–10 in. diam., deliciously fragrant, white spotted crimson, with a yellow band or midrib extending the whole length of each segm.; anthers red. Blooms late July, Aug. Japan. El. 15. Gn. 16:212; 39, p. 455; 50, p. 148; 60, p. 48; 64, p. 196; 65, p. 41; 70, p. 125; 71, pp. 395, 515, 550; 72, p. 443; 75, p. 138; 79, p. 4. G.C. III. 25:303; 54:269. G.M. 44:464, 593; 55:91. G. 20:503; 35:597. J.H. III. 53:37; 68:43. A.F. 7:43; 35:105. C.L.A. 12: 532; 14:45. H.F. II. 6:104. G.W. 6, p. 158. G.Z. 9:2. R.B. 21:25. F.M. 1871:514. R.H. 1867:371; 1875:10. B.M. 5338. A.G. 20:525.—Rather capricious under cult., often disappearing in a year or two, but so gorgeously beautiful that it should be generally grown, even if frequent renewal is necessary. One of the best lilies for pots. Var. **platyphýllum,** Hort. (var. *macránthum*, Hort.), is superior to the type, being a larger, stronger grower, sometimes 8–10 ft. high, with fls. a foot or more across, of the same color, but only slightly spotted. G. 30:609; 35:645; 36:715. Gn. 63, p. 95. Gn.W. 20:1027. Var. **rùbro-vittàtum,** Hort., has a wide crimson band through each segm. and numerous crimson spots; it is thought by some to be a hybrid between *L. auratum* and *L. speciosum,* as it resemble the latter more in bulb and habit of growth. Var. **cruéntum,** Hort., is quite similar. Var. **rùbro-píctum,** Hort., produces white fls. spotted crimson, while the band through each segm. is yellow at its base and red at the end. Var. **píctum,** Hort., is similar, but the yellow portion of the band is absent. Var. **virginàle,** Hort., resembles the type, except the spots are yellow; there is also an unspotted form, known as **virginàle álbum,** Hort. Var. **Wíttei,** Hort. (*L. Wíttei*, Suring.), produces fls. of the same color as the latter, but the segms. are shorter and broader than those of any other variety, and, unlike all others, they are smooth, not papillose, inside. El. 16. Var. **Tashíroi,** Hort., is described as a dwarf, large-fld. form of the type.



2160. Lilium tigrinum. (×¼)



2161.
Lilium auratum.
(×¼)

18. **speciòsum,** Thunb. SHOWY LILY. Fig. 2162. Often erroneously called *L. lancifolium,* a synonym of *L. elegans.* Bulb globular, 3–4 in. diam., reddish purple or brownish, rarely yellow or orange; scales broad and thick: st. 2–4 ft. high, smooth, green, often tinged and dotted purple: lvs. 12–25 or more, horizontal, 3–6 in. long, ½–1½ in. wide: fls. 1–10, 4–6 in. diam., delicately fragrant, with segms. often reflexed to the st.; they are white, suffused rose-pink in the center and spotted blood-red, with a green stripe at the base; anthers red. Late Aug., Sept. Japan. El. 13. B.M. 3785. B.R. 2000. Gn. 25:82; 33, p. 289; 45:90, and p. 91; 47, p. 19; 60, p. 408; 63, p. 108. R.H. 1843:492. G.C. III. 30:241. G. 5:457.—One of the most beautiful and satisfactory of all lilies, robust, permanent, easily grown and highly recommended for both pots and open ground. Vars. **ròseum,** Hort., and **rùbrum,** Hort., often catalogued as distinct, are really very similar to the type, but the fls. of the latter are rather deeper in color. Gn. 36:434; 60, p. 313; 70, p. 187. G.M. 44:469. Gn.M. 2:115. Gn.W. 15:7. G.W. 15, p. 596. Var. **Kaèmpferi,** Hort., var. **purpuràtum,**

Hort., and var. **Schrymákersi,** Hort., are all similar to var. *rubrum.* Var. **macránthum** and var. **multiflòrum,** Hort., are also similar, but are of larger, stronger growth and more free-flowering. Var. **Melpómene,** Hort., is of somewhat different habit of growth than the type and has much deeper-colored fls. which are of a rich carmine-crimson, spotted blood-red and narrowly edged white. Var. **magníficum,** Hort., is closely allied to var. *Melpomene,* but is larger in every way, of stronger growth and comes into bloom a little earlier. J.H. III. 68:125. G. 27: 469; 33:689, 692. Var. **cruéntum,** Hort., is a dwarfer form of var. *Melpomene,* flowering two weeks later. Var. **gloriosoìdes,** Baker, differs from the type in its narrower lvs., much twisted gloriosa-like segms. and scarlet spots. Var. **álbum,** Hort. (var. *albiflòrum,* Hook.), has deep brown bulbs, brown-tinged sts. and buds and unspotted white fls. slightly suffused pink; anthers reddish brown. P.M. 8:127. Gn.W. 23, suppl. May 19. Var. **álbum nòvum,** Hort., has pure white fls. with yellow anthers. Var. **Kraëtzeri,** Duch., often sold as var. *album,* is quite distinct, differing in its yellow bulbs, entirely green st., more pointed, brighter green lvs. and green-tinged buds; the fls. are pure white with a pale green stripe halfway down the center of each segm. and reddish brown anthers. G. 11:69; 15:97. Var. **vestàle,** Hort., is similar. Var. **punctàtum,** Lem., has yellow bulbs, entirely green sts. and white or pale blush fls. spotted rosy crimson. It is of more delicate constitution than the other varieties. Var. **prǽcox,** Hort., is similar, if not identical. There are also several other horticultural forms, but they are not sufficiently distinct to be recognized.

2162. Lilium speciosum. (×⅓)

19. **Hényri,** Baker. Fig. 2163. Bulb similar to that of *L. speciosum,* but often larger, deep reddish purple: st. smooth, 4–8 ft. high, deep green, heavily tinged and spotted purplish brown: lvs. 60–100, horizontal, 3–6 in. long, ¾–1½ in. wide, upper ones shorter and recurved: fls. 1–20, 3–4 in. diam., inodorous, bright orange-yellow, slightly spotted reddish brown and with a green band at the base of each segm.; anthers orange-red. Aug., Sept. Cent. China. B.M. 7177 (too light-colored). Gn. 40:422; 55, p. 233; 60, p. 336. G.C. III. 8:380. J.H. III. 42:131. R.H. 1903:232. G. 35:655.—One of the very best of all lilies for general cult., hardy, robust, long-lived and easily grown in almost any soil and situation. Sometimes called the yellow *L. speciosum;* although it resembles that species in bulb and form of fls., it is entirely distinct in habit of growth.

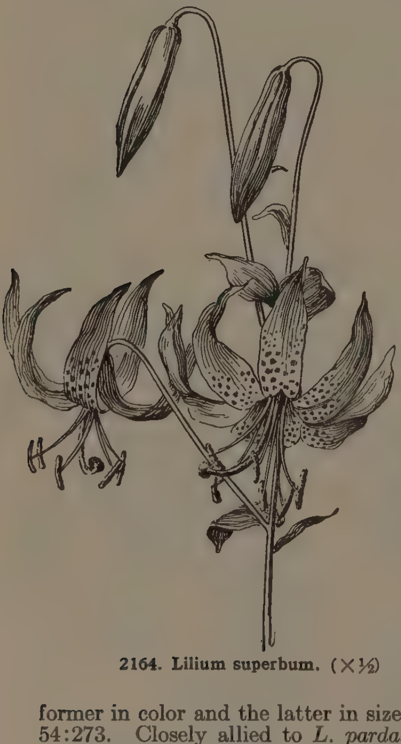
20. **supérbum,** Linn. AMERICAN TURK'S-CAP LILY. SWAMP LILY. Fig. 2164. Bulbs rhizomatous, borne an inch or two apart on stout rhizomes, globular or nearly so, 1–2 in. diam., white, often tinged red or pink; scales small, thick, sometimes jointed: st. stout, smooth, 3–8 ft. high, green, sometimes tinged purple, usually bare of lvs. for 5–6 in. above the surface: lvs. horizontal, 2–5 in. long, ½–¾ in. wide, usually in 3 or 4 whorls of 4–10 lvs. each, with a few scattered ones above: fls. 1–40, 3–4 in. diam., with segms. reflexed to the st., of a brilliant orange-scarlet, shaded yellow and spotted purplish brown at the base; anthers red. Late July to early Sept. New Bruns. to Ont., Minn., Mo., and Ga. El. 26. B.M. 936. L.B.C. 4:335 (as *L. autumnale*). Gn. 30:8 and p. 9; 38:506. Gn.W. 22, suppl. Nov. 4. —The most magnificent and showy of native North American species, well worthy of extensive cult. It is considerably variable and there are intermediate forms between *L. superbum* and *L. canadense.*

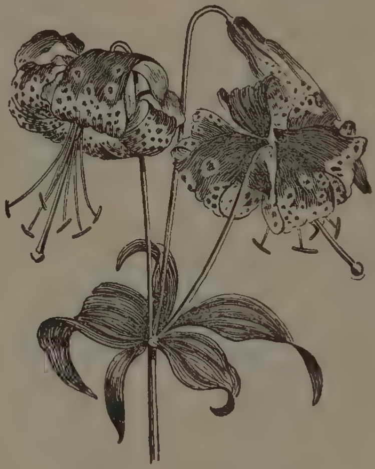
21. **caroliniànum,** Michx. (*L. autumnàle,* Lodd. *L. Michaùxii,* Poir. *L. Michauxiànum,* Schult. *L. supérbum* var. *caroliniànum,* Chapm.). SOUTHERN SWAMP LILY. Allied to *L. superbum,* but the bulbs more nearly resemble those of *L. pardalinum:* st. smooth, slender, 2–4 ft. high: lvs. horizontal, deep green, 2–3 in. long, ¾–1 in. wide, usually in 5–6 whorls, with a few scattered ones above and below: fls. 1–3, 3–4 in. diam., delicately fragrant, of the same color as *L. superbum,* but with a paler, almost white throat. Late July, Aug. Va. to Fla. and La.—Of easy cult., but rather more tender and not so desirable as *L. superbum.*

2163. Lilium Henryi. (×¼)

22. **pardalìnum,** Kellogg. Leopard Lily. Panther Lily. Fig. 2165. Bulb a scaly rhizome, quite similar to that of *L. Parryi*, but more branching and irregular in form: st. 3–6 ft. high, smooth, pale green: lvs. horizontal, 3–4 in. long, ¾–1 in. wide, usually in 3 or 4 whorls of 9–15 lvs. each, with a few scattered ones above and below: fls. 1–30, 2–4 in. diam. with segms. reflexed to the st., about half of each one, at the base, is bright yellow, spotted brownish purple, while the remainder, at the end is bright orange-scarlet; anthers red. Late June to early Aug. Sierra Nevada Mts. of Calif. El. 28, 29. F.M. 1872:33 (as *L. washingtonianum*). Gn. 20:526. G. 32:463. J.H. III. 49:147; 51:79. Gn. M. 9:236. —This lily is the best and most easily grown Calif. species for general cult.; hardy, robust, and permanent. Var. **angustifòlium,** Kellogg, is identical, except the lvs. are much narrower, and it is of more slender growth: it is sometimes confused with *L. Roezlii*. Var. **califórnicum,** Hort. (*L. califórnicum*, Lindl.), has smaller lvs., mostly scattered, and larger, more richly colored fls. G.C. III. 30:43. Var. **pallidifòlium,** Baker (var. *pubérulum*, Leicht.), has paler green lvs. and smaller, paler-colored fls. than those of the type, not so thickly spotted. Var. **Robinsoniànum,** Moore, is a stronger grower than the type, sometimes 8–9 ft. high, with mostly scattered lvs. and larger, more richly colored fls. Var. **lùteum,** Hort., produces pure yellow fls., spotted brownish purple; in other respects it is the same as the type.—There are also several other rather indistinct so-called vars. and an unnamed hybrid between *L. pardalinum* and *L. Humboldtii*. Another hybrid between *L. pardalinum* and *L. Parryi*, called *L. Búrbankii*, Hort., produces fls. resembling those of the former in color and the latter in size and shape. G.M. 54:273. Closely allied to *L. pardalinum* is *L. parviflòrum*, Hook. (*L. Sàyi*, Nutt., *L. pardalìnum* var. *mìnus*, Hort.), but the fls., which are of the same color, are smaller and are solitary or 2 or 3 are borne together. June, July. Vancouver Isl. to N. Calif. along the seacoast. Rather capricious under cult.



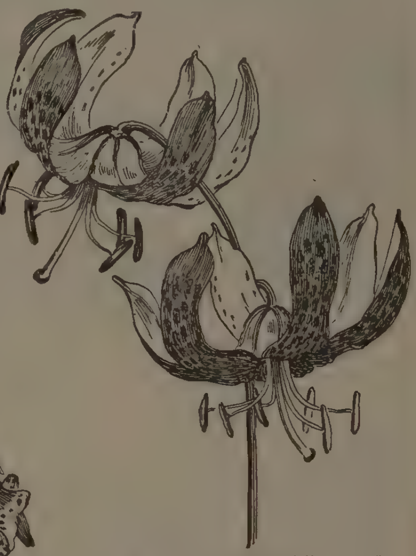
2164. Lilium superbum. (×½)



2165. Lilium pardalinum. (×⅕)

23. **Roèzlii,** Regel (*L. Hártwegii*, Baker). Bulb similar to that of *L. pardalinum:* st. smooth, 2–5 ft. high: lvs. horizontal, 2–5 in. long, ¼–⅓in. wide, usually scattered, sometimes a few of the upper or middle ones whorled: fls. 1–10, 2–3 in. diam., bright orange-yellow tipped red or scarlet and spotted brownish purple; anthers red. Late June to early Aug. Santa Cruz Mts. of Calif.—Allied to *L. pardalinum* and of the same easy cult.

24. **Húmboldtii,** Roezl & Leicht. (*L. Bloomeriànum*, Kellogg). Fig. 2166. Bulb semi-rhizomatous, oblique, somewhat similar to that of *L. washingtonianum*, but with larger, broader scales: st. stout, 4–6 ft. high, smooth or slightly pubescent, deep green tinged and spotted purplish brown, clothed with lvs. from the ground upward: lvs. horizontal, glaucous-green, 3–5 in. long, ¾–1 in. wide, usually in 4–5 whorls of 10–15 lvs. each: fls. 1–30, 4–5 in. diam., bright orange-yellow, spotted deep purple-brown; anthers red. Late June to early Aug. Sierra Nevada Mts. of Calif. El. 32. F.S. 19:1973–34. Gn. 20:568. J. H. III. 42:177; 62:167. G. 2:243; 33:121. C.L.A. 5:45.—A magnificent species, very stately and beautiful; although rather capricious under cult., it usually succeeds fairly well. Var. **magníficum,** Hort., is even superior, being a stronger, more robust grower, often 8 or 9 ft. high, with larger, more richly colored fls., often tinged reddish purple. Var. **pubérulum,** Hort. (*L. pubérulum*, Duch.), is identical with the type, except the st. and under side of the lvs. are more densely pubescent. Var. **ocellàtum,** Kellogg, from the island of Santa Rosa, has a smaller, more globular bulb and brighter green lvs. than the type: the fls. are of the same color, but each purple spot is surrounded with a red circle or eye.



2166. Lilium Humboldtii. (×⅕)

25. **columbiànum,** Hanson (*L. nítidum*, Hort. *L. oregonénse*, Hort.). Bulb similar to that of *L. Humboldtii*, but smaller and more globular: st. smooth, 2–4 ft. high: lvs. horizontal, 1½–3 in. long, upper ones scattered, lower ones in whorls of 4–5: fls. 1–12, 2–3 in. diam., bright orange-yellow, spotted purplish brown; anthers red. Late June to early Aug. Ore., Wash., and Brit. Col.—Smaller in every way, but closely related to *L. Humboldtii* and perhaps should only be ranked as a variety of it.

26. **Kélloggii,** Purdy. Bulb similar to that of *L. columbianum:* st. smooth, slender, 2–4 ft. high: lvs. mostly verticillate, partly scattered: fls. 1–15, 1½–2 in. diam., delicately fragrant, with segms. reflexed to the st.; color pink, spotted purplish black, changing to deeper rosy purple; anthers orange or red. Late June, July. N. W. Calif. Gn. 59, p. 330; 62, p. 200; 64, p. 16.—Very dainty and graceful.

27. **Mártagon,** Linn. European Turk's-Cap Lily. Turban Lily. Fig. 2167. Bulb oval, 2–3 in. long, 1–2 in. wide, bright yellow; scales thick, narrow, sharply pointed: st. 3–6 ft. high, smooth, or upper part slightly pubescent, green, often spotted purple: lvs. horizontal, deep green, 3–6 in long, 1–1½ in. wide, usually in 2–4 whorls of 6–9 lvs. each, with a few scattered ones above: fls. 3–20, 2–3 in. diam., dull claret-purple, spotted purplish black; segms. thick, waxy, reflexed to the st. and slightly papillose at the base; anthers red; the fls. emit a nauseous, disagreeable odor. Late June, July. Cent. and S. Eu. from Spain to S. W. Siberia. Fl. 33. B.M. 872 (as *L. pennsylvanicum*); 1634. F.S. 20:2127. F.M. 1874:136. Gn. 23:32; 38, p. 393; 44:260 (as *L. Dalhansonii*). Var. **hirsùtum,** Hort., is identical, except the sts. are more densely pubescent. Var. **flòre-plèno,** Hort., produces double or semi-double fls. Var. **dalmáticum,** Hort. (*L. dalmáticum,* Malay), from Dalmatia, often grows 6–7 ft. high, with 5–7 whorls of lvs.: and 12–40 fls. which are of a deeper, richer purple, almost black, and only slightly spotted; the buds are enveloped in white, cottony down. Var. **Cattáneæ,** Hort., is almost identical, but the fls. are slightly paler in color. Var. **álbum,** Hort. (var. *glàbrum,* Spreng.), produces pure white fls. with yellow anthers; the sts. are smooth and the lvs. brighter green than those of the type. G.C. III. 54:63.—There are also varieties with flesh- and lilac-colored fls. All the forms of *L. Martagon* are hardy, robust and of the easiest cult., but var. *album* and var. *dalmaticum* are far superior to the type.

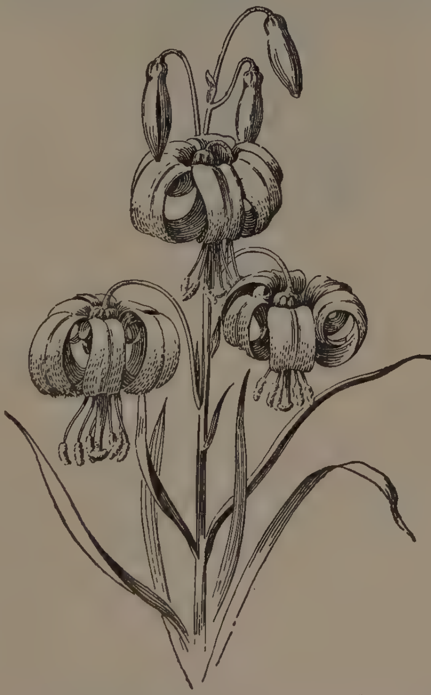
2167. Lilium Martagon. (×⅓)

28. **avenàceum,** Fisch. Bulb globular, 1–1½ in. diam., bright yellow, rarely tinged pink or purple; scales long, narrow, sharply pointed and jointed, the upper part, when broken off, resembling oats, whence the specific name: st. 1½–2 ft. high, smooth, bare of lvs. near the base: lvs. horizontal or semi-erect, 3–4 in. long, ½–1 in. wide, usually in 1 or 2 whorls of 6–9 lvs. each near middle of st. with a few scattered ones above: fls. 2–10, slightly fragrant, bright orange-yellow shaded red and more or less spotted deep purple; anthers red. June, early July. Manchuria, Kamchatka, Kurile Isls. and N. Japan. Gn. 24, p. 85.—Very rare and only desirable for collectors or specialists. The bulbs are delicate and easily break to pieces when handling.

29. **Hánsonii,** Leicht. Golden Turk's-Cap Lily. Japanese Turk's-Cap Lily. Fig. 2172. Bulb nearly globular, 2–3 in. diam., white or pale yellow, often tinged purple: st. smooth, 3–5 ft. high: lvs. horizontal, 4–5 in. long, ¾–1 in. wide, usually in 1–3 whorls near middle of st. with a few scattered ones above and below: fls. 1–10, 1½–2½ in. diam., slightly fragrant, with thick, waxy segms. of a bright golden yellow, spotted purplish brown; anthers orange-red. June, early July. Japan. El. 34. B.M. 6126 (as *L. maculatum*). Gn. 29, p. 287. R.H. 1883, p. 296. Gn.W. 22, suppl. April 8.—One of the best and most beautiful lilies for general cult., easily grown, robust and permanent. *L. Márhan,* Hort., is a garden hybrid between *L. Martagon* var. *album* and *L. Hansonii;* it resembles the former in habit of growth, but the fls. are of the same shape, size and thick, waxy texture as those of the latter; color bright orange-yellow, veined, shaded and spotted reddish brown. A similar hybrid between *L. Martagon* var. *dalmaticum* and *L. Hansonii* is known as *L. Dalhánsonii,* Hort. The fls. are not so bright in color, however.

30. **polyphýllum,** D. Don (*L. punctàtum,* Jacquem.). Bulb oblong, 2–3 in. long, 1–1½ in. wide, with long, narrow, white scales, closely clasped together: st. smooth, 2–4 ft. high: lvs. 40–60, scattered, or the lower ones rarely whorled, erect, 4–5 in. long, ½–¾ in. wide: fls. 1–10, 1½–2 in. diam., deliciously fragrant, pale creamy yellow, tinged and dotted purple; anthers red. June, July. W. Himalayas. I.H. 32:565.—Very rare and only suitable for specialists.

31. **monadélphum,** Marsh & Bieb. (*L. cólchicum,* Stev. *L. Loddigesiànum,* Roezl & Schult.). Bulb quite similar to that of *L. Martagon,* but often larger and tinged purple: st. stout, 3–6 ft. high, usually slightly pubescent: lvs. 30–40, horizontal or semi-erect, 2–4 in. long, ½–1 in. wide: fls. 1–30, 3–5 in. diam., with waxy segms. of a rich golden yellow sometimes tinged purple and slightly, or not at all, spotted deep purple; anthers greenish or orange; the odor is rather disagreeable. June, early July. Caucasus Mts. and N. Persia. El. 36, 37. B.M. 1405. Gn. 75, p. 320. G.C. III. 16: 129. Gn.W. 22:528. J.F. 2:204.—One of the most stately and beautiful of all lilies, succeeding well in almost any soil or situation and highly recommended for general cult. Var. **Szovitziànum,** Hort. (*L. Szovitziànum,* Fisch. & Lall.). Produces larger fls. with broader, less reflexed segms. of a lemon- or canary-yellow color, more thickly dotted purple and with reddish brown anthers; the filaments are entirely free or separate, whereas in the type they are supposed to be joined or united at their base, although this is not always the case. Gn. 9:204; 39:242; 59, p. 407; 64, p. 316. G.C. III. 48: 37. Gn.W. 21:522. G. 4:295; 27:373; 32:783. Var. **Lédebouri,** Baker, resembles the type, but is dwarfer, with 80–100 narrower lvs. and narrower perianth-segms.



2168. Lilium pomponium. (×½)

32. **carniólicum,** Bernh. Bulb oval, 1½–2 in. long, 1–1½ in. wide, white or pale yellow, tinged red or

purple; scales broad, closely imbricated: st. 2–3 ft. high, green, slightly pubescent: lvs. 30–40, erect or nearly so, 2–3 in. long, ½–¾ in. wide: fls. 1–10, 1½–2 in. diam., orange-red dotted purple-black; segms. waxy, reflexed to the st. and papillose inside; anthers orange; the odor is rich and heavy but not unpleasant. June, early July. Carniolia, Bosnia, Dalmatia and vicinity. El. 45.—An easily grown species, but rarely seen in cult. There is also an unspotted variety, var. **unícolor,** Hort.

33. **chalcedónicum,** Linn. (*L. rùbrum,* Parkin.). Scarlet Turk's-Cap Lily. Bulb similar to that of *L. monadelphum:* st. 2–4 ft. high, green, tinged purple, covered with white down: lvs. 100 or more, lower ones horizontal, 2–6 in. long, ⅙–¼ in. wide, upper ones smaller and more erect: fls. 3–6 or more, 2–3 in. diam., brilliant vermilion-scarlet, rarely slightly dotted purple; segms. thick and waxy, reflexed to the st. and papillose at the base; anthers scarlet; the odor is rather disagreeable. July, early Aug. Greece and the Ionian Isls. El. 43. F.S. 21:2160. B.M. 30. F.W. 1876:193. Var. **maculàtum,** Hort. (var. *excélsum,* Hort., var. *màjus,* Hort.), is a larger, stronger grower, while the fls. are usually solitary and more thickly dotted purple; very rare. Both are hardy and of easy cult. and should be more generally grown.

2169. Lilium canadense. (×⅓)

34. **pompònium,** Linn. (*L. rùbrum,* Lamb.). Little Turk's-Cap Lily. Fig. 2168. Bulb similar to that of *L. Martagon:* st. 1½–3 ft. high, furrowed or striated: lvs. 100 or more, lower ones horizontal, 2–4 in. long, ⅙–⅓in. wide, upper ones smaller and more erect: fls. 1–15, 1½–2 in. diam., brilliant scarlet, dotted purplish black; segms. thick and waxy, reflexed to the st. and thickly papillose at the base; anthers scarlet. June, early July. Alps of S. France and N. Italy. El. 46. Gn. 20:420. G.C. III. 8:51. Gn.W. 20:675. G.W. 3, p. 356.—A graceful handsome species of easy cult., but the strong, nauseous odor of the fls. is a factor against its popularity. The var. **vèrum,** Hort., is similar, but the lvs., when first unfolding are twisted or curled like a sickle and slightly edged white.

35. **pyrenàicum,** Gouan (*L. flàvum,* Lamb. *L. pompònium* var. *lùteum,* Hort. *L. pompònium* var. *pyrenàicum,* Baker). Yellow Turk's-Cap Lily. Resembles *L. pomponium,* to which it is closely related, but often grows 4 ft. high, with larger bulbs, wider lvs. and larger fls. of a pale lemon-yellow, dotted purplish black; anthers red. June, early July. Pyrenees Mts. of S. France and N. Spain. El. 47. There is an unspotted var. **unícolor,** Hort., and also another var. **aûreum,** Hort., with spotted fls. of a brighter, deeper golden yellow color.—*L. Jánkæ,* Kern., although found in Transylvania, 1,000 miles from the habitat of *L. pyrenaicum,* is very similar to it, but often grows taller, with slightly larger fls. and greenish yellow anthers, while the odor, instead of being nauseous, is quite agreeable, resembling honey.

36. **Leìchtlinii,** Hook. Bulb similar to that of *L. tigrinum,* but smaller and never tinged red or purple: st. 2–4 ft. high, smooth, green shaded brownish purple, the underground part often running along horizontally a foot or more before coming to the surface: lvs. 30–40, horizontal or semi-erect, 2–5 in. long, ¼–⅓in. wide: fls. 1–20, 3–4 in. diam., with segms. reflexed to the st., of a bright lemon-yellow, spotted purple-black; anthers reddish brown. Late July, Aug. Japan. El. 39. F.W. 1869:65. G. 15:319. Gn.W. 20:908.—A very beautiful lily, but is rather capricious and often difficult to establish in the open ground. The var. **màjus,** Wilson, is of larger growth, often 5 ft. high, with lvs. 6–7 in. long.

37. **Maximòwiczii,** Regel (*L. pseùdo-tigrìnum,* Carr. *L. tigrìnum* var. *jocúndum,* Hort. *L. tigrìnum* var. *Líshmannii,* Moore). Bulb similar to that of *L. Leichtlinii:* st. 3–5 ft. high, green, slightly tinged and spotted purple, smooth or slightly pubescent: lvs. 100 or more, horizontal, 2–4 in. long, ¼–⅓in. wide: fls. 1–12, 3–4 in. diam., soft salmon-red spotted purplish black; segms. reflexed to the st. and papillose at the base; anthers red. Aug., early Sept. China, Japan and the Liu Kiu Isls. El. 40. B.M. 5673. F.S. 17:1736 (yellow variety). I.H. 15:540. R.H. 1867:410. Gn. 21:236 (yellow variety); 42, p. 193 (not typical). Gn. W. 25:649 (as *L. Leichtlinii* var. *Maximowiczii*).—Often called the red *L. Leichtlinii* and thought by some authorities to be a natural hybrid between that species and *L. tigrinum.* Unlike the former, the st. rises erect from the bulb and no bulbils are borne in the lf.-axils, as in *L. tigrinum.*

38. **callòsum,** Sieb. Bulb globular, 1–2 in. diam., white or pale yellow: st. smooth, 1–2 ft. high: lvs. 30–40, erect, 2–4 in. long, 1/12–⅙in. wide: fls. 1–8, 1½–2 in. diam., bright scarlet, usually slightly dotted purple-black; anthers red or scarlet: at the junction of each fl.-bearing st. or pedicel with the main st., there are 2 thick, blunt, callous bracts, whence the specific name. June, early July. Japan and the Loo Choo Isls.—Very rare and only desirable for specialists. *L. stenophýllum,* Baker, from E. Siberia, resembles *L. callosum,* but the bulb is more oval, the st. stouter and taller, the lvs. larger and broader and the perianth-segms. narrower.

39. **tenuifòlium,** Fisch. (*L. linifòlium,* Hort. *L. pùmilum,* DC. *L. puníceum,* Sieb. & De Vr.). Coral Lily. Fern-leaved Lily. Tom Thumb Lily. Tiny Lily. Bulb oblong, 1–2 in. long, ½–1 in. wide, white or pale yellow sometimes tinged pink; scales few, large, closely clasped together: st. 1–2 ft. high, slender, smooth, bare of lvs. for 2–3 in. above the surface: lvs. 40–60, erect or semi-horizontal, 1–2 in. long, 1/12–⅙in. wide: fls. 1–15, 1½–2 in. diam., with waxy segms. reflexed to the st. and of a brilliant scarlet, rarely slightly dotted purple and lighter at the base; anthers scarlet or red. June, early July. S. Siberia and N. China. El. 42. B.M. 3140. L.B.C. 4:358. G.M. 45:443. J.H. III. 62:572.—A handsome, graceful species and the brightest in color of all. Although easily grown it is not very long-lived, as a rule, and must be frequently renewed. Good for rock-gardens and pots. The var. Golden Gleam, Hort., is a taller grower, often 3 ft. high and the fls. are bright, pure golden yellow; it is said to be a hybrid between *L. Martagon* var. *album* and *L. tenuifolium,* but resembles the latter in growth,

and the two form a splendid contrast when planted together.

40. **sutchuenénse**, Franch. Bulb globular, 1–2 in. diam., with white, closely imbricated scales: st. 3–5 ft. high, the underground part running along horizontally before coming to the surface: lvs. thickly scattered, linear, deep green: fls. 1–20, pendulous, with reflexed orange-red segms. spotted purplish black; anthers red. June, July. Sutchuen, W. China. B.M. 7715. G.C. III. 38:90; 54:115. G.M. 48:501. G.W. 11, p. 114. J.H. III. 51:130. G. 31:243. A.F. 29:154. F.S.R. 3, p. 329.—Said to be allied to *L. tenuifolium.*

41. **testàceum**, Lindl. (*L. excélsum*, Hort. *L. Isabellìnum*, Kunze). Nankeen Lily. Bulb similar to that of *L. candidum:* st. 3–6 ft. high, green, tinged purple-brown, slightly pubescent: lvs. 60–100, lower ones horizontal or nearly so, 3–4 in. long, ¼–⅓in. wide, upper ones smaller and more erect: fls. 1–12, 2–3 in. diam., deliciously fragrant, of a pale, delicate creamy buff or nankeen-yellow, often flushed pink and rarely slightly dotted red, segms. reflexed to the st. and slightly papillose at the base; anthers red. Late June, July. Unknown in a wild state; probably a garden hybrid between *L. candidum* and *L. chalcedonicum.* El. 44. B.R. 29:11 (too highly colored). P.M. 10:221. Gn. 60, pp. 46, 153; 62, p. 322; 66, p. 399; 71, p. 519. G.C. III. 55:33. G. 28:713. Gn.W. 16:27; 21:667.—One of the most beautiful and graceful of all lilies, hardy, robust, permanent and highly recommended for both pots and open ground.

SUBGENUS IV. PSEUDO-MARTAGON.

A. *Perianth widely expanded, pendulous*. . 42. **canadense**

AA. *Perianth narrow.*

  B. *Fls. pendulous or nearly so.*

    C. *Color of fls. reddish purple*. . . . . . . 43. **Bolanderi**

    CC. *Color of fls. orange-red.*

      D. *Californian species*. . . . . 44. **maritimum**

      DD. *Eastern species*. . . . . 45. **Grayi**

  BB. *Fls. horizontal or nearly erect*. . . . . . 46. **parvum**

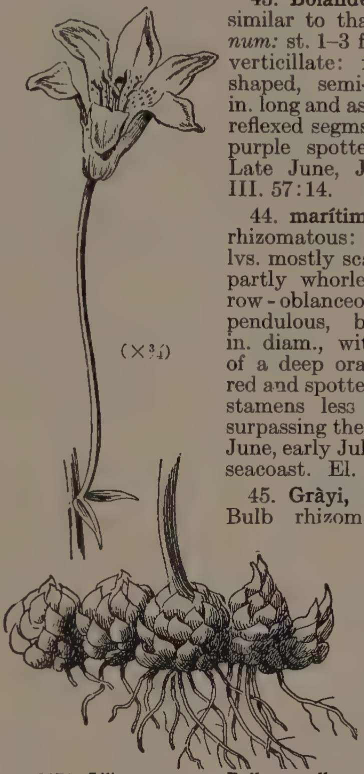
42. **canadénse**, Linn. (*L. penduliflòrum*, DC. *L. péndulum*, Spaeth). Meadow Lily. Wild Yellow Lily. Fig. 2169. Bulb rhizomatous, similar to that of *L. superbum*, but usually smaller: st. 2–5 ft. high, smooth, slender, bare of lvs. for 6–8 in. above the surface: lvs. horizontal, 2–4 in. long, ⅓–¾in. wide, usually in 4–8 whorls of 4–10 lvs. each, with a few scattered ones above and below: fls. 1–10, 2–3 in. long and as wide, bright orange-yellow spotted purplish brown; anthers red. Late June to early Aug. New Bruns. to Ont., Minn., Mo., Ga. and Ala. El. 27. B.M. 858 (poor). Gn. 29:426; 34, p. 182. J.H. III. 42:131. Gn. M. 9:236. A.G. 8:249.—Our commonest native species; although not so handsome or showy as *L. superbum* which it resembles in habit of growth, or *L. philadelphicum*, it is more graceful than either and is well worthy of cult. Var. **flàvum**, Kunth (var. *lùteum*, Hort.), produces lemon-yellow fls. spotted purplish brown. B.M. 800. Var. **coccíneum**, Kunth (var. *rùbrum*, Hort.), produces larger fls. of a bright orange-red, spotted purplish brown and heavily tinged deeper red on the outside.

2170. Lilium Grayi. Flowers usually more pendulous. (×½)

43. **Bolánderi**, Wats. Bulb similar to that of *L. columbianum:* st. 1–3 ft. high: lvs. mostly verticillate: fls. 1–3, thimble-shaped, semi-pendulous, 1½–2 in. long and as wide, with slightly reflexed segms. of a deep reddish purple spotted purplish black. Late June, July. Calif. G.C. III. 57:14.

44. **marítimum**, Kellogg. Bulb rhizomatous: st. 2–5 ft. high: lvs. mostly scattered, sometimes partly whorled, linear to narrow-oblanceolate: fls. 1–12, pendulous, bell-shaped, 1½–2 in. diam., with reflexed segms. of a deep orange-yellow, tipped red and spotted brownish purple; stamens less than 1 in. long, surpassing the style; anthers red. June, early July. Calif., along the seacoast. El. 12.

45. **Gràyi**, Wats. Fig. 2170. Bulb rhizomatous, similar to that of *L. canadense*, but smaller: st. 2–4 ft. high, slender, smooth, bare of lvs. near the base: lvs. horizontal or nearly so, 1½–3 in. long, ½–¾ in. wide, usually in 4–8 whorls of 3–8 lvs. each, with a few scattered ones above and below: fls. frequently solitary, sometimes 2–6 together, 1½–2 in. long, nearly as wide, orange-yellow inside, tipped and tinged dull red and thickly spotted deep purplish brown, outside deep reddish brown; anthers red. Late June, July. Va. and N.C. B.M. 7234, F.S.R. 1:262. G. 29:475. G.C. III. 30:69. G.M. 49:142. G.F. 1:19 (adapted in Fig. 2170).—Not a showy species, but very graceful and of easy cult. Excellent for both pots and open ground.



2171. Lilium parvum. Bulbs usually more clustered.

46. **párvum**, Kellogg. Fig. 2171. Bulb a scaly rhizome, 2–3 in. long, covered with small, thick, white scales, often jointed 1–3 times: st. 2–5 ft. high, slender, smooth: lvs. horizontal, 1–3 in. long, ¼–¾in. wide, the upper and lower ones scattered with a few whorls between: fls. 1–15, 1½–2 in. long and as wide; ends of segms. bright orange-scarlet, while the base is bright yellow, spotted purplish brown; anthers red. June, early July. Sierra Nevada Mts. of Calif. El. 30. B.M. 6146. F.S. 21:2192. J.H. III. 31:113.—A graceful pretty species of easy cult., but not showy. Var. **lùteum**, Hort., produces clear bright yellow fls. spotted purplish brown and with orange anthers.

SUBGENUS V. ISOLIRION.

A. *Lvs. mostly whorled.*

  B. *Japanese species* . . . . 47. **medeoloides**

  BB. *American species* . . . . 48. **philadelphicum**

AA. *Lvs. scattered.*

  B. *Style longer than ovary.*

    CC. *European species.*

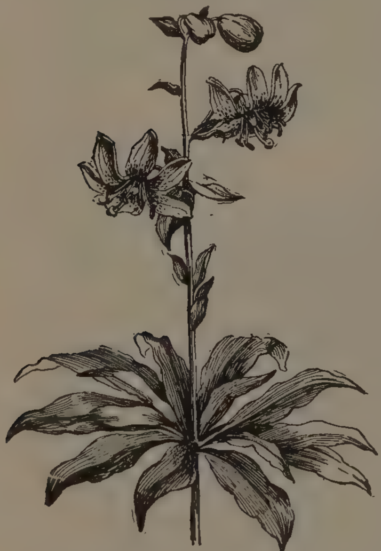
      D. *St. bulblet-bearing*. . . . . 50. **bulbiferum**

      DD. *St. not bulbiferous*. . . . . 51. **croceum**

CCC. *Asiatic species.*
D. *Early-flowering.*
E. *St. not over 2 ft. high*.......52. **elegans**
EE. *St. 2 ft. or more high*........53. **dauricum**
DD. *Late-flowering.*
E. *St. not over 2 ft. high*.......54. **Wallacei**
EE. *St. 2 ft. or more high*........55. **Batemanniæ**
BB. *Style shorter than ovary or of the same length*....................56. **concolor**

47. **medeoloìdes,** Gray (*L. maculàtum,* Thunb.). Wheel Lily. Spotted Lily. Bulb very similar to that of *L. avenaceum:* st. 1–2 ft. high, smooth or slightly furrowed, lower part bare of lvs.: lvs. 4–6 in. long, ¾–1½ in. wide, usually in 1–2 whorls of 7–14 lvs. each near middle of st. with a few scattered ones above: fls. 1–6, smooth inside, bright orange-red slightly dotted purple; anthers red. Late June, July. Korea and N. Japan.—Very rare, and recommended only for specialists.

48. **philadélphicum,** Linn. Wild Red Lily. Wood Lily. Fig. 2173. Bulb globular or nearly so, 1–1½ in. diam., white or pale yellow; scales small and thick, sometimes jointed: st. 1–3 ft. high, slender, smooth, lower part bare of lvs.: lvs. horizontal, 2–4 in. long, ¼–½ in. wide, usually in whorls of 3–8 lvs. each, with a few scattered ones above: fls. 1–5, 3–4 in. diam., smooth inside, bright orange-red tinged yellow in center and spotted deep purple; anthers red. Late June, July. Maine to Minn., Mo. and N. C., also Canada, as far west as Sask. El. 17. B. R. 594. L.B.C. 10: 976. B.M. 872 (as *L. pennsylvanicum*); 519. C. L. A. 17: 544.—Our most beautiful native lily, but indifferent to cult., the best specimens usually being found in a wild state. Var. **andìnum,** Nutt., the Western Red Lily, is a stronger grower, with larger, more richly colored fls. and mostly scattered lvs. Ohio to Mont., Col. and Ark. Var. **wausharaìcum,** Leicht., originally found in Waushara Co., Wis., is very similar, if not identical. So also are *L. lanceolàtum,* Fitzp., *L. montànum,* Nelson, and *L. umbellàtum,* Pursh.

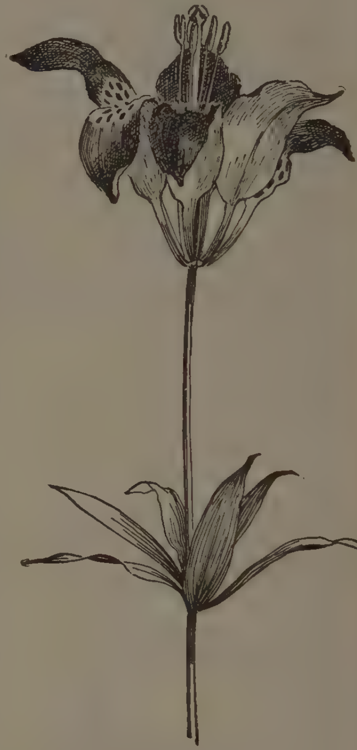


2172. Lilium Hansonii. No. 29. (×⅓)

49. **Catésbæi,** Walt. Southern Red Lily. Bulb oblong, 1–2 in. long, ¾–1 in. wide, composed of a few long, narrow, white scales: st. 1–2 ft. high, slender, smooth: lvs. semi-erect or nearly horizontal, 1–3 in. long, ⅓–½in. wide: fls. 1–3, 3–4 in. diam., smooth inside, of the same color as those of *L. philadelphicum;* anthers red. Late June, July. N. C. to Fla. and Ala. El. 25. B.M. 259. L.B.C. 9:807. R.H. 1868:431 (poor). —Rather tender and capricious, and in the North best grown in pots.

50. **bulbíferum,** Linn. Bulb globular or slightly spherical, 2–4 in. diam., white or pale yellow, often tinged red or purple: st. 2–4 ft. high, furrowed, green, tinged and spotted purplish brown, upper part covered with white down and producing bulbils in the lf.-axils: lvs. 50–75, horizontal or semi-erect, 3–4 in. long, ¼–½ in. wide: fls. 1–4, 3–4 in. diam., bright orange-red spotted deep purplish black and tinged or blotched yellow in center; anthers red. June, early July. Cent. Eu. and S. E. Scandinavia. El. 23. B.M. 36.—A hardy, long-lived species of the easiest cult., but not often seen. Var. **latifòlium,** Hort., is a larger, stronger grower with wider lvs. Var. **hùmile,** Hort., is of smaller growth, with narrower lvs.

51. **cròceum,** Chaix (*L. aùreum,* Parkin. *L. aurantìacum,* Hort.). Bulb similar to that of *L. bulbiferum:* st. stout, 3–6 ft. high, furrowed or striated, deep green, lower part spotted deep purple, upper part and buds covered with white down: lvs. 50–100, horizontal or semi-erect, 2–4 in. long, ¼–⅓in. wide: fls. 1–20, 3–4 in. diam., bright orange-yellow spotted purplish black in center and sometimes tinged red; anthers red. Late June, July. Alps Mts. of Switzerland, France and N. Italy. L.B.C 8:784 (poor). Gn. 71, p. 43. —A handsome, showy lily, hardy, vigorous, long-lived, of the easiest cult. and highly recommended. Var. **Chàixii,** Hort., is of much smaller growth, only 1–1½ ft. high, with 1–3 fls. and comes into bloom earlier. El. 22.



2173. Lilium philadelphicum. (×⅓)

52. **élegans,** Thunb. (*L. lancifòlium,* Thunb. *L. Thunbergiànum,* Roezl. & Schult.). Fig. 2174. Bulb spherical or nearly globular, 1–2 in. diam., white or pale yellow, often tinged red or purple: st. 1–1½ ft. high, smooth or slightly furrowed, green, upper part slightly pubescent: lvs. 20–40, horizontal or semi-erect, 2–4 in. long, ¼–½in. wide: fls. 1–4, 4–6 in. diam., orange-red, slightly spotted purplish black; anthers red. June, early July. Japan. El. 19, 20. Gn. 38:440; 47, p. 415; 62, p. 359; 67, p. 204. F.1868:121. F.S. 16:1627. I.H. 12:459 (as *L. formosum*). G.W. 3, p. 355. H.U. 4, p. 201.—There are innumerable varieties and the origin of some of them is difficult to trace, but they probably have some blood of related species, such as *L. croceum, L. bulbiferum* and *L. dauricum,* in their make-up. Var. **alutàceum,** Baker & Dyer (var. *aùreum nìgro-maculàtum,* Hort.; var. *Kìkak,* Hort.), grows only 6–9 in. high, blooms earlier and produces solitary, pale apricot-colored fls. spotted purple-black. F.S. 22:2319. A form of this, var. **grandiflòrum,** is a larger, stronger grower. Var. **armeniàcum,** Baker & Dyer (var. *venústum,* Kunth), blooms later than the type, producing 1–2 bright orange-scarlet, unspotted fls., smooth inside: the lvs. are peculiarly twisted. Var. **atrosanguíneum,** Baker & Dyer (var. *corúscans,* Hort.), produces solitary deep blood-red fls., spotted purple-black. Var. **Alice Wilson,** Hort., produces pure lemon-yellow spotted fls. Var. **aurantìacum,** Hort., produces unspotted salmon fls. P.M. 6:127. Var. **bícolor,** Hort. (var. *pìctum,* Hort.), has narrower lvs. than those of the type and broader perianth-segms.: fls. 2–4, yellow,

edged and tipped bright red, spotted purple-black. Var. **brevifòlium,** Baker & Dyer, has shorter lvs. than the type and blooms earlier, producing solitary fls. of a pale orange-red, spotted purple-black and flaked yellow at base of segms. Var. **citrìnum,** Wilson, is a stronger grower than the type, 2–2½ ft. high, and blooms later, producing 2 or 3 unspotted citron-yellow fls. Var. **fúlgens,** Morr., has narrower lvs. than the type and produces 4–6 deep orange-red fls., very slightly, or not at all, spotted. A semi-double form of this, of little value, is known as var. **semi-plènum,** Hort. (var. *staminòsum,* Hort.). G.M. 46:597. Var. **álternans,** Sieb., is similar to var. *fulgens,* but the fls. are suffused or flaked yellow. Var. **hæmatóchroum,** Lem. (var. *Hórsmannii,* Hort.), produces deep blood-red fls. thickly spotted purple-black. Var. **Màwi,** Hort., produces orange fls. flaked crimson and spotted purple-black. Var. **marmoràtum,** Hort., blooms earlier than the type, producing 2–4 rich crimson fls. flaked and tipped orange-yellow and slightly spotted. Var. **marmoràtum aùreum,** Hort. (var. *robústum,* Hort.), produces orange-yellow fls., edged, flaked and tipped crimson and more thickly spotted. A.F. 35:105. Var. **Orange Queen,** Hort., produces 1–3 bright orange fls. which are larger and with broader segms. than those of the type. Var. **Prince of Orange,** Hort., is dwarfer than the type, blooms earlier and produces soft buff fls., spotted purple-black. Var. **sanguíneum,** Lindl., also blooms earlier, producing 1–2 blood-red fls. slightly tinged orange and spotted purple-black. Var. **biligulàtum,** Hort. (var. *lateritium,* Hort.), is similar, but with deeper chestnut-red, spotted fls. Var. **spléndens,** Hort., is a larger, stronger grower than the type, often 2½ ft. high, with broader, paler lvs. and blooms earlier producing rich apricot-yellow, spotted fls. Var. **Van Hoùttei,** Hort., produces deep crimson-scarlet fls. with a yellow blotch near the center of each segm. Var. **Wílsonii,** Hort. (var. *pardìnum,* Morr.), is a stronger grower than the type, 2–3 ft. high, with shorter, curved lvs. and blooms later, producing apricot-colored fls., spotted deep purple and with a yellow band through the center of each segm.—All the above varieties, as well as the type, are of the easiest cult. in almost any soil or location and are highly recommended for general planting. They are excellent for rock-gardens, pots or naturalizing.

2174. Lilium elegans. (×⅙). No. 52

53. **daùricum,** Ker-Gawl. (*L. spectábile,* Fisch. & Mey. *L. umbellàtum,* Hort.). Candlestick Lily. Bulb similar to that of *L. elegans* but usually larger: st. 2–3 ft. high, smooth or slightly furrowed, green, sometimes tinged purple or brown; upper part slightly pubescent: lvs. 20–50, horizontal or nearly so, 3–5 in. long, ¼–⅓in. wide: fls. 1–5, 3–5 in. diam., orange-red slightly spotted purplish black and tinged yellow in center; anthers red. June, early July. S. E. Siberia.—Of the same easy cult. as *L. elegans,* succeeding almost anywhere. Var. **atrosanguíneum,** Hort., is of stronger growth with deeper blood-red fls. tinged or blotched yellow in the center and spotted purple-black. Vars. **incomparábile,** Hort., **grandiflòrum,** Hort., **multiflòrum,** Hort., are all similar, if not identical. Var. **Dìadem,** Hort., produces bright crimson fls. with a yellow band through each segm. Var. **eréctum,** Hort., produces yellow fls. tipped orange-red, slightly, or not at all spotted. Var. **bícolor,** Hort., is similar. Var. **lùteum,** Hort., produces bright yellow fls. thickly spotted. G. 36:431. Gn. 79, p. 39. G.C. III. 51, suppl. June 1. Var. **punctàtum,** Hort. (var. *rùbens,* Hort.), produces orange-yellow, spotted fls. Var. **immaculàtum,** Hort. (var. *Vúlcan,* Hort.), is similar but the fls. are unspotted. Var. **Sáppho,** Hort., is a dwarfer grower than the type, with orange-yellow fls. tipped and splashed red and spotted purple-black. The following four varieties appear to be related to *L. croceum* and *L. elegans,* as they resemble them in certain respects. Var. **aurantìacum,** Hort., with orange-yellow fls.; var. **Cloth of Gold,**. Hort., also with bright orange-yellow fls.; var. **Sensation,** Hort., orange-red fls.; and var. **Tóttenhamii,** Hort., with bright pure yellow fls.

54. **Wállacei,** Wallace (*L. élegans* var. *Wállacei,* Hort.). Bulb cespitose, globular or nearly so, 1–1½ in. diam., composed of a few broad, white scales, often tinged pink or purple: st. 1–2 ft. high, smooth, green, tinged purplish brown: lvs. 50–75, horizontal or semi-erect, 1½–3 in. long, ¼–⅓in. wide: fls. 1–10, 4–5 in. diam., smooth inside, pale orange-red or apricot, spotted purplish black; anthers red; segms. only slightly, or not at all, clawed at the base. Late July, Aug. Japan. Gn. W. 21:739.—Thought by some authorities to be a hybrid between *L. tigrinum* or *L. Maximowiczii* and *L. concolor.* Easily grown and deserving of more general cult., both for pots and open ground.

55. **Bàtemanniæ,** Wallace (*L. élegans* var. *Bàtemanniæ,* Hort.). Bulb, quite similar to that of *L. tigrinum:* st. 2–4 ft. high, smooth, green, lower part shaded brown: lvs. 100 or more, horizontal, 2–5 in. long, ¼–¾ in. wide, upper ones slightly recurved: fls. 1–12, 3–5 in. diam., pale orange-red or apricot, sometimes tinged pink, unspotted; anthers red; segms. smooth or nearly so inside, only slightly, or not at all, clawed at the base. Late July, Aug. Japan. G. 28:455.—Perhaps a hybrid between *L. Leichtlinii,* or *L. Maximowiczii* and some variety of *L. elegans.* It is strong, hardy, easily grown and highly recommended for general cult.

56. **cóncolor,** Salisb. Star Lily. Bulb cespitose, similar to that of *L. Wallacei:* st. 1–1½ ft. high, green, tinged purple, slightly pubescent: lvs. 20–30, erect or semi-horizontal, 1½–3 in. long, 1/12–⅛in. wide: fls. 1–4, 2–3 in. diam., bright crimson-scarlet, slightly, or not at all, dotted purple-black; anthers red. Late June, July. Japan. El. 18. B.M. 1165. F.W. 1873: 289.—A graceful, handsome lily of easy cult., excellent for both pots and open ground. Var. **Parthenèion,** Sieb. & De Vr., is very similar, if not identical. Var. **Corìdion,** Sieb. & De Vr., produces slightly larger fls. of a rich yellow, flaked brown.—**L. pulchéllum,** Fisch. & Mey. (*L. Buschiànum,* Lodd.), is allied to *L. concolor,* but differs from it in the bulb being solitary and more oval, the lvs. slightly wider and of a deeper green, the fls. appearing earlier, slightly smaller and more thickly spotted. S. E. Siberia and Manchuria. Var. **lùteum,** Hort., from Mongolia, produces rich yellow, spotted fls.—**L. sínicum,** Lindl., resembles *L. pulchellum,* but grows 2–3 ft. high and produces 4–6 larger fls. China and S. Siberia. B.M. 6005. L.B.C. 17:1628 (as *L. Buschianum*).

SUBGENUS VI. CARDIOCRINUM.

A. *Fls. horizontal or slightly pendulous*. . .57. **giganteum**
AA. *Fls. erect or nearly so*. . . . . .58. **cordifolium**

57. **gigantèum,** Wall. Bulb oval, 6–8 in. long, 4–6 in. wide, deep green tinged brown; scales few, very broad and thick, closely clasped together and blunt at the ends: st. 4–12 ft. high, stout, smooth, 1½–3 in. diam. at base: lvs. 12–20, scattered, deep green, lower ones horizontal or nearly so, 12–18 in. long, nearly as

wide, upper ones smaller and more erect: fls. in racemes of 6–12, 5–6 in. long, nearly as wide, deliciously fragrant, with waxy segms., which, when first opening, are citron-yellow inside, soon changing to pure white tinged purple near the base and with purple midribs, outside often shaded green; anthers yellow. July, early Aug. Himalaya Mts. from Kumaon and Gurwhal to Khasia and Sikkim. El. 2. B.M. 4673. F. 1874, p. 79. R.H. 1861, p. 310. I.H. p. 11. G.C. III. 8:47; 16:754; 30:51; 38:296. Gn. 8:504; 34, p. 269; 52, p. 226; 60, p. 47; 69, p. 199; 71, p. 439; 74, p. 142; 77, p. 35. J.H. III. 46:336; 53:347; 65:113. G.M. 48:787. G.W. 5, p. 67; 7, p. 412. J.F. 4:409–11. A.F. 22:5. G.F. 6:376.—A beautiful, stately lily, rarely cult. in this country, but hardy as far north as Boston, and easily grown in light, well-drained soil; should be heavily mulched during the winter; also excellent for greenhouse benches or large tubs. After once flowering, the old bulb decays and disappears, leaving several offsets. Var. **yunnanénse,** Hort., from China, is said to produce larger, better-colored fls.

58. **cordifòlium,** Thunb. Bulb similar to that of *L. giganteum*, but smaller: st. 3–4 ft. high, stout, smooth, bare of lvs. for a foot or more above the surface, then a whorl of 6–8 lvs. appears, with a few scattered ones above; they are pendulous, 12–18 in. long, nearly as wide, deep green, lower ones tinged deep red: fls. in racemes of 4–10, 4–6 in. long, nearly as wide, fragrant, of the same color as those of *L. giganteum*. July, early Aug. Japan and the Kurile Isls. El 1. G.C. III. 8:41. B.M. 6337.—Very rare and not so easily grown as *L. giganteum*, to which it is inferior in every respect; only suitable for collectors or specialists.

SUBGENUS VII. NOTHOLIRION.

59. **ròseum,** Wall. (*L. Thomsoniànum*, Lindl. *Fritillària Thomsoniàna*, Royle). A peculiar plant, suggesting Hosta, Anthericum, Ornithogalum, and similar things: st. erect, about 1½ ft.: lvs. like a Hemerocallis, linear-acuminate and grassy, mostly crowded at the base of the st.: fls. as many as two dozen, pale mauve, about 1½ in. long, and nearly as broad at the mouth, bell-shaped, the 6 segms. free to the base; anthers deep purple, oblong; stigma 3-lobed. W. China to N. India (Himalaya). B.M. 4725. B.R. 31:1. J.H. III. 64:279. Gn. 76, p. 158; 67, p. 302 (var. *multiflorum*, Leicht.).—Little cult. abroad; may be desirable in milder parts of this country.

L. albánicum, Griseb. Very similar to L. Jankæ. Albania.—*L. Alexándræ*, Baker (L. japonicum var. Alexandræ, Hort.). St. 2–3 ft. high: lvs. scattered, 5–6 in. long, ½–¾in. wide: fls. trumpet-shaped, usually solitary, semi-erect, 5–6 in. long, nearly as wide, delicately fragrant, with waxy, pure white segms., shaded green at the base. Late June, July. Liu Kiu Isls. Possibly a hybrid between L. auratum and L. longiflorum.—*L. Bàkeri*, Purdy (L. Purdyi, Waugh). Bulb similar to that of L. columbianum: st. 2–5 ft. high: lvs. mostly verticillate: fls. 1–10, horizontal or semi-pendulous, slightly fragrant, with reflexed orange-red segms. spotted deep purple. Wash. and Brit. Col.—*L. Bakeriànum*=L. Lowi.—*L. Bérensii*, Hort. A garden hybrid between L. testaceum and L. chalcedonicum: st. 3–4 ft. high: fls. fragrant, similar to those of L. testaceum in size and shape, but brighter, and richer in color. Aug., early Sept.—*L. Bióndii*, Hort. Resembles L. Maximowiczii: st. 3–4 ft. high: lvs. scattered, linear: fls. several, pendulous, 2½ in. across, with reflexed segms., orange-red spotted deep purple-black with reddish brown anthers. G.M. 57:693.—*L. claptonénse*, Hort.=L. primulinum.—*L. Dàvidii*, Duch. Allied to L. concolor; st. 2–3 ft. high, with narrow, scattered lvs.; fls. erect, solitary, star-shaped, orange, spotted purple. Thibet. El. 24.—*L. Delavàyi*, Franch. Fls. rosy crimson; belongs in subgenus Archelirion. China.—*L. Dòei*, Hort. A garden hybrid, resembling L. longiflorum. J.H. III. 51:27, desc.—*L. Duchártrei*, Franch. St. about 3 ft. high, smooth: lvs. lanceolate, acuminate, 2½ in. long, ½in. wide: fls. 1–7, pendulous, 3 in. diam., white, tinged rose outside, finely spotted inside. W. and S.W. China. B.M. 8072.—*L. Fárgesii*, Franch. A Martagon with small yellow fls. China.—*L. Fárquhari*, Hort.=L. Sargentiæ. F. E. 33:492.—*L. formòsum*, Franch. Fls. erect, white, similar to those of L. elegans. China.—*L. Gléhnii*, F. Schmidt. Differs only slightly from L. cordifolium. Japan.—*L. Heldreìchii*, Baker. Intermediate between L. carniolicum and L. chalcedonicum: st. 2–3 ft. high, with narrow, scattered lvs. and 1–4 bright orange-red fls. tinged yellow outside. Late June, July. Greece.—*L. kewénse*, Hort. A garden hybrid between L. Henryi and L. Browni var. Chloraster; resembles a small L. auratum in habit of growth and form of fls., but the lvs are similar to those of L. Henryi; fls. rich cream-color, fading to nearly white and with a deep creamy-yellow band through the center of each segm. July, Aug. G.C. III. 29:116. Gn. 58, p. 99.—*L. lankongénse*, Franch. Fls. purple, spotted black. Belongs in subgenus Martagon. Yunnan, China.—*L. lophóphorum*, Franch. A Martagon about 1 ft. high, with canary-yellow fls. Western China.—*L. Lòwi*, Baker (L. Bakerianum, Coll. & Hemsl.). St. 2–3 ft. high: lvs. scattered, narrow, erect: fls. 1–3, pendulous, bell-shaped, 3–4 in. long, nearly as wide, with slightly recurved ivory-white segms. spotted or blotched purple near the base inside and tinged green outside. Yunnan and N. Burma. J. H. III. 43:55. G. 27:645. G.C. III. 14:121; 30:45; 38:75. Gn. 45:278. B. M. 7232.—*L. Màsseyi*, Hyams. A southern form of L. philadelphicum, differing but slightly. N. C.—*L. Miqueliànum*, Makino. Said to be an improved form of L. medeoloides. Japan.—*L. miràbile*, Franch. Similar to L. cordifolium. China.—*L. occidentàle*, Purdy. Resembles L. maritimum, but the segms. of the fls. are more reflexed: bulb rhizomatous: st. 2–4 ft. high: lvs. usually verticillate, lower ones sometimes scattered: fls. 1–15, orange-yellow, tipped red, spotted purple. Calif.—*L. ochráceum*, Franch. A yellow-flowered Martagon resembling L. monadelphum. China.—*L. oxypétalum*, Baker. 1–1½ ft. tall: lvs. 20–30, scattered, lanceolate-linear: fl. wide funnel-shaped or nearly rotate, purplish, tinged with green beneath, somewhat dotted inside. W. Himalayas. El. 5.—*L. papillíferum*, Franch. A dwarf L. Maximowiczii, with orange-red fls. China.—*L. Párkmannii*, T. Moore. A hybrid between L. auratum and L. speciosum: st. slender, 2–4 ft. high: lvs. scattered, alternate: fls. 8–12 in. diam. of the same shape as those of L. auratum, but colored like those of L. speciosum. G.C. III. 30:52.—*L. pónticum*, Koch. Resembles L. monadelphum, but is smaller, seldom over 2 ft. high. Asia Minor.—*L. primúlinum*, Baker (L. claptonense, Hort.). Fls. pure primrose-yellow, trumpet-shaped, intermediate in form between those of L. neilgherrense and L. nepalense. N. Burma. B.M. 7227.—*L. Púrdyi*=L. Bakeri.—*L. Rósthernii*, Diels. Belongs in subgenus Martagon. China.—*L. taliénse*, Franch. A tall-growing Martagon with white fls. China.—*L. Thàyeræ*, Wilson. Bulb 2–2½ in. diam., ivory-white: st. 4–4½ ft. high, clothed with long, linear lvs. and usually bearing 16 or 17 fls. W. China. G.C. III. 54:116. Intro. as L. sutchuense.—*L. tubiflòrum*, Wight. Closely resembles L. neilgherrense, except the lvs. and perianth-segms. are narrower. Himalaya Mts.—*L. Wàrei*, Purdy. Said to be intermediate in character between L. pardalinum and L. Parryi: fls. fragrant, bright yellow, spotted deep purple. Calif.—*L. Willmottiæ*, Wilson (L. warleyense, Hort.). St. about 4 ft. high: lvs. numerous, spirally arranged, linear, 3–5 in. long: fls. 20 or more, pendulous, 3 in. diam., recurved, orange-red, spotted reddish brown. China. G.M. 55:513.—*L. Yóshidaii*, Leicht. Fls. fragrant, resembling those of L. Brownii. Philippine Isls. Gn. 68, p. 238.—*L. yunnanénse*, Franch. St. 1–3 ft. high: fls. 1–3, small, pendulous, pink or nearly white. Yunnan, China.

JOHN H. TILTON.

LILY, in the narrowest sense, is restricted to the genus Lilium, but the popular names given below also include plants outside the family Liliaceæ. Many of them belong to the Amaryllis family. **African Blue L.,** *Agapanthus umbellatus*. **African Corn L.,** *Ixia*. **Amazon L.,** *Eucharis grandiflora*. **American Turk's-Cap L.,** *Lilium superbum*. **Atamasco L.,** *Zephyranthes Atamasco*. **Barbados L.,** *Hippeastrum equestre*. **Belladonna L.,** *Amaryllis Belladonna*. **Bengal L.,** *Crinum*. **Bermuda L.,** *Lilium Harrisii*. **Black L.,** *Fritillaria camtshatcensis*. **Blackberry L.,** *Belamcanda chinensis*. **Bourbon L.,** *Lilium candidum*. **Brisbane L.,** *Eurycles sylvestris*. **Calla L.,** *Zantedeschia æthiopica*. **Cape L.,** *Crinum longifolium*. **Checkered L.,** *Fritillaria meleagris*. **Climbing L.,** *Gloriosa* and *Littonia*. **Common White L.,** *Lilium candidum*. **Day L.,** the blue and white ones are *Hostas;* the yellow and orange ones *Hemerocallis*. **Easter L.,** *Lilium Harrisii*. **Fairy L.,** *Zephyranthes rosea*. **Fayal L.,** *Ornithogalum arabicum*. **Golden-banded L.,** *Lilium auratum*. **Golden-rayed L.,** *Lilium auratum*. **Guernsey L.,** *Nerine sarniensis*. **Jacobean L.,** *Sprekelia formosissima*. **Kaffir L.,** *Schizostylis coccinea*. **Mariposa L.,** *Calochortus*. **Martagon L.,** *Lilium Martagon*. **Orange L.,** *Lilium croceum*. **Peruvian Swamp L.,** *Zephyranthes candida*. **Plantain L.,** *Hosta*. **Pond L.,** *Nuphar advena*. **Sacred L. of China,** *Narcissus Tazetta* var. *orientalis*. **Spider L., St. Bernard's L.,** *Anthericum Liliago*. **St. Bruno's L.** *Paradisea Liliastrum*. **St. James' L.,** *Sprekelia formosissima*. **St. Joseph's L.,** *Lilium candidum*. **Swamp L.,** *Lilium superbum*. **Sword L.,** *Gladiolus* in general. **Tiger L.,** *Lilium tigrinum*. **Turban L.,** *Lilium pomponium*. **Turk's-Cap L.,** *Lilium Martagon*. **Valley, L. of,** *Lily-of-the-valley*, p. 1879. **Water L.,** *Nymphæa*. **White L.,** *Lilium candidum*.

LILY-OF-THE-INCAS. *Alstrœmeria Pelegrina*. See, also, *Hymenocallis* (Ismene).

LILY-OF-THE-PALACE. *Hippeastrum aulicum*.

LILY-OF-THE-VALLEY (*Convallaria majalis*, which see) is forced in large quantities in the United States all the year round. It is native in Europe, where it grows wild in the woods. It is grown and cultivated in large quantities in Germany for the export trade and is shipped to every country, millions reaching the United States every season.

The growing of lily-of-the-valley roots for the trade is an important branch and is done in Germany by experts. No effort and pains are spared to develop the pips and to produce superior stock. They are planted out in the open in the fall after the fields have been well prepared, deeply plowed and heavily manured. Every fall a certain field is planted and another taken up. The average "valley" is grown three years in the open field; but the best product is derived from a two-year crop. The man who assorts his planting stock carefully and does his growing better, raises the finest "valley" in two years and gets the highest prices.

Lily-of-the-valley propagates itself through runners or suckers. In taking up a field in the fall, the pips are assorted. The best ones are used for shipping, the seconds and culls for home consumption and are forced during the winter season. The runners are carefully sorted out and are used for planting stock the next year. They are planted in furrows about 1 foot apart, covered with about 2 inches of soil. Later in the season they should receive a top-dressing of rotted horse- and cow-manure. However, when the soil is heavy, a top-dressing of clean river sand should be applied. The soil of the northern part of Germany is so fertile that an application of sand acts as an amendment. These top-dressings are repeated every winter.

During the summer, the fields should be kept free from weeds by hoeing and cultivating. In dry seasons motor watering-wagons are used for sprinkling. The utmost care should be given during the planting season to protect the roots and keep them fresh and free from mold. The many complaints in this country about poor forcing results are usually traced to careless handling at the time when the "valley" is harvested and the stock is spoiled in storage. Good "valley" pips should be strong and have plenty of fine fibrous roots. This is very essential for forcing purposes, as the "valley" does not root in the forcing-bed. If the roots are spoiled or affected through mold, the plants become worthless. The successful growing of lilies-of-the-valley in the open field requires large acreage. Different crops should be grown for three or four years before lilies-of-the-valley are again planted in the same field. It can not be grown successively on the same ground, as the stock deteriorates and becomes practically worthless.

The forcing of lilies-of-the-valley is done mostly by specialists in this country, where a steady supply is kept up every day in the year for the cut-flower trade. The importing is done in the fall, and on arrival in this country the pips are placed in cold storage. They keep best in a temperature of 28°. After resting two or three months, they are taken out as desired. Cold storage lilies-of-the-valley are much more satisfactory and should be grown at all times. They do not require any special management nor strong forcing, and do best at a temperature of 65°. It hardly pays a florist to force lilies-of-the-valley in small quantities unless it is for home trade for the holidays, for basket-work and in pots. The commercial success depends on many things, and much money has been lost in this country on lilies-of-the-valley. A successful grower must know where his stock comes from and when to grow the different kinds as grown abroad. For early forcing it is best to have "valley" grown on light soil, which forces easier; for late forcing and cold-storage purposes, "valley" grown on heavier soil is to be preferred.

The specialist devotes separate houses to the forcing of lilies-of-the-valley, where he is able to give the right atmosphere and ideal conditions for successful growing. Plant right in the benches, which are about 3½ feet wide. Fill benches about 5 inches deep with clean sand, not too fine. After planting, keep them well watered all the time. For the first ten to fourteen days keep them dark. For this purpose, the benches are boxed in and covered with boards or cloths. Give light gradually after the stalks are well up, and finally remove the shade entirely in order properly to develop the flowers, give them more substance, and color to the foliage. It requires about three weeks properly to force lilies-of-the-valley in a temperature of 68°. New "valley" requires a good bottom heat of about 70° to 75°. Cold storage "valley" does not need any bottom heat. After cutting, the flowers are placed in the cooler over night and put up in bunches of twenty-five for the market. They are mostly used for wedding and corsage bouquets, and also for baskets and table-decoration.

Lilies-of-the-valley are hardy and are easily grown in the garden. They require no special attention. They are adapted for planting around shrubbery, porches or shady places, where they come up every season and bring an abundance of beautiful flowers.

H. N. BRUNS.

LIMATÒDES (perhaps from the Greek for *meadow*, referring to the habitat of the plants). *Orchidàceæ.* Similar to Calanthe, but the spurred labellum is not adnate to the column but closely wrapped around it. In Phaius, and in Calanthe also, the leaves are not articulated to the stem and therefore wither on the plant instead of falling.—One species in India.

After resting season of limatodes is over, say from February to May, shake off the old potting material. If plants are large, divide them and pot them moderately tight. For the American climate, chop finely some good turfy loam well mixed with old rotten cow-manure and a little leaf-mold and sharp sand and place in a shaded house, temperature 70° to 90°. Do not water till roots are well out, and sparingly till leaves are well started. After that and during flower-sheath growth, they will enjoy profuse waterings and spraying; water with weak liquid at intervals of ten days or so, and every plant will be a marvel of beauty. (Wm. Mathews.)

ròsea, Lindl. (*Calánthe ròsea*, Benth.). Pseudobulbs 4–8 in. long, pyriform or fusiform, grooved: lvs. 8–18 in. long, elliptic-lanceolate, acuminate, plicate: scape from the base of the pseudobulb, 12–18 in. long, slender, bearing a many-fld. villous raceme; fls. large, rosy, 1½ in. across; sepals ovate-lanceolate; petals oblong, acute; lip 1½ in. long, with a large obovate-oblong midlobe; base yellow, edged with scarlet. Jan. Burma. B.M. 5312.—A hybrid of this species and *Calanthe vestita*, Lindl., is common in cult. under the name *Calanthe Veitchii*, Lindl., which see. It has been said that *L. rosea* bore fls. as large as those of *Calanthe Veitchii*, and more brilliant in color.

HEINRICH HASSELBRING.

LIME. The use of lime in agriculture antedates the Christian era. In modern times it has been an indispensable adjunct to potassic, phosphatic, and nitrogenous manures in restoring and maintaining the fertility of immense areas of soil derived from sandstone, granite, mica schist and certain shales and slates. Even limestone soils sometimes become so lacking in lime near the surface that they stand in great need of its application.

Without the use of lime, the wonderful transformation of Limousin in France, the sandy regions of Germany, and particularly the reclamation of the sour peat (Hoch-moor) soils of northern Germany would have been difficult or impossible. Its great value has also long been known in Scotland.

It is now recognized that lime is greatly lacking in parts of New England, New York, New Jersey, Pennsylvania, Maryland, Ohio, Illinois, Wisconsin, and in many of the southern and western states.

The chief function of lime is to correct the chemical reaction of acid soils.

The necessity of lime as a direct plant-food for the higher orders of plants has been indisputedly demonstrated and its physiological rôle is of the greatest significance.

Lime is of indirect service in various ways: (1) It aids in transforming the nitrogen of organic matter and ammonium salts into nitric acid, which, in combination with potash, soda, lime, and magnesia, furnishes most plants the major portion of their nitrogen. (2) It serves as an indirect food by transforming or setting free other soil ingredients which plants require. (3) It appears probable that liming favors symbiosis and the consequent assimilation of atmospheric nitrogen in the case of clovers, alfalfa and certain other legumes, while it may have an opposite effect upon others, among which may be mentioned serradella and certain lupines. (4) Lime attacks certain more or less inert combinations of potash and of phosphoric acid which exist in soils, thereby rendering their manurial constituents more readily assimilable. (5) Noxious iron compounds in soils are so acted upon by lime as to overcome their poisonous tendency. (6) The presence in soils of carbonate of lime and of silicates highly charged with lime prevents the formation of "sour" humus and toxic aluminum compounds, and hence injury to a large class of agricultural plants. (7) Liming makes clays more friable and sandy soils more compact, thus improving the texture of each. By the flocculation of the small particles of the former, water passes into them more readily and the danger of serious washing is thus diminished. (8) Soluble phosphates are less liable to be lost or changed into unassimilable forms in soils containing lime. (9) Lime lessens the danger of the destruction of nitrates, especially in soils which are in bad physical condition.

Large quantities of lime should not be employed on sandy soils in a single application, although there is less danger in using ground limestone than in the employment of either burned or slaked lime.

The repeated use of highly magnesian lime is fraught with possible danger, although if applied only occasionally in the place of ordinary lime the magnesia may sometimes prove highly beneficial.

The use of lime, whether in wood-ashes, burned lime, slaked lime, ground limestone, or combined with organic acids, increases the tendency to alkalinity of the soil, and hence makes it more favorable to the development of at least the common potato-scab, provided the fungus, which is the direct cause of the disease, is already in the soil or is introduced into it on the "seed" tubers.

The "root-rot" of tobacco, chlorosis of pineapples and the "dry spot" of oats may be promoted by excessive liming.

The disease which develops upon turnips and upon certain other plants, known as "club-foot," or "club-root" and "finger-and-toe," is lessened to a marked degree by large applications of lime. For this purpose burned and slaked lime are the most efficient forms to apply.

Slaked lime is usually applied to land, for ordinary purposes, at rates ranging from half a ton to two and a half tons to the acre, and at intervals of four to six years. Slaked lime usually contains 65 to 70 per cent of lime and magnesia; burned lime before slaking contains 90 to 98 per cent of lime and magnesia, whereas ground limestone and high grade marl contain from 48 to 52 per cent. The quantities of each of these forms to employ should be varied in accordance with their analysis, bearing in mind, however, that it is usually safer on light soils to make the applications of burned and slaked lime relatively smaller than those of ground limestone and marl. On all light, sandy, and gravelly loams which are likely to become dry, ground limestone or marl should always be used if possible, but for flocculating heavy clay soils, burned or slaked lime is usually more quickly effective.

Lime should be thoroughly worked into the surface soil after plowing. Slaked lime can be applied with much greater safety on sandy soils if it is first composted with vegetable matter. Its beneficial effects in connection with composting have long been known. If lime is mixed with layers of loam, weeds, muck, coarse stable manure and other vegetable and animal matter, it forms in a few months, if kept moist, an excellent material for the use of gardeners. If worked over a few times, at intervals, the fermentation is materially hastened. The introduction of a little common salt or of muriate of potash facilitates the process by virtue of the formation of carbonate of soda or carbonate of potash. In order to prevent the loss of ammonia, compost heaps should be kept covered with a layer of moist earth.

The influence of lime on plant growth is often astounding. Lettuce, spinach, beets, onions, muskmelons, asparagus, clovers, timothy, Kentucky bluegrass and certain poppies are almost failures on very acid soils until lime is applied. Watermelons, lupines, serradella, cranberries, rhododendrons, azaleas and other plants might be cited, some of which are known to be indifferent, injured, or even ruined by heavy applications of lime. Their natural home is on a sour soil. The Early Richmond and Black Tartarian cherries are both helped by liming. The Delaware grape seems to be helped by liming in a greater degree than the Concord. The Blackcap raspberry does not respond to liming on a very acid soil whereas the Cuthbert, a red variety, responds favorably to the treatment. The quince is more in need of lime on an acid soil than the apple, pear, or peach. The American linden and American elm are helped by lime on acid soils whereas the white birch may show utter indifference to it. The success of the beech on the limestone soils of Europe indicates its natural home. Chestnut trees are said not to thrive well on limestone soils, and the heavy liming of certain spruces and pines is often injurious, although it is reported from France that the light liming of certain soils which were presumably exceedingly acid has sometimes been found helpful. Goose-

2175. Acid lime.—Citrus aurantifolia. (×½) berries and currants are often helped by liming on soils where liming is detrimental, or of little or no aid, to the strawberry.

The state of Rhode Island owes its fame as the home of the Rhode Island bent to the fact that this grass can persist on very acid soils whereas many other grasses fail. On such soils there is but little likelihood that the common poppy will ever become a pernicious weed as it has in many of the wheat-fields of Europe. Such soils are, however, the natural home of the common sorrel. Among the cereals, Indian corn and rye are best adapted to acid soils, and these are followed in turn by oats, wheat, and barley.

The following table compiled from the results obtained at the Rhode Island Agricultural Experiment Station shows, numerically, some of the striking contrasts between different kinds of plants as concerns their response to liming.

Name of plant		Very acid soil		Moderately acid soil	
		Unlimed	Limed	Unlimed	Limed
Flowering plants.					
Galega officinalis, Goat's Rue	Height, inches	10.0	39.0	22.0	50.0
Salvia splendens, Scarlet Sage	Height, inches	6.0	6.0	6.0	6.0
Silene orientalis, Catchfly	Height, inches	30.0	25.0	30.0	24.0
Lathyrus odoratus, Sweet Pea	Number of blooms	780.0	3,433.0	2,777.0	3,591.0
Trees.					
Elm, American	Average gain in diameter in four years	2.1	2.6	2.6	3.0
Peach, Early Crawford	Average gain in diameter in four years	2.7	3.1	3.0	2.8
Plum, Burbank, Japanese	Average gain in diameter in four years	1.1	1.6	1.6	1.9
Spruce, Norway	Average gain in diameter in four years	1.5	1.1	1.7	1.4
Small fruits.					
Blackberry, Snyder	Pounds of fruit	30.2	52.1	30.2	17.5
Currant, Prolific	Pounds of fruit	1.3	5.2	2.5	8.5
Cranberry, American Bell	Pounds of vines	1.7	0.3	1.5	0.3
Raspberry, Blackcap	Pounds of fruit	5.1	3.2	7.0	2.9
Raspberry, Cuthbert	Pounds of fruit	6.0	12.8	7.0	8.8
Vegetables.					
Asparagus	Pounds	0.0	9.2	2.1	14.3
Beet, Eclipse Table	Pounds	0.2	164.2	70.1	196.0
Lettuce, Butterhead	Pounds	0.02	44.4	5.3	50.8
Cantaloupe, Netted Gem	Pounds	0.0	88.8	30.8	116.0
Watermelon, Phinney	Pounds	223.8	166.3	364.1	230.5
Onion, Large Red Wethersfield	Pounds	0.3	41.5	24.0	44.3

It is of interest to note the poorer result with *Silene orientalis* where the soil was made more nearly neutral or alkaline, and the almost fatal effect of liming on the cranberry vines. This result should be compared with that with the sweet peas and beans. H. J. Wheeler.

LIME (Fruit). The acid lime (*Citrus aurantifolia;* see volume II, page 782), Fig. 2175, is found in most parts of the tropics, and is commonly cultivated or found growing in a semi-wild state in India, Ceylon, the Malay Archipelago, West Indies, tropical Mexico, and to a lesser extent on the Keys and in the warmer parts of Florida. The West Indian Islands, Montserrat and Dominica, are noted for their commercial production of lime fruit, lime juice and citrate of lime. In California, the lime is grown as a home fruit in some parts, but as it does not possess the hardiness of the orange or lemon, it is of no commercial importance. The sweet lime (*C. limetta*) is perhaps a hybrid, worthless as a commercial fruit in America, though grown and used in other countries.

In the eastern United States, the limes so largely used at the soda fountains are secured mostly from the West Indies, packed in barrels and imported via New York, although part of the supply comes from the Florida Keys. The supply of the western states comes from Mexico, for the most part. These limes, the product of seedling trees, are variously referred to as Mexican, West Indian or Key limes. In tropical countries, where limes may be secured at all seasons of the year, they are used almost entirely in place of lemons, and each year it is becoming a more important fruit throughout America. There is no doubt but that it will eventually occupy a much larger place in our markets.

The cultivation of the lime is confined to regions where frosts are practically unknown. In the dormant or winter season, the trees respond very readily to rising temperatures, new and very tender growth starts and if a drop in temperature sufficient to cause frost follows, as it so often does in many regions where its culture has been tried, the trees suffer severely. Attempts are being made to secure a hardy fruit by crossing with the kumquat (see *Limequat*).

Of the varieties in cultivation, Tahiti and Persian are much the same. The fruits are as large as ordinary lemons. These are somewhat hardier than the smaller-fruited seedling Mexican limes. Palmetto and Everglade are two varieties of Mexican limes, originated, named and described by H. J. Webber, (Yearbook United States Department of Agriculture, pages 279–281, plate XX, 1905). These have neither been introduced nor planted commercially. Their merits in a large way are therefore unknown. There is no question but that the careful selection, and propagation by budding, of Mexican limes would be well repaid. Thornless is a recently introduced variety from Dominica of the Mexican type. The absence of thorns is a desirable feature. Bearss and Imperial, of the same general type as Tahiti, are grown in California. In the colder citrous sections the true limes may be replaced by the calamondin (*Citrus mitis*), a very prolific citrus which produces a small acid fruit of excellent flavor, resembling a small tangerine in color, shape and rind. Rangpur is an acid fruit, the size of a small lemon, round or oblate, orange-red in color, with deep orange-colored flesh, high quality and excellent flavor. It is often referred to as a lime from which it is distinct. Bonavia refers it to the Suntara orange group of India. It is hardier than the true limes, in fact it ranks with the sweet oranges in this respect and is worth planting where the true limes cannot be grown.

The Mexican lime, grown as seedlings, is not particular in its soil-requirements. It grows and seems to flourish on poor sandy soils, or on rocky soils. It will grow and bear fruit in considerable quantities even when neglected and left unfertilized and uncultivated. These limes are produced in Florida on the lower East Coast and on the Keys, where an association has been formed for handling the crop. In other parts of South Florida, Tahiti and Persian have been planted in groves, in considerable numbers, and the fruit thus far has sold at good prices for local consumption.

Limes may be grown as seedlings or they may be propagated by budding on sour orange or rough lemon seedlings.

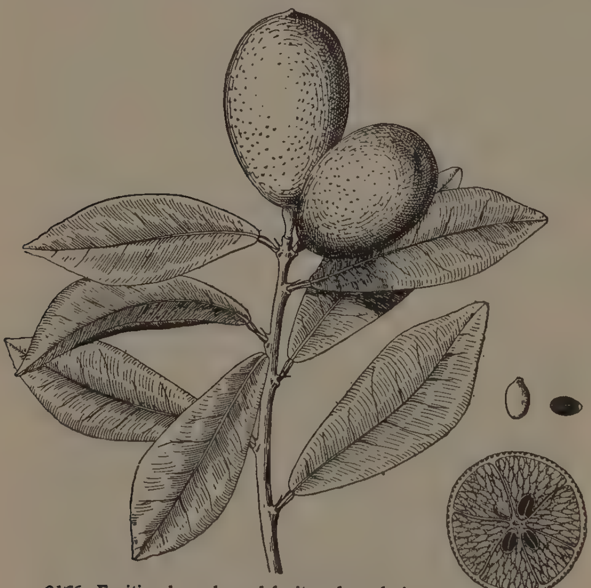
In orchard plantings, the seedlings are set 12 to 15 feet apart each way and the budded trees about 20 feet. The cultivation, fertilizing and general care are the same as for other citrous fruits.

The fruit is gathered when full grown, but while still green, packed and shipped immediately. Carefully handled, they keep well, but do not usually stand up so long as processed or cured lemons. It is sometimes stated that the Tahiti lime is a poor keeper. This is often due to the attacks of fungous diseases which can be guarded against.

They are attacked by the ordinary citrous insects. Anthracnose or wither-tip is the most serious fungous pest. This destroys the smaller twigs and branches and produces hard wart-like spots on the Mexican lime fruit. It may be held in check by careful pruning out of dead and diseased wood and by spraying with bordeaux mixture.

H. Harold Hume.

LIMEQUAT (from lime and [kum] quat). Fig. 2176. Hybrids between the common lime (*Citrus aurantifolia*) and the oval or round kumquats (*Fortunella margarita, F. japonica*). This new and promising citrous fruit was originated by the writer in 1909 by crossing the common West Indian lime with the kumquat. While the lime is the tenderest of all commonly grown citrous fruits and is frequently frozen to the ground even in southern Florida, the kumquat, because of its remarkable winter dormancy, is one of the hardiest of the evergreen citrous fruit trees. The limequat possesses in large measure the cold-resistance of the kumquat and can be grown in regions too cold for the lime. The limequat also shows resistance to citrus canker, a destructive bacterial disease, caused by *Pseudomonas citri*. Limequats vary in size, some being no larger than a large kumquat, while others are the size of a lime. The skin is thin and has an agreeable aroma and flavor; the pulp is juicy and pleasantly acid. This hybrid, which fruited for the first time in 1912, is a vigorous grower and a heavy bearer. It is being tested in the South.



2176. Fruiting branch, and fruit and seeds in cross-section, of an oval limequat. (×½)

Walter T. Swingle.

LIMNÁNTHEMUM: *Nymphoides.*

LIMNÁNTHES (Greek, *marsh flower*). *Limnanthàceæ.* A few species of American annuals growing near the water. Low, diffuse, rather fleshy: lvs. pinnately dissected: fls. white, yellow or rosy, solitary on axillary peduncles, regular, the parts in 4's–6's; sepals valvate in the bud; glands alternating with the petals; stamens usually 10: carpels distinct or nearly so, at first fleshy, at length hard and wrinkled, indehiscent, separating from the short axis; ovule solitary. By some authors this genus is kept in Geraniaceæ, but this and Floerkea are by others separated in a small family Limnanthaceæ. The two genera are sometimes combined, but Floerkea is 3-merous and Limnanthes is commonly 5-merous, and there are other differences.

Doúglasii, R. Br. (*Floérkea Doúglasii,* Baill.). Meadow Foam. Spreading, branched and glabrous yellow-green low herb with handsome white-yellow fragrant fls. nearly 1 in. across, cult. as a garden annual: about 1 ft. high: lvs. pinnate; lfts. sharply lobed or parted: petals oblong-spatulate, notched at apex, more or less yellow, white toward the tip: fr. smooth or slightly corrugated. Calif., Ore. B.M. 3554. B.R. 1673. Gn. 72, p. 611. G. 4:3.—The fls. vary somewhat in color: usually the petals are white with yellow toward the base; sometimes roseate and yellow. *L. grandiflòra* (fls. larger) and *L. sulphùrea* are garden names. The plant is easy of cult.

L. H. B.

LIMNÒBIUM (*living in pools,* from the Greek). *Hydrocharitàceæ.* American aquatic herbs, one of which is in the trade.

Stemless plants, spreading by means of runners, the large lvs. floating: monœcious, the fls. arising from spathes borne on the rootstock, the pistillate single from a spathe and the staminate 2–4 from a spathe, all with 6 white segms. or petals, the inner ones being very narrow; stamens in a column, bearing anthers at unequal heights; ovary with several (6–9) locules and as many stigmas, ripening into a many-seeded berry. As defined by some writers, the genus comprises a single species, *L. Spongia;* others unite with it the diœcious Hydromystria (incl. Trianea), 2 or 3 species of Trop. Amer.

Spóngia, Rich. (*Hydrócharis Spóngia,* Bosc. *L. Bósci,* Rich.). American Frogbit or Frog's-bit (the European Frogbit is Hydrocharis). A neat floating plant, with purplish, hanging, hairy roots and long-stemmed, orbicular, cordate or ovate lvs. 1–2 in. long and purplish beneath. Lake Ontario to Fla. and Texas.—Good for the aquarium. According to William Tricker, its mottled foliage and silky rootlets are very attractive and make it valuable in small areas or tanks, but when grown out-of-doors in summer in tubs or pools, it is very vigorous and soon becomes crowded; the lvs. instead of floating, then appear in an erect state, the spongy condition of floating lvs. having disappeared; it is really a floating plant, prop. by division of runners, and should not be placed in shallow water, where it can readily root into the soil.

L. stoloniferum, Griseb. (Hydromystria stolonifera, Mey. Trianea bogotensis, Karst.), is more sturdy in habit, of a lighter color—especially in winter—does not make such long runners, and forms more compact and attractive rosettes of lvs. Mex. to Paraguay; Trinidad.

L. H. B.

LIMNÓCHARIS (from Greek, referring to marsh habitat). *Butomàceæ.* Water plants, suitable for aquaria and for plunging in pools in summer.

Perennial aquatic herbs, stoloniferous, with lanceolate or ovate, petiolate, emersed lvs.: fls. perfect; sepals 3, persistent; petals 3, thin, fugacious; stamens numerous, the outer ones sterile: carpels 15–20, verticillate, style none, stigma sessile and extrorse.—Two species are admitted by Buchenau, (Engler's Pflanzenreich, hft. 16. 1903), both tropical American. From Hydrocleis it differs in its more numerous verticillate carpels, no style and different stigmas.

flàva, Buchen. (*L. Plumièri*, Rich. *L. emarginàta*, Humb. & Bonpl. *Alísma flàvum*, Linn.). Sts. erect, angled, 10–16 in. high in bloom: lvs. erect, standing out of the water, the blade from lanceolate to broad-ovate, cuneate or cordate at base: fls. in umbel-like clusters of 2–12, the peduncle 3-angled and toward the top 3-winged; sepals broadly ovate and obtuse, greenish; petals broadly ovate or orbicular, yellow: carpels 15–20, scarcely cohering. W. Indies and S. Amer. B.M. 2525.—*Limnocharis flava* is entirely distinct from *Hydrocleis nymphoides* (which see). The light green oblong, blunt lvs. are very characteristic and ornamental; petiole triangular, 1–2 in. high: the fls., produced on a scape, are pale yellow bordered white. Seed is produced very freely, and as the seed matures the scapes fall to the water, the seed ripens and sinks to the bottom, and when grown out-of-doors, sometimes renews itself the following season. The fl.-scape, as soon as it rests on the water, throws up a shoot, which produces another plant in a short time, which again produces fls., seeds and shoots, and so on. The plant may be grown in pots or tubs or planted out in shallow water in early summer.

William Tricker.
L. H. B.

LIMODÒRUM (*meadow gift*, from the Greek). *Orchidàceæ*. A name adopted by some authors for what has been known as Calopogon, comprising a half-dozen species of scapose cormous herbs bearing attractive rose or purple (rarely white) fls. in a spike or raceme. Transferred to this genus, the grass-pink (*Calopogon pulchellus*) is given the name *L. tuberòsum*, Linn. All the species are found in E. N. Amer., from Newfoundland to Cuba and the Bahamas. *L. tuberosum* is sometimes transferred to bog-gardens; see Calopogon for cult. A southern species, *L. multiflòrum*, Mohr, growing in Fla., is recommended for bog-planting S. The single lf. is linear: scape to 16 in. tall, bearing deep purple fls.; lateral sepals ovate, acute; petals ovate or obovate; middle lobe of lip broad-cuneate, about ⅓in. wide.

L. H. B.

LIMÒNIA (derivation uncertain). *Rutàceæ*. An invalid generic name usually misapplied to *Hesperethusa crenulata*, which see. A number of species belonging to very diverse genera were formerly placed in Limonia. See *Feronia*.

L. acidíssima, Linn.=Feronia Limonia.—*L. acidíssima*, Auct. (not Linn.)=Hesperethusa crenulata.—*L. angulòsa*, Wight & Arn.=Merope angulata.—*L. biloculàris*, Roxbg.=Severinia buxifolia.—*L. crenulàta*, Roxbg.=Hesperethusa crenulata.—*L. Demeùsei*, De Wild.=Citropsis Preussei (?).—*L. Engleriàna*, Perkins=Chætospermum glutinosa.—*L. gabonénsis*, Engler=Citropsis gabonensis.—*L. glutinòsa*, Blanco=Chætospermum glutinosa.—*L. Lacourtiàna*, De Wild.=Citropsis gabonensis(?).—*L. monophýlla*, Roxbg.=Atalantia monophylla.—*L. pentaphýlla*, Retz.=Glycosmis pentaphylla.—*L. Póggei*, Engler=Citropsis Schweinfurthii(?).—*L. Preùssei*, Engler=Citropsis Preussei.—*L. scándens*, Roxbg.=Lavanga scandens.—*L. Schweìnfurthii*, Engler=Citropsis Schweinfurthii.—*L. spinòsa*, Spreng.=Merope angulata.—*L. trichocárpa*, Hance=Poncirus trifoliata.—*L. trifòlia*, Burm.=Triphasia trifolia.—*L. trifoliàta*, Linn.=Triphasia trifolia.—*L. ugandénsis*, Baker=Citropsis Schweinfurthii.—*L. Warnéckei*, Engler=Balsamocitrus paniculata.

Walter T. Swingle.

LINÁNTHUS (*flax flower*). *Polemoniàceæ*. By Gray, Peter and others included in Gilia as a section or subgenus, but by some authors kept distinct. *L. densiflòrus*, Benth., is described on page 1337 as *Gilia densiflora*. It is advertised as "California phlox." It is an old garden annual, very attractive when sown thickly as it makes a mass of lilac bloom. The plant is native in the Coast ranges and valleys of Calif.

About a dozen West American gilias are now included in this genus by some writers, one other of which, *L. androsàceus*, Greene (*Gilia androsàcea*, Steud., p. 1337), is sometimes grown as a flower-garden annual.

L. H. B.

LINÀRIA (*Linum*, flax, which the lvs. of some species resemble). *Scrophulariàceæ*. Low herbs, sometimes subshrubs, several species cultivated for the oddly irregular flowers and others for the festooning foliage.

Annual, biennial, perennial: lvs. alternate, or sometimes subverticillate, in the erect-growing species mostly narrow and entire: fls. solitary in the axils, or in terminal racemes, yellow, white, blue or purple; corolla personate or grinning, 2-lipped, usually 1-spurred at the base (in rare or so-called peloria states 5-spurred); stamens 4, ascending in 2 pairs, slender; style 1: fr. a dry caps., opening by slits or pores near the summit, many-seeded.—Widely distributed, mostly in temperate parts of the northern hemisphere, of more than 100 species and with many hybrids. Occasionally the fls. of the common toad flax (*Linaria vulgaris*) are regular. When Linnæus discovered this form, he took the plant to be of another kind and used for it the genus Peloria. This word Peloria is now used generically for the regular state of any normally irregular fl. Such monstrosities occur now and then, particularly in the Scrophulariaceæ.

In America, linarias are little known as garden plants, although they are worthy greater attention. They are of two general classes,—the hardy perennials (sometimes evergreen) and the annuals. The perennials are propagated by seeds and by division, usually the latter. All the species are of easiest culture in any ordinary soil and exposure, and are largely able to shift for themselves when once established. The annuals may be started indoors; or in warm situations they may be sown where the plants are to stand. Some of the trailing and cespitose species are good for rock-gardens.

A. *Plant completely trailing: lvs. palmately veined and lobed. Subgenus Cymbalaria.)*

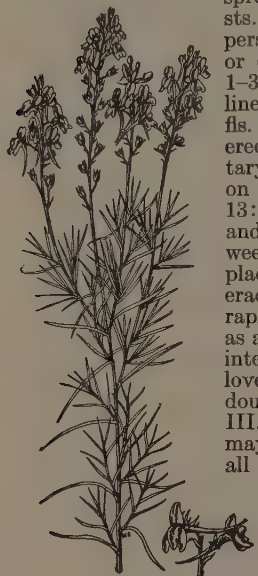
1. **Cymbalària,** Mill. (*Antirrhìnum Cymbalària*, Linn.). Kenilworth Ivy. Mother-of-Thousands. Perennial tender glabrous herb, but sowing itself freely from seeds, long-trailing and rooting at the joints: lvs. cordate-orbicular or reniform, 5–7-rounded-lobed, on slender stalks longer than the blades: fls. solitary on the axils, on slender sts., small but pretty, lilac-blue with a yellowish throat: caps. globular, splitting from the top. Eu. Var. **álba,** Hort., has white fls. Var. **rósea,** Hort., has pale pink fls. Var. **máxima,** Hort. (*L. pállida*, Hort.), has large light-colored fls. Var. **globòsa,** Hort., forms a compact globular plant: fls. lilac.—The Kenilworth ivy is one of the most familiar of trailers on greenhouse bottoms and in odd corners; also as a trailing basket-plant in greenhouses and dwelling-houses. It is of the easiest cult., particularly in a moist and partially shaded place. Prop. by division of the long sts. or by seeds. It will not stand frost, but the plant will spring up year after year from seed, becoming essentially annual. It has become established in the open in many parts of the E. It is a good basket-plant for poorly lighted places and is a continuous bloomer. By some botanists, it is made the type of the genus Cymbalaria

2. **æquitríloba,** Spreng. Close-growing creeping evergreen, perennial, with long trailing branches: lvs. small, roundish or reniform, fleshy, mostly opposite, entire or with 3–5 short mucronate lobes: fls. pale mauve on pedicels nearly equaling the lvs.; palate large, reddish purple; calyx-segms. very narrow. S. Eu. B.M. 2941.

AA. *Plant erect or nearly so (sometimes decumbent at base): lvs. long.*

B. *Fls. yellow.*

3. **vulgàris,** Mill. (*Antirrhìnum Linària,* Linn.). TOAD-FLAX. BUTTER-AND-EGGS. Vigorous perennial, spreading freely by underground sts. and in time forming large and persistent patches: sts. strict, nearly or quite simple, slightly glaucous, 1–3 ft. high: lvs. many, scattered, linear, somewhat narrowed below: fls. in a terminal spicate raceme, erect-spreading, with hanging nectary spur, sulfur-yellow, but orange on the bearded palate. Eu. A.G. 13:469.—Extensively naturalized, and commonly regarded as a bad weed; but it infests chiefly waste places, and although difficult to eradicate it does not spread very rapidly. Now and then it appears as an ornamental plant. It is more interesting to the general plant-lover than to the gardener. A double-fld. form is figured in G.C. III. 18:554. The peloria forms may have 5 spurs, or no spurs at all (R.H. 1851:433).



2177. Linaria bipartita. (×⅙)

4. **macedónica,** Griseb. Robust perennial (perhaps sometimes annual): 2–3 ft. high, branching, grayish green: lvs. narrow-ovate or the upper ones lanceolate, somewhat cordate at the base, nearly or quite sessile, entire: fls. bright yellow, with deeper color on the palate, in long wand-like terminal racemes. Macedonia; perhaps a broad-lvd. form of *L. dalmatica.* Gn. 45:110. J.H. III. 30:469.—A good hardy plant, bearing its snapdragon-like fls. most of the season. Var. **speciòsa,** Hort., is a showy form or strain with large lemon-yellow fls. bearing an orange-yellow mark on lower lip: 2–3 ft.: blooms the first year from early-sown seeds, giving excellent cut-bloom.

5. **dalmática,** Mill. Stout erect perennial, 3–4 ft., forming a large clump: lvs. glaucous, oblong-lanceolate to linear-lanceolate, acute: fls. large, bright yellow, borne at the tops of the branches in a long loose spike; spur straight, much exceeded by the corolla. S. E. Eu. —It is probably to this species or to the last (No. 4) that *L. hybrida* and other garden yellow-fld. forms belong.

BB. *Fls. blue or purple (running to white in some cases).*

C. *Perennial border plants.*

6. **alpìna,** Mill. Compact-tufted plants, 6 in. or less high, with weak and spreading fl.-sts.: lvs. linear or lanceolate, mostly in 4's: fls. in short racemes or heads, blue with an orange-colored palate, the straight or slightly curved, sharp spur as long as the corolla. Alps. F.S. 20:2128. G.C. II. 14:105.—A pretty little alpine, blooming in July and Aug. Var. *nàna ròsea,* Hort., is said to be a dwarf and very distinct form.

7. **triornithóphora,** Willd. (*Antirrhìnum triornithóphorum,* Linn.). Fig. 2178. Glaucous, 2–3 ft. tall: lvs. ovate-lanceolate, in 3's or 4's: fls. about 3 in a whorl (hence the name, *bearing three birds*), rather large, slender-stalked, violet- and purple-striped, with orange palate, about 1 in. long, the spur inflated above and exceeding the lobes. Spain, Portugal. B.M. 525. F.S. 22:2297. H.U. 3:100.—A handsome and interesting plant, rarely seen in American gardens.

8. **rèpens,** Mill. Erect, or decumbent at base, bushy, 1–2 ft. or more, glabrous, with slender creeping rootstock: lvs. whorled or crowded near the base but scattered above: fls. not large, fragrant, in short racemes, forming a terminal panicle, nearly white but striped with purplish veins; corolla less than ½in. long; spur variable, usually short and conical. Eu.—The *L. repens alba* of lists may belong here. *L. repens* is sometimes adventive in this country.

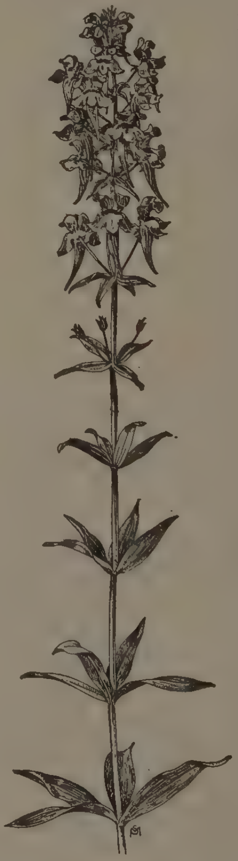
9. **purpùrea,** Mill. (*Antirrhìnum purpùreum,* Linn.). Erect, branched glabrous perennial, 1–3 ft.: lvs. linear or linear-lanceolate, mostly whorled: fls. bright purple, in long racemes, the throat bearded with white hairs, the tube striped; spur about the length of corolla, curved; calyx-lobes linear-acute. S. Eu. B.M. 99.

10. **origanifòlia,** DC. Perennial (sometimes described as annual), ascending, 8–10 in.: lvs. oblong or obovate, short-stalked, the upper alternate and lower opposite: fls. pale purple, rarely white, yellow in the throat, in a slender loose raceme; calyx-lobes linear or linear-spatulate, villous. S. Eu.

CC. *Annual plants of the fl.-garden.*

(See R. H. 1896, pp. 371–4.)

11. **bipartìta,** Willd. Fig. 2177. A foot high, erect, branching, with scattered or verticillate linear lvs.: fls. large, in a long racemose spike, violet-purple, with the palate orange-colored above and whitish toward the base, the spur curved, about as long as the corolla, standing oblique or horizontal; upper lip parted. Portugal, N. Afr.—Old-time annual, but it has never been popular in N. Amer. Var. **álba,** Hort., has yellowish white fls. Gn. 74, p. 203. Var. **spléndida,** Hort., has handsome deep purple fls. There is also a var. **striàta,** Hort. The Excelsior forms probably belong here or with No. 12.



2178. Linaria triornithophora, an old-fashioned plant. (×½)

12. **maroccàna,** Hook. f. Plant annual: spike much shorter and denser than in *L. bipartita:* fls. bright violet or rose, with a whitish palate, the spur long, pointed, as long as the pedicel and usually hanging nearly parallel with the axis of the spike: lvs. many, linear, scattered or whorled, hairy. Morocco. B.M. 5983. A var. **ròsea,** Hort., is mentioned, with deep carmine-rose fls.

13. **reticulàta,** Desf. Fls. pubescent, purple, reticulated with purple, the palate yellow or copper-yellow, the spur pointed and shorter than the corolla and pointing downward: spike short: lvs. linear, scattered or verticillate. Portugal. J.F. 3:260.—An old garden plant, but little known in Amer. Runs into two or three forms.

14. **heterophýlla,** Desf. (*L. aparinoìdes,* Dietr.). Annual, erect, 2–3 ft., with scattered linear or lanceolate, somewhat fleshy, lvs.: fls. straw-colored, with a yellow palate, in spicate racemes more or less branching at base; calyx-lobes linear and obtuse or somewhat acute. Morocco, Sicily, etc. B.M. 6041. Var. **spléndens,** Hort., with violet-bronze fls., is mentioned, possibly a hybrid.

L. Broussonnéttii, Chav. (L. multipunctata, Hoffmgg.). Low annual, with yellow, black-spotted fls., orange on the palate, and lanceolate or linear lvs.: 5–8 in. high, mostly upright. Spain.—*L. canadénsis,* Dum., is a weedy native plant, of no value to the garden, although sometimes making a considerable show in fields in spring: it is annual or biennial, strict, 1–2 ft., with very small blue fls.—*L. globòsa*, Hort. Described as making close rounded masses, with glaucous-green lvs. and lilac fls. L. Cymbalaria(?).—*L. hepaticæfòlia*, Steud. A good alpine, making a very low mat: fls. purple: lvs. cordate or reniform, lobed. Corsica, Sardinia.—*L. multipunctàta*, Hoffmgg.=L. Broussonettii.—*L. Pancici*, Hort. (not Janka), is said to be a beautiful dwarf species with large canary-yellow fls. and narrow-lanceolate lvs., from the Orient.—*L. petræa*, Jord. Low plant, with rose-colored fls. tinged violet and yellow on the tip. Eu.—*L. saxátilis*, Hoffmgg. & Link. Rockwork perennial, trailing, with thickish lanceolate lvs., and yellow fls. in short clusters. Spain.

L. H. B.

LINDELÒFIA (Friedrich von Lindelof, a German patron of botany). *Boraginàceæ.* Two species of erect hardy herbaceous perennials from the high Himalayas, one cultivated for the flowers resembling forget-me-not.

This genus has the habit and nutlets of Cynoglossum, but the stamens of Cynoglossum are included, while those of Lindelofia are exserted: lvs. radical and cauline, the latter alternate and ovate to linear-lanceolate: fls. blue or purple, often very dark, in long dense racemes; sepals somewhat enlarged in fr.; corolla with cylindrical tube and cone-like scales in the throat, the lobes obtuse; stamens 5, with large linear-oblong anthers; ovary 4-lobed: nutlets with hook-tipped bristles.

longiflòra, Gürke (*L. spectábilis*, Lehm. *Cynoglóssum longiflòrum*, Benth.). Pilose: lvs. oblong-acuminate, the upper ones heart-shaped or clasping at the base: fls. deep blue; tube ¼in. long and lobes shorter. B.R. 26:50. J.H. III. 31:235. Var. **afghânica**, Hort., is offered, 1 ft., of spreading habit. G.W. 10, p. 90.—The species is variable, particularly in size of corolla. It usually grows about 2 ft., flowering freely in May and later. The racemes are about 6 in. long, and have 8–12 fls. The plant is likely to be winter-killed unless given a sheltered place, good drainage and winter covering. It is not fastidious as to soil. Easily prop. by division. It seeds freely and flowers the second year from seed.

Wilhelm Miller.
L. H. B.†

LINDEN: *Tilia.*

LINDENBÉRGIA (J. B. W. Lindenberg wrote on the liverworts, 1829). *Scrophulariàceæ.* About 16 annual or perennial herbs of tropical or warm parts of Asia and Afr., differing from Mimulus in having a campanulate rather than tubular calyx and the anther-cells separate: corolla 2-lipped, the tube cylindrical; upper lip short and broad, emarginate or lobed; lower lip larger, 3-lobed and spreading; stamens 4, didynamous, included: caps. oblong or ovoid, dehiscent: plant decumbent or ascending, sometimes woody at base, with opposite dentate lvs. (or the upper ones alternate): fls. nearly sessile, solitary or in terminal racemes or spikes, the bracts leafy. **L. grandiflòra**, Benth., has recently been mentioned in horticultural literature abroad. It is a good greenhouse plant in England, with yellow fls.: soft-hairy, somewhat scandent: lvs. ovate, acuminate, coarsely serrate: fls. 1 in. long, in terminal leafy spikes. Himalaya, to 6,000 ft. altitude. B.M. 7738. G.C. III. 32:213; 53:27. G.M. 45:616; 56:41. G. 24:671.—Mentioned sometimes as annual, but it is perennial in cult. It is a valuable winter-blooming plant, keeping in good condition 3 months, and may be grown in compact bushy form by being cut back.

L. H. B.

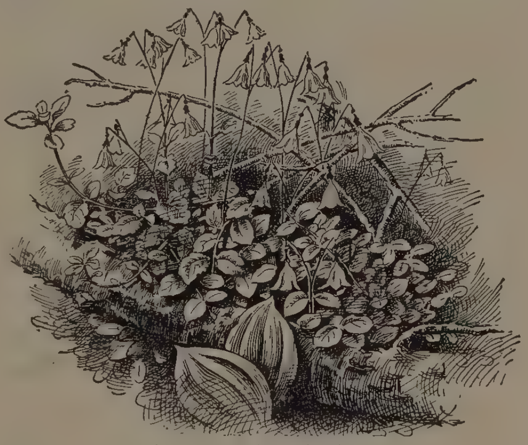
LINDÈRA: *Benzoin.*

LINDSÀYA (Archibald Lindsay, early English botanist). Sometimes spelled *Lindsæa*. *Polypodiàceæ.* About thirty species of tropical ferns, of both hemispheres, none of which is advertised in Amer. They are very difficult of cultivation, and are apparently adapted only as fancier's plants. Schneider, in his "Book of Choice Ferns," says they usually die soon after importation, even if apparently in good condition on arrival. In their native habitat, he says, these ferns usually creep about in poor, stony soil, which is frequently drenched and washed away by rain. They need a high temperature and humid atmosphere. Some success has been attained by placing lindsayas in pots nearly filled with crocks, in which they are firmly held by two or three pieces of turfy loam, and by imitating in other ways the natural conditions described above.

LINNÆA (named after Linnæus, at his own request; it was his favorite flower). *Caprifoliàceæ.* Twin-Flower. Ornamental hardy plant grown sometimes for its delicate pink or purplish flowers.

Evergreen trailing subshrub: lvs. opposite, small, crenate, petioled, without stipules: fls. in pairs on slender upright peduncles; calyx 5-parted; corolla campanulate, 5-lobed; stamens 4; ovary 3-celled: fr. dry, indehiscent, 1-seeded.—Only one species in the colder regions of the northern hemisphere. There is an interesting monograph of this variable species by Wittrock in Acta Hort. Berg. 4, No. 7, 187 pp., 13 pl. (1907), where about 150 varieties are described and figured.

The twin-flowers are half-woody plants with trailing slender thread-like stems, small, usually roundish persistent leaves and slender-stalked, nodding, pinkish or nearly white, campanulate twin flowers. They are hardy North and are graceful, dainty plants for rockeries, preferring a shaded moist position and porous, peaty or humous soil. Propagation is usually by division or by cuttings of soft or half-ripened wood under glass.



2179. Linnæa borealis. (×¼)

boreàlis, Linn. Fig. 2179. Sts. slender, slightly pubescent: lvs. short-petioled, roundish or obovate, with few crenate teeth, usually ciliate and with scattered hairs above, ¼–¾in. long: fls. pedicelled in 2's at the top of slender, upright peduncles; corolla rose-colored or white, ⅓–½in. long, fragrant, in the typical form campanulate, with the constricted portion at the base much shorter than the calyx. June–Aug. N. Eu. and N. Asia. Gn. 24, p. 177. G. 1:536. M.D.G. 1910:138. Var. **americàna**, Rehd. (*L. americàna*, Forbes). Differs chiefly in the corolla being distinctly tubular at the base, the tubular part exceeding the calyx: lvs. usually glabrous, but ciliate near the base. N. Amer., Lab. to Alaska, in the mountains south to Md. and Calif. B.B. (ed. 2) 3:276. Var. **longiflòra**, Torr. (*L. longiflòra*, Howell). Fls. more funnelform, ½in. long or slightly longer; peduncles 2–3 in. long: lvs generally somewhat larger. Wash. to Calif. A var **màjor** is listed. In Fig. 2179, the two large lvs. in the foreground do not belong to Linnæa.

For *L. floribúnda*, Braun & Vatke, and other species, see Abelia.

Alfred Rehder.

LINNEÀRA (named apparently for Linnæus). *Orchidàceæ.* The Rules of Horticultural Nomenclature adopted by the subsection of Nomenclature at the International Horticultural Congress at Brussels, 1910, provide that "multigeneric hybrids receive a conventional generic name, preferably that of a distinguished man, to which is added the termination *ara.* A distinct generic name will be formed for each different combination of genera. Thus all combinations of the genera Brassavola, Cattleya, Lælia and Epidendrum, no matter in what order they may be intercrossed, receive the same generic name which would be, for example, *Linneara.*" The Royal Horticultural Society (London) had proposed to the Congress that "Future multigeneric hybrids (combining three or more genera) should be given a conventional name consisting of the name of some person eminent as a student or as a grower of orchids, followed by the termination 'ara'." "A separate generic name should be coined for each distinct combination of genera. Thus, Brassocattleya × Epilælia, and Brassodendrum × Brassocattleya, and Brassolælia × Epicattleya, and Brassolælia × Epidendrum, and all other possible combinations of those four genera would be designated by one name, e.g., *Adamara,* while a second generic name, e. g., *Linneara,* would need to be coined for Dialælia × Brassocattleya, and this would stand for all combinations of the four genera Diacrium, Lælia, Brassavola, and Cattleya."

The Congress adopted Linneara for the hybrids of the genera Brassavola, Cattleya, Lælia, Epidendrum. The name Adamara was not adopted. Neither name has become current; see also *Lowiara.* L. H. B.

LINOSPÀDIX (Greek, *linear spadix*). *Palmàceæ.* Dwarf unarmed palms varying considerably in foliage.

Flowers monœcious, spirally arranged on the erect spadix which appears among the lvs.: lvs. terminal, flabelliform, deeply 2-cut, the apex of the lobes sometimes cut and thread-like.—Eight species all from New Guinea. The genus is allied to Bacularia, but Bacularia has premorse lf.-segms. and erect anthers fastened at the base, while Linospadix has acuminate lf.-segms. and versatile anthers fastened on the back. Linospadix is distinguished from Howea (which see) by the stamens 6–9; pistillate fls. with 6–9 staminodes: ovule parietal. The best known species, *L. Petrickiana,* is of uncertain botanical affinity. The name does not appear in botanical literature. This is a handsome pinnate-lvd. palm of compact growth and well furnished with foliage, at least while in a young state. In its juvenile condition, the lvs. of *L. Petrickiana* are simply bifid, the pinnate form gradually appearing as the plant attains age. It was intro. in 1899 by Sander & Co., who say: "The slender, alternate pinnæ are slightly arched. The base is netted with brown fiber, small, hair-like glumes of the same color being apparent on the younger fronds and leafstalks. The young fronds are colored similarly to those of *Areca Ilsemannii,* and when developing have the luster and brilliancy of new copper." Cultural conditions suited to the needs of calamus and dæmonorops will be most likely to succeed with linospadix, and include a temperature of 70°, plenty of water, and some shade throughout the year.

Petrickiàna, Hort. Sander. Pinnæ once cut from the apex to a third or fourth the length of the pinna; laterally cut about six-sevenths of the way from the tips of the segms. to the rachis: premature basal lvs. cut once from the apex to half their length, the 2 lobes uncut. G.C. III. 24:299.

L. Leopóldii, Hort. Sander. Uncertain as to botanical affinity, perhaps the preceding. Name never published in botanical literature. Shown at Ghent in 1903. G.C. III. 33, suppl. to April 25. —*L. Micholítzii,* C. H. Wright. A low, stemless palm, with a densely crowded cluster of 2-cut, flabelliform, plicate lvs.: spadix slender, nodding, about 1–2½ ft. long, bearing numerous attractive, pale yellow fls. New Guinea. B.M. 8095. Not in cult. in Amer., but an attractive little plant. N. TAYLOR.

LINÓSYRIS (*Linum* and *Osyris,* which genera it resembles). *Compósitæ.* One species, **L. vulgàris,** Cass., GOLDILOCKS, of Eu., is a good hardy perennial, growing ½–2 ft. high, and bearing numerous small pale yellow usually rayless heads: sts. strict (from a hard root), striate, glabrous, bearing many alternate, small, linear, entire lvs.: involucre imbricated, the numerous narrow bracts shorter than the florets and pappus: achene compressed and silky. The plant grows natively in rocky and stony places and along gravelly banks of rivers in England, Wales, and through Cent. and S. Eu. to the Caucasus. It is an excellent late summer and fall bloomer, thriving well in any good garden or border. Prop. by division.

The genus Lynosyris is referred to Aster by many botanists, the above species then becoming *Aster Linosyris,* Bernh. It is also known as *Chrysocoma vulgaris,* Linn. Horticulturally, it is distinct, with its yellow heads and peculiar habit. From Aster it differs technically in the absence of rays and in yellow flowers, but rayed heads are sometimes found. In this work, the yellow-flowered asters are kept distinct in this genus and Calimeris. As usually separately defined, Linosyris contains several species. L. H. B.

LÌNUM (classical name). Including *Cathartolìnum. Linàceæ.* FLAX. Ornamental flowering plants, annual and perennial; one is the fiber-yielding flax.

Erect-growing plants, bearing tough cortex, with narrow alternate (rarely opposite) and mostly entire lvs., and showy 5-petaled fls. which open in the sunshine: stamens 5 and alternate with the petals, usually united at the base, staminodia sometimes present: ovary single, 3–5-loculed, bearing as many styles as locules, and ripening into a dry caps. which may or may not be dehiscent: fls. red, blue, yellow, white, borne in terminal racemes or cymes, and, although each fl. may be short-lived, the continuity of bloom makes the plant showy.—Species 90–100, in temperate and warm regions about the globe, about one-fourth of which are in the U. S.. There are two horticultural sections,—the annuals and perennials. All are of easy cult. in an open and warm place, fully exposed to the sun. Seeds of the annuals may be sown where the plants are to bloom or they may be started under glass. The perennials often bloom the first year from seed, and seeds are often used to prop. them; but the plants may be divided. The species with capitate stigma and glandular sepals, mostly yellow-fld., are by some authors separated as Cathartolinum.

A. *Plant annual: fls. red or blue.*

B. *Bloom of the red series.*

1. **grandiflòrum,** Desf. FLOWERING FLAX. Fig. 2180. Erect, branchy, 1–2 ft., glabrous: lvs. many, alternate, broadly lanceolate to oblong, sessile or nearly so: fls. terminating very slender pedicels which are 1–3 in. long, the obovate petals wide-spreading (fl. 1–1½ in. across, and something like a single-fld. pink) and much exceeding the pointed scarious-edged sepals. N. Afr. B.M. 4956. R.H. 1848:401.—Very serviceable garden annual, and popular for its glossy bright fls. The color varies in the shades of red. Var. **rùbrum** has bright red fls. Var. **kermesìnum** is crimson. Var. **coccíneum,** Hort., is a scarlet-fld. form.—In a warm, sunny place, the flowering flax makes a very satisfactory plant of long period of bloom. It is not adapted to cutting, since the fls. are not durable. Will not stand frost.

BB. *Bloom blue.*

2. **usitatíssimum,** Linn. Flax. Much cult. for linseed and for fiber, and running wild along railroads and in fields: 2–3 ft. high, very slender-branched, glabrous: lvs. small, linear or lanceolate, acute, alternate: fls. about ½in. across, light blue, soon withering: pod large, mostly exceeding the scarious-edged sepals, nearly or quite indehiscent, the septa not ciliate. *L.* **hùmile,** Mill., also cult. and sometimes escaped, is lower and has a dehiscent caps. with ciliate septa. It is probably only a form of the above, and it has run wild in this country.—Flax has been cult. from time immemorial, and it is unknown in an originally wild state. Some authorities consider it to be a modified form of *L. perenne;* others think it to be derived from *L. angustifolium,* Huds., an annual or perennial species with small fls., short linear lvs., and decumbent st., growing from England to W. Asia.

2180. Linum grandiflorum. (Natural size)

AA. *Plant perennial: fls. yellow, white, or blue.*

B. *Bloom yellow* (*L. trigynum, which may be sought here, will be found under the genus Reinwardtia*).

3. **flàvum,** Linn. Erect from a somewhat woody base, glabrous, 1–2 ft.: lvs. lanceolate or linear, alternate: fls. golden yellow, in a much-branching cyme, the showy petals much exceeding the glandular-ciliate sepals. Eu. B.M. 312.—A good half-hardy perennial, but not popularly known in this country.

4. **virginiànum,** Linn. (*Cathartolìnum virginiànum,* Reichb.). Perennial, producing suckers, 1–2 ft., glabrous, branched above: lvs. thin and deep green, elliptic-lanceolate to narrow-oblong or the lower spatulate, 1-nerved: fls. yellow, about ⅓in. broad, scattered; sepals ovate, short-pointed, entire or nearly so; styles distinct: caps. depressed-globose, 10-celled. Maine to Ga. and Ala.—Offered as a good garden perennial.

5. **arbòreum,** Linn. Small shrub, spreading: lvs. wedge-shaped, obtuse, recurved: fls. few and large, clear yellow, in close clusters; sepals acuminate. Crete. B.M. 234. Gn. 77, p. 435.

BB. *Bloom white.*

6. **monógynum,** Forst. Variable glabrous perennial 1–2 ft. high, sometimes woody at base, the sts. simple or branched, erect or spreading: lvs. many, scattered, 1 in. or less long, linear-oblong to linear-subulate, 1–3-nerved: fls. white, often 1 in. diam., in terminal corymbs; sepals acute, ovate to ovate-lanceolate; styles united at base: caps. broadly ovoid, large. New Zeal. B.M. 3574. J.H. III. 57:13.—An attractive species.

7. **salsoloìdes,** Lam. Perennial, evergreen, 1 ft., woody at base, the sts. branched and somewhat twisted: lvs. small, setaceous: fls. white with purple eye; sepals ovate, acuminate, with glandular hairs at middle. Mediterranean Alps. G.C. III. 54:42. G. 36:681 (var. *nanum*).—A showy species.

BBB. *Bloom blue* (*running into white varieties*).

8. **perénne,** Linn. Fig. 2181. Erect-growing and branchy, glabrous, 1–2½ ft. tall: lvs. linear and acute, alternate: fls. rather small, azure-blue (there is a white-fld. form; var. **âlbum,** Hort.), on the ends of slender pedicels, the styles and stamens of different lengths (fls. heterogonous) in different fls.: caps. ovoid, dehiscent, on inclined pedicels. Eu.—Worthy hardy perennial, summer-blooming, often flowering the first year from seed. *L. sibíricum,* DC., belongs with this species.

9. **Léwisii,** Pursh (*L. perénne* var. *Léwisii,* Eaton & Wright). Prairie Flax. The W. American representative of the above, and scarcely distinguishable from it except that the fls. are not heterogonous, pedicels more erect in fr.; calyx-nerves not evident: fls. 1½ in. across, clear sky-blue, very pretty. Wis., west and south.

10. **austrìacum,** Linn. (*L. perénne* var. *austrìacum,* Voss.). Lvs. linear, punctate: fls. rather small, violet-red or light blue: fruiting pedicels horizontal or reflexed. Austria.—Hardy N., growing 1–2 ft. high and blooming all summer.

11. **alpìnum,** Linn. (*L. perénne* var. *alpìnum,* Voss). Low, about 6 in., with erect shoots: lvs. small, crowded below, pellucid-dotted, linear-subulate: fls. few, large, blue; inner sepals obtuse, the outer ones somewhat acute. Eu.

12. **narbonnénse,** Linn. One to 2 ft. high, forming a spreading clump, glabrous and slightly glaucous, and very handsome for rockwork: lvs. linear-lanceolate, pointed, alternate: fls. 1½ in. across, on slender pedicels in loose panicles, azure-blue, with white eye and white stamens. Eu. G.C. III. 50:468. Gn. 52, p. 401. G. 26:460.—Blooms in late spring and early summer: a good hardy species.

2181. Linum perenne. (×½)

L. campanulàtum, Linn. Perennial yellow-fld. species from S. Eu., 1–1½ ft., glaucous: lvs. on st. oblanceolate, acuminate, alternate. L.B.C. 13:1254.—*L. Chamissònis*, Schiede (L. Macraei, B.M. 5474, not Benth.). Perennial, woody at base, with scarlet buds and yellow fls.: lvs. stiff, lanceolate, acuminate: sepals ovate, acuminate: 1 ft. Chile.—*L. pubéscens*, Soland. Perennial, with large pink fls. shaded with dark purple lines, the petals 3 times as long as calyx: lvs. oblong and obtuse to lanceolate and acute. Asia Minor.—*L. trígynum*, Roxbg.=Reinwardtia trigyna.

L. H. B.

LÍPARIS (Greek, *fat, shining*). *Orchidàceæ.* Erect little plants with stems in some species 1 foot high, bearing one or several leaves and a terminal raceme of small, rarely medium-sized flowers.

Herbs, terrestrial or epiphytic: sts. sometimes thickened at the base into a small pseudobulb, sheathed by scales: lvs. few, broad, contracted into sheathing petioles: fls. whitish, greenish yellow or purplish; sepals and petals nearly equal, linear, spreading; column long; lip nearly plane, often with 2 tubercles above the base.—A large genus, containing over 100 species, distributed over the warm and temperate regions of the entire earth. By some, the name Leptorchis is used for this genus, but Liparis is retained by the "nomina conservanda" of the Vienna Congress.

L. liliifolia should be planted in well-drained soil; a shady bank is preferable. *L. Lœselii* delights in a wet situation, just at the edge of the water.

liliifòlia, Rich. Twayblade. Plants 4–10 in. high: lvs. oval or ovate, 5 in. long: raceme with many purplish fls.; labellum large, wedge-obovate. Succeeds in well-drained soil on shady banks; woods and thickets, E. N. Amer. B.B. 1:476. A.G. 12:153 and 13:517.—Procurable from Dutch bulb-dealers and dealers in native plants.

Lœsélii, Rich. Plants 2–8 in. high: lvs. elliptic-lanceolate, 2–6 in. long: raceme with few greenish fls.; lip obovate pointed. In wet thickets, N. Amer. and Eu. B.B. 1:477. G.C. II. 21:144.

L. atropurpùrea, Lindl. Plants 1 ft. or more high: lvs. 2–4, nearly round, acuminate plicate, near together at the upper part of the st.: raceme many-fld.; fls. chocolate-purple; lip oblong, obtuse, recurved. June. Ceylon. B.M. 5529.—The most ornamental of the genus.—*L. Càillei*, Finet. Dwarf: racemes several-fld.; scape 4-winged: lvs. membranous, not plicate. French Guinea.—*L. laceràta*, Ridl. Racemes about 8 in. long; sepals and petals yellowish, oblong, obtuse; lip orange-red. Borneo.—*L. nàna*, Rolfe. Plant very small: fls. dark purple, remarkable in having a very broad, nearly straight column. Annam.—*L. rhodochìla*, Rolfe. Scape many-fld.; sepals and petals light green; lip reddish crimson. Java.—*L. tabulàris*, Rolfe. Raceme lax; fls. purple; dorsal sepal oblong-lanceolate, the lateral oblong; petals filiform; lip reniform, denticulate. Penang. B.M. 8195.—*L. tricallòsa*, Reichb. f. Raceme loosely many-fld., the rachis red; sepals strap-shaped, lemon-yellow; petals filiform, arched, red; lip nearly orbicular, golden yellow, red-striped. Malay Penin. B.M. 7804.—*L. Wárpuri*, Rolfe. Only a few inches high: scape 1- or 2-fld.; fls. light green, with dark green disk. Madagascar.

Heinrich Hasselbring.
George V. Nash.†

LÍPPIA (Dr. Auguste Lippi, French traveler, 1678–1703). Including *Aloýsia. Verbenàceæ.* Herbs and shrubs, grown for the ornamental bloom, and one as a ground-cover; the lemon verbena of florists is one of them.

Mostly shrubby, with opposite or 3-whorled (rarely alternate) lvs., which are entire, dentate or lobed: fls. small and often lantana-like, in heads or spikes, mostly white, rose or purplish; corolla 4-lobed, oblique or 2-lipped, the tube cylindrical and straight or curved, the lobes broad and usually retuse; calyx 2–4-toothed or -cleft, inclosing the dry fr. which becomes 2 separate nutlets: stamens 4, didynamous, attached at the middle of the corolla-tube, included or very nearly so; ovary 2-celled, each cell 1-ovuled.—Species about 125, nearly all in Trop. Amer., but 2 or 3 African and 1 or 2 widely dispersed in warm countries. The genus is botanically nearer Lantana than Verbena, although the common forms of all three genera are very unlike horticulturally. Some species of Lippia have their spikes crowded into dense heads, like Lantana. The drupe in Lippia is dry, but in Lantana it is often juicy, and in Lantana the calyx is more or less truncate and the corolla not bilabiate.

The one well-known cultivated lippia is lemon verbena (*L. citriodora*), an old-fashioned favorite, with delightfully fragrant foliage, a sprig of which was often included in mixed bouquets. It is a low-growing tender shrub, with long narrow pointed entire leaves, which are usually borne in threes. In summer, it bears minute flowers in a pyramidal panicle, composed of many-flowered spikes, which appear in groups of three at decreasing intervals along the main axis. In southern California it attains a large size.—Culture by William Scott: A florist should always have a few lemon verbenas. Save a dozen plants in spring, shift them on as required, and in the summer plunge the pots outside. At the approach of frost bring them into the greenhouse, stand them under the lightest and coolest bench, and give them water enough merely to keep the wood from shriveling. In early February shake the plants out of the pots, shorten the unripened and weak wood, repot in fresh soil, using 4-inch pots, and start the plants into fresh growth in a temperature of 55°. In a few weeks they will be covered with new growths suitable for cuttings. Cuttings root readily in about three weeks. The sand of the cutting-bench should be a little warmer than the air. Water the sand twice a day, and keep it well soaked. Never allow the cuttings to wilt from sunshine or dryness. Transfer the cuttings when rooted to 2-inch pots, and in April shift to 3-inch pots, plunging them in a mild hotbed, where by the middle of May, with one pinching, they will have become fine, bushy plants. They need frequent syringing to prevent attacks of red-spider.

In California, Arizona, Mexico, Australia, the plant known as *L. repens* (properly *L. canescens*) is now an important ground-cover or lawn plant. The many thousands of acres thus covered are said all to have come from plants secured in a twelve-ounce box from the Botanic Garden in Rome by F. Franceschi, of Santa Barbara, in 1898.—Culture by Franceschi: It thrives in any soil, no matter how poor, rapidly covering the ground with a very dense matting. It will smother all weeds in short time, and the more trodden upon the better it grows. It requires much less water than other lawn plants, and saves the trouble of mowing. It will stand severe heat and many degrees of cold, and can easily be established on sloping grounds. It will never become a pest difficult to eradicate, having no underground runners. Have the ground well worked and pulverized, leveled and rolled, if possible. No manure is recommended. It seeds very sparingly or not at all. The best and quickest way to propagate it is by planting small sods (of 2 square inches) at a distance of 1, 2, or more feet apart, as one may prefer. The closer planted, the sooner the ground will be carpeted. Each small sod contains many joints, and from each joint runners and roots soon appear that will branch in every direction and will anchor it in the ground, rooting again as they run. Press and firm the sods in the ground, and give sufficient water to start them to grow. Occasional rolling will be of advantage. Frequent walking over it will have the same effect. If the tiny lilac flowers (much sought by the bees) are not desired, they can easily be removed with an ordinary lawn-mower. During the dry season, water must be given, with a lawn sprinkler or otherwise, at intervals as the local conditions suggest.

A. *Fls. in slender naked spikes.*

citriodòra, Kunth (*Aloýsia citriodòra*, Ort.). Lemon Verbena. Small shrub, glabrous, the branchlets striate and more or less scabrous: lvs. in whorls of 3 or 4, lanceolate, short-stalked, glabrous, densely covered beneath with glandular dots, entire or toothed at the middle, lemon-scented: spikes whorled and axillary or collected in terminal panicles, which may be 3 in. long and wide: fls. white, small, in summer and autumn. Uruguay, Argentina, Chile. B.M. 367 (as *Verbena triphylla*). Sometimes grown as standard and tree-like. G.C. II. 11:301.

ligústrina, Brit. (*L. lycioìdes,* Steud. *Verbèna ligustrìna,* Lag.). Tall shrub, often spiny, the branches more or less pubescent: lvs. small, coriaceous, opposite, elliptic-oblong or lance-oblong, attenuated to petiole, obtuse or acute, the margin somewhat revolute, entire or serrate at middle: racemes somewhat crowded, canescent, 2–3 in. long; fls. small, white, vanilla-scented; calyx campanulate, 5-costate, hirsute, with subulate teeth; corolla exceeding calyx, the throat villous. Mex. to Argentina.—Offered in S. Calif., where it is said to withstand drought exceedingly well.

chamædrifòlia, Linn. Shrubby, half climbing, branches 4-angled and pubescent: lvs. aromatic, opposite, very short-petioled, ovate, acute, coarsely serrate, margin revolute, shining above and more or less tomentose beneath: racemes 3–5 in. long, paniculate; fls. small, rosy lilac; calyx ovate, hirsute, the short teeth ovate-acuminate. Brazil, Argentina.—Offered in S. Calif.

urticoìdes, Steud. Tall shrub, with strict terete glabrous branches: lvs. dark green, rough, not aromatic, 3 in. long, opposite, ovate or oblong, attenuated into the petiole, acute, crenate-serrate: racemes paniculate; fls. white, vanilla-scented; calyx tubular, pilose below, partially 4-toothed, the teeth subulate-cuspidate. Peru, Brazil, etc.—Offered in S. Calif.

AA. *Fls. capitate or in short dense spikes, with broad bracts.*

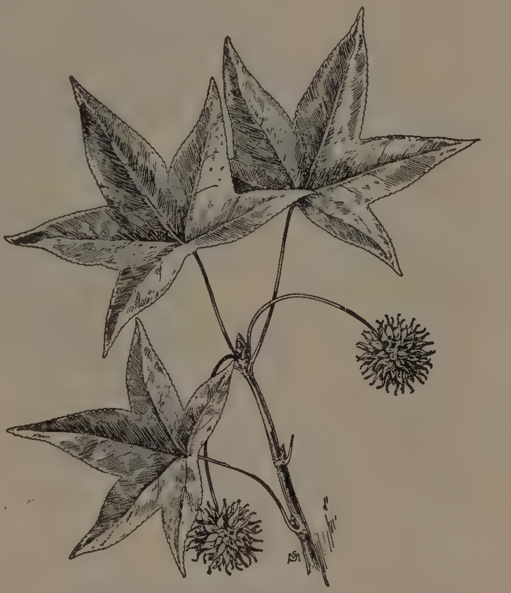
canéscens, Kunth (*L. rèpens,* Hort., not Spreng.). St. somewhat woody at the base and rooting, widely spreading, canescent: lvs. small, from spatulate to oblong and lanceolate, attenuate to petiole, acute, dentate toward apex: heads ovoid or subcylindrical; the bracts herbaceous, obovate-cuneate, acuminate, narrowly membranous-margined, imbricated; corolla conspicuously larger than in related species, rosy, with a yellow throat; calyx short 2-toothed, with villous keels; bracts of fl.-head shorter than the corolla-tube, with villous margins. S. Amer., in dry, grassy places.—This plant, under the name of *L. repens,* is exceedingly useful in Calif. as a ground-cover, especially to persons who do not care to go to the expense of keeping up a grass-lawn. The tops sometimes freeze in the region of San Francisco, but the plants come on well in spring. By keeping the area mown, the weeds are not very troublesome.

nodiflòra, Michx. (*Verbèna nodiflòra,* Linn. *Zapània nodiflòra,* Lam. *Phỳla nodiflòra,* Greene). Sometimes described as annual, but probably perennial, extensively creeping and rooting but with ascending branches, greenish or grayish: lvs. opposite, cuneate-spatulate to oblanceolate, nearly or quite sessile, tapering to a long entire base, serrate above the middle: heads ovoid and becoming nearly cylindrical, on filiform peduncles that exceed the lvs., the bracts obovate or irregularly cuneate, acuminate and sometimes mucronate; fls. rose-purple to nearly white, the corolla short; calyx thin in texture, equaling corolla, unevenly cleft on the two sides, the teeth lanceolate; bracts of fl.-head about as long as corolla-tube, with glabrous or nearly glabrous hyaline margins. Sandy soil, Ga., south (in the tropics widely distributed); in Calif. prominent on river banks, and, according to Jepson, esteemed for holding levees against erosion. L. H. B.

LIQUIDÁMBAR (from Latin *liquidus,* fluid, and the Arabic *ambar,* amber; in allusion to the fragrant juice which exudes from the tree). *Hamamelidàceæ.* Ornamental trees grown chiefly for their handsome foliage assuming crimson tints in autumn.

Deciduous: lvs. alternate, slender-petioled, palmately 3–7-lobed, serrate, with small stipules: fls. apetalous, usually monœcious, in globular heads; staminate fls. without perianth, intermixed with small scales, in heads forming a terminal raceme; pistillate fls. in slender-peduncled globular heads consisting of more or less cohering 2-celled and 2-beaked ovaries subtended by minute scales in place of calyx-lobes: fruiting head globose, spiny from the persistent styles, consisting of dehiscent caps., each with 1 or 2 winged seeds.—About 4 species in N. and Cent. Amer. and in W. and E. Asia. *L. orientalis* yields the liquid storax; the resin of *L. Styraciflua* is used in the preparation of chewing-gum.

Only *L. Styraciflua* is well known in cultivation; it is a beautiful pyramidal tree of very symmetrical habit with maple-like lustrous leaves assuming a deep crimson color in autumn; in winter it is conspicuous from its usually corky branches, the persistent pendulous fruit-heads and the deeply furrowed bark. It is hardy as far north as Massachusetts; it is of moderate growth and prefers moist situations. It is free from insects and diseases and is said to withstand salt air. It requires close pruning when transplanted. Propagation is by seeds which should be stratified as soon as ripe; many of them do not germinate until the second year.



2182. Liquidambar Styraciflua. (×⅓)

Styracíflua, Linn. Sweet Gum. Bilsted. Alligator Tree. Fig. 2182. Tree, 60–140 ft. high: lvs. 5–7-lobed, with acuminate, finely serrate lobes, lustrous and dark green above, paler below and glabrous except large tufts of pale rufous hairs in the axils of the principal veins, 3-7 in. across; petioles 5–6 in. long: fr. 1–1½ in. across. March–May. Conn. and S. N. Y to Fla., Ill., Mc and Mex. S.S. 5:199. G.F. 2:235. P.G. 3:111. G.C. II. 14:633. Mn. 4:117. Gn. 24, pp. 166, 167; 38, p. 208. F.S.R. 3, p. 85. F.E. 18, p. 90.

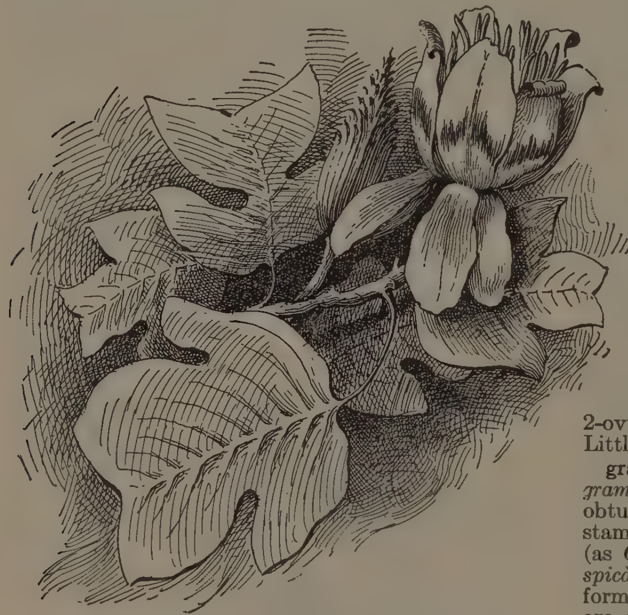
L. formosàna, Hance. Tree, to 120 ft.: lvs. usually 3-lobed, pubescent on young plants, glabrous on older trees and only slightly hairy in the axils; scales subtending the ovary subulate, becoming spiny in fr. S.E. to Cent. China. H.I. 11:1020. Var. *montícola,* Rehd. & Wilson. Lvs. always glabrous. Hardier than the type. Cent. China.—*L. orientàlis,* Mill. (L. imberbe, Ait.). Lvs. usually 5-lobed, the lobes usually with 2–4 small lobes, quite glabrous, smaller than in L. Styraciflua. W. Asia. H.I. 11:1019. F.S.R. 3, p. 87. Somewhat less hardy than L. Styraciflua.

Alfred Rehder.

LIQUORICE: *Glycyrrhiza.*

LIRIODÉNDRON (*lirion*, lily, and *dendron*, tree; referring to the shape of the flowers). *Magnoliàceæ.* Tulip Tree. Whitewood. Yellow Poplar. Ornamental trees grown for their handsome foliage and large tulip-like flowers.

Deciduous: lvs. alternate, long-petioled, 2–6-lobed, with conspicuous deciduous stipules cohering when young and inclosing the next lf.: fls. terminal, solitary, with 3 spreading sepals and 6 erect, broadly ovate petals; stamens numerous, with long and linear anthers; pistils numerous, forming a narrow column, developing into a light brown cone; at maturity the carpels, each consisting of a long, narrow wing with a 1–2-seeded nutlet at the base, separate from the slender spindle.—Two species in N. Amer. and China.



2183. Tulip tree.—Liriodendron Tulipifera. (×½)

Only the native species, one of the nobiest trees of the American forest, is well known in cultivation. It is a hardy beautiful tree of pyramidal habit, well adapted for park-planting and for avenues, with handsome, clean foliage of unusual shape and of rather light bluish green color, rarely attacked by insects or fungi, assuming in fall a brilliant yellow color; the tulip-like flowers, though of not very showy color are conspicuous by their size and shape. The tulip tree is also an important forest tree, and the soft, fine-grained, light yellow wood is much used in carpentry for furniture, boat-building and the manufacture of small articles; it does not split easily but is readily worked and bent to any required shape. The inner bark is said to have medical properties. The tulip tree grows best in deep, rich and somewhat moist soil. Transplanting is not easy; it is best done in spring, just before the tree starts into new growth. Propagate by seeds sown in fall or stratified and sown in spring; varieties are usually grafted or budded on seedling stock, rarely propagated by layers. The seeds are sometimes hollow, especially those grown along the eastern limit of the species.

Tulipífera, Linn. Fig. 2183. Tall tree, to 150, rarely to 190 ft., with a trunk to 10 ft. diam., often destitute of branches for a considerable height, glabrous: lvs. about as broad as long, with 2 lobes at the truncate and notched apex and 2–4 lobes at the base, bluish green above, pale or glaucous beneath, 5–6 in. long: fls. greenish yellow, marked orange within at the base. 1½–2 in. long; petals ovate or oval; fertile carpels acute. May, June. Mass. to Wis., south to Fla. and Miss. S.S. 1:13. Em. 2:605. B.M. 275. Gng. 7:259. A.G. 1892:485. Mn. 2, p. 4; 6, p. 145. Gn. 34, p. 42; 76, p. 646. F.S.R. 2, pp. 5, 7; 3, p. 203. G.C. III. 55:255. V. 20:86. Var. **pyramidàle,** Lav. (var. *fastigiàtum*, Hort.). With upright branches, forming a narrow pyramid. Var. **integrifòlium,** Kirchn. Lvs. rounded at the base without lobes. Var. **obtusílobum,** Pursh. Lvs. with only 1 rounded lobe on each side of the base. Var. **contórtum,** Goeschke. Lvs. with 2 lobes on each side, twisted so that the upper lobes often form a right angle to the lower ones. There are also several vars. with variegated lvs., of which var. **aùreo-marginàtum,** Hort. (var. *panaché*, Hort.), with lvs. edged yellow, is one of the best. F.S. 19:2025; 20:2081.—In the Middle West, liriodendron is universally known as whitewood. To lumbermen in the East it is known as poplar and tulip poplar.

L. chinénse, Sarg. (L. Tulipifera var. chinense, Hemsl.). Tree, to 50 ft.: lvs. with 4 acute or acuminate lobes, rounded or slightly cordate at the base, 5–6 in. long: fls. 1–1½ in. long: cone slenderer, the fertile carpels obtuse or obtusish at the apex. Cent. China. G.C. III. 34:370; 44:429. S.T.S. 1:52. H.I. 28:2785.—Seems somewhat tenderer than the native species.

Alfred Rehder.

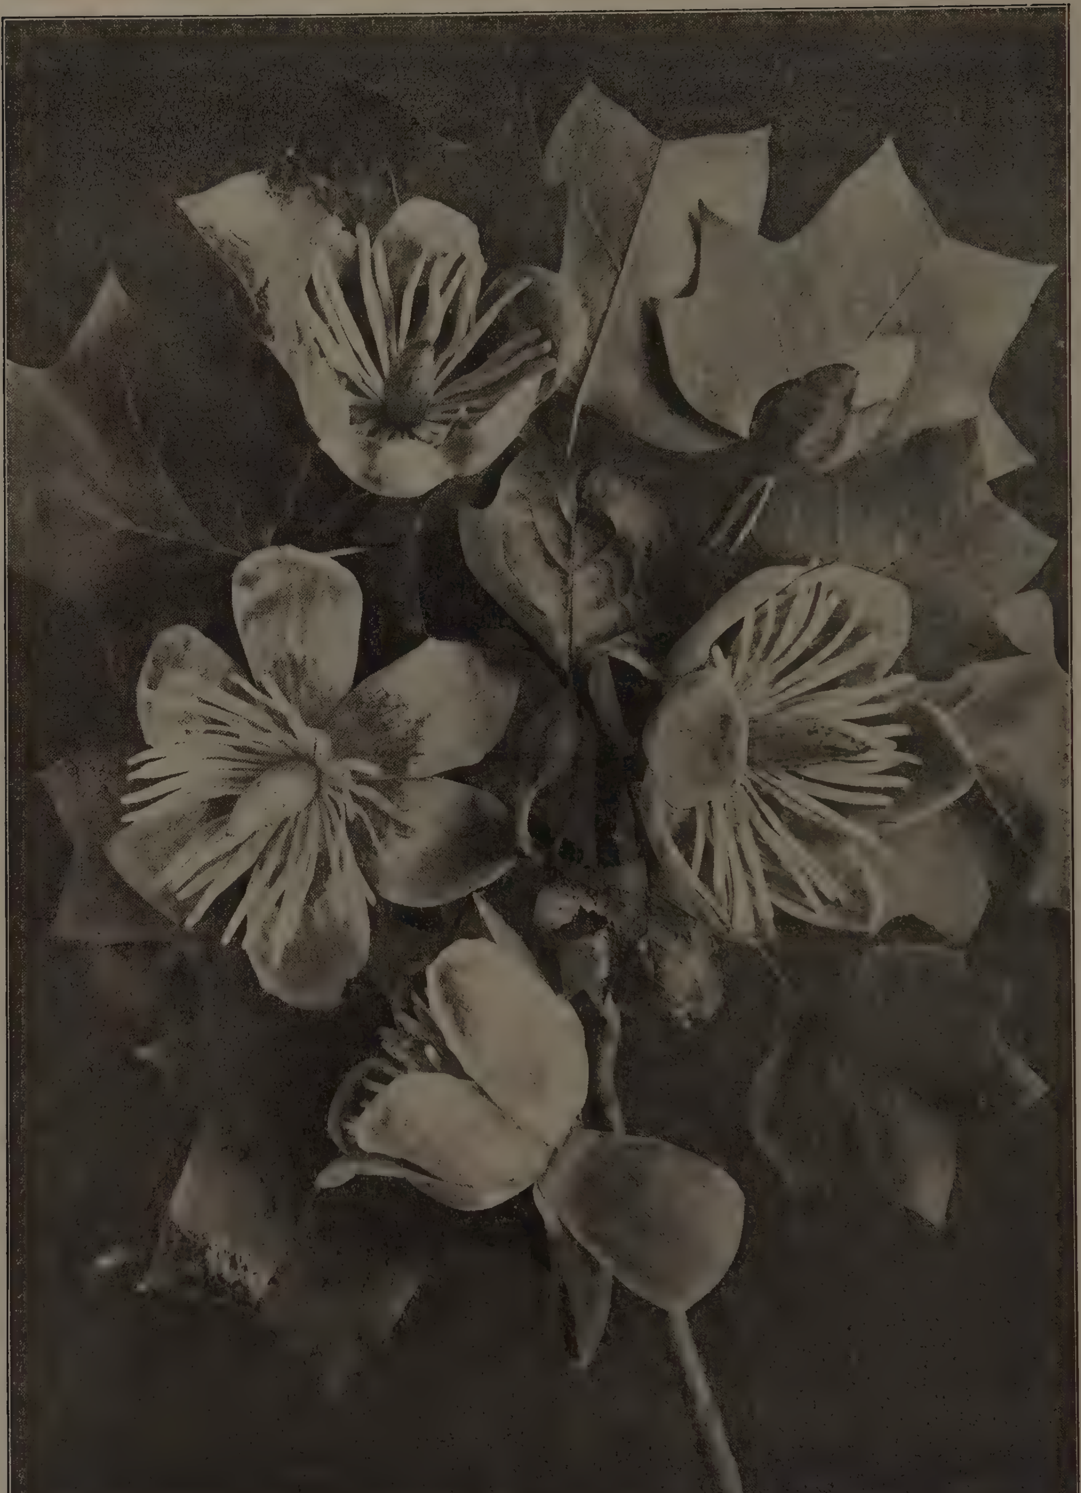
LÌRIOPE (named after the nymph Liriope). *Liliàceæ.* A tender violet-flowered cultivated plant from China and Japan.

Plants of somewhat doubtful affinity, having been referred to different families: rhizome short and thick, often stoloniferous: st. very short, the lvs. narrow and crowded, the fls. on simple scapes, small, violet or whitish; segms. distinct; stamens 6, hypogynous; ovary 3-celled, each cell 2-ovuled.—Species about 3, China, Japan, Philippines. Little cult.

graminifòlia, Baker (*L. spicàta*, Lour. *Dracæna graminifòlia*, Linn.). Lvs. all radical, linear-lanceolate, obtuse, 3-nerved, with a few brown scales at the base: stamens 6; style columnar; ovary 3-celled. B.R. 593, (as *Ophiopogon spicatus*). Var. **densiflòra,** Hort. (*L. spicàta* var. *densiflòra*, Wright) is presumably the best form. B.M. 5348 (as *Ophiopogon spicatus*). There are several forms of this species, as: Var. **mìnor** (*L. spicàtus* var. *mìnor*, Wright). L.B.C. 7:694 (as *Ophiopogon spicatus*); var. **koreàna** (Wright); var. **intermèdia** (Maxim.).—*L. graminifolia* should perhaps be grown in the greenhouse. It is 1 ft. or more high with grass-like foliage and 1 or 2 scapes overtopping the lvs., which bear from July to Sept. as many as 90 violet-colored fls. in a spike-like raceme 6–12 in. long and 1 in. wide. The fls. are less than ½in. across, 6-parted and arranged in groups of 3–5 along the raceme. They vary from dark purple through violet to whitish. The deepest color is the finest, and is set off by the yellow anthers.

Wilhelm Miller.
L. H. B.†

LISIÁNTHUS (Greek compound). *Gentianàceæ.* About 10 species in the W. Indies and Cent. Amer., herbs or shrubs with mostly rather large yellow-green, brown-black or rarely white fls. in cymose clusters, and opposite lvs. None of the species seems to be in the trade, although *L. Russelliànus*, Hook. (*L. erythropénsis*, Hort.), is recorded as a cult. plant in garden literature; this plant is **Eùstoma Russelliànum,** Griseb., growing on plains Neb. to La. and Mex. Glaucous: st. simple, or with a few opposite branches: lvs. opposite, connate, ovate or ovate-oblong, 3–5-nerved: fls. panicled, as large as a tulip; lobes obovate, spreading: stigma of 2 very large, green, velvety, spreading plates: pod oblong; seeds minute, pale brown. B.M. 3626. G.C. III. 4:240. R.H. 1863:51; 1881, p. 189. G.M. 49:479. Gn. 70, p. 77. G. 25:292. G.W. 11, p. 138. H.F. II. 4:240. It is a tender annual and grows 1½



LXVI. The tulip tree.—Liriodendron Tulipifera.

ft. high, producing its 5-lobed, purple, dark-eyed fls. in summer and fall. Under favorable conditions the fls. are 4 in. across, as many as 10 or 11 on a plant, and individual blossoms have been known to last three weeks. According to F. L. Harris, in the Old World it is usually treated as a cool greenhouse subject, being sown in early spring for summer and autumn bloom. The seed should be sown carefully, and at every stage of the plant's growth over-watering should be guarded against. The seedlings are very likely to damp-off. When they are ready for transplanting from the seed-beds, use small pots. When larger plants are needed, place them in a light, airy place and give generous bottom heat. For soil, use good loam, sand and well-rotted manure. Wilhelm Miller.

LISSOCHÌLUS (Greek, *smooth lip*). *Orchidàceæ.* Terrestrial herbs, some of which are very handsome, but they seem to be little cultivated in America, only a single species being advertised here.

The plants are distinguished from their near allies by the dissimilarity of the sepals and petals, the latter being much larger and wider and usually of a different color: lvs. plicate and prominently veined, long and narrow: sts. very short, leafy, finally thickened into pseudobulbs: raceme simple; scape long, stout, sheathed but leafless, growing beside the pseudobulb; labellum spurred or saccate, joined to the base of the column.—About 30 species dispersed in Trop. and S. Afr.

The plants may be grown in a compost of fibrous loam, leaf-mold and sand. During the growing season they require plenty of water, but during three months of winter they should be allowed to rest and be kept dry.

Krébsii, A. Rich. Lvs. in tufts on the young sts. elliptic-lanceolate, 8–12 in. long: scape 2–3 ft. high; raceme 12–18 in. long, with 20–30 fls.; sepals linear-oblong, bent back, green, with dull purple blotches; petals much larger, golden yellow; lip yellow, pendulous, saccate between the small, rounded lateral lobes; middle lobe orbicular, notched in front. Flowers from May to Oct., the fls. remaining a long time. Natal. B.M. 5861.

L. Ándersonii, Rolfe. Racemes loose, 4–8-fld.; sepals and petals pale greenish or sulfur-yellow; lip white. Trop. Afr.—*L. gigantèus*, Welw. & Reichb. f. A gigantic orchid whose lvs. are said to grow to a length of 8 ft., with fl.-spikes twice as high: sepals linear, curled backward; petals oblong-quadrate, 1½ in. across, pinkish rose; labellum 3 in. long, with a long spur; middle lobe trowel-shaped, purple, striped with darker lines. Congo. G.C. III. 3:617. S.H. 2:355. I.H. 35:53. J.H. III. 55:52.—*L. Grántii*, Reichb. f. Raceme about 6-fld.; sepals brownish green; petals bright yellow behind, paler in front; lip light yellow. E. Afr.—*L. Hórsfallii*, Batem. A robust plant, with plicate lvs. 2–3 ft. long and 5–6 in. broad, sharp-pointed: fl.-stalk twice the length of the lvs., with many large fls. 3 in. diam.; sepals reflexed, rich purple-brown on the upper side; petals much larger, almost square, white, suffused with rose. B.M. 5486. G.C. III. 39:200. G.M. 49:193. C.O. 1. Handsomer than the first.—*L. Mahònii*, Rolfe. Raceme stout, many fld.; fls. large; sepals reflexed, green, suffused and veined with brown; petals rose-lilac; lip 3-lobed, the lateral erect lobes green, crenulate, brown-nerved, the front lobe spreading, retuse crenulate, the front purple, darker nerved, green at base; keels denticulate, undulate, greenish. Uganda. B.M. 8047.—*L. purpuràtus*, Lindl. Sepals and petals rose-pink, narrowly oblong; middle lobe of lip purple, ovate-oblong. Trop. Afr. B.M. 7921.—*L. ròseus*, Lindl. Lvs. broad and stiff: st. 3–4 ft. high: sepals brown; petals and labellum fine rose-colored. B.R. 30:12. Also a showy plant.—*L. speciòsus*, R. Br. Pseudobulbs nearly underground: lvs. dark green, ensiform: scape 2–4 ft. high, with fragrant fls. 2 in. across; sepals small, green, reflexed; petals large, yellow; lip mostly yellow, apparently on the upper side, due to the inversion of the fls. June, July. Cape. B.R. 573 (erroneously numbered 578). P.M. 4:25.—*L. stylìtes*, Reichb. f. Fls. purple; sepals reflexed, pale green, tinged lilac at base; petals nearly erect, pale purple, nearly orbicular; lip pandurate, pale purple; base widely pouched, white outside, pale green inside and brown-dotted. Trop. Afr. B.M. 8397.—*L. ugándæ*, Rolfe. Fls. numerous, yellow, marked with purple-brown at apex of sepals and petals; lip with front lobe oblong-orbicular, reflexed. Uganda. B.M. 8044.

Heinrich Hasselbring.
George V. Nash.†

LISTÈRA (after Martin Lister, 1638(?)–1712). *Orchidàceæ.* Small orchids, sometimes transferred to cultivated areas.

Small, slender, erect herbs, with fibrous or sometimes fleshy roots, bearing a pair of opposite green lvs. near the middle, and 1 or 2 scales near the base of the st.: fls. small, spurless, in a terminal raceme; sepals and petals similar, spreading or reflexed; labellum rather longer, narrow, entire or 2-lobed.—About 10 species, natives of the North Temperate Zone.

convallarioìdes, Torr. St. 4–10 in. high, with smooth, round-oval, obtuse, cuspidate lvs.: raceme 2–3 in. long, bearing 3–12 greenish yellow fls. June–Aug. In woods, Nova Scotia to Alaska and Calif.; south to N. C. in the mountains. B.B. 1:473.

cordàta, R. Br. Very slender, 3–10 in. high: lvs. cordate-ovate, mucronate: raceme 1–2 in. long, with 4–20 minute purplish fls. June–Aug. In moist woods, Nova Scotia to Alaska and Ore., south to N. J.; Eu. B.B. 1:473. Heinrich Hasselbring.

LISTRÓSTACHYS (Greek, *shovel* or *hoe*, and *spike*). *Orchidàceæ.* Orchids with the habit of Angræcum.

Racemes many-fld.; sepals and petals alike, spreading; lip adnate to the foot of the column, with a long thin or reflexed spur; column bent back against the dorsal sepal; pollinia 2, upon divided stalks.—About 60 species, in Trop. Afr.

pertùsa, Reichb. f. (*Angræcum pertùsum*, Lindl. *A. Pescatoreànum*, Lindl.). Sts. up to 1 ft. tall: lvs. narrowly strap-shaped, obliquely 2-lobed: fls. covering peduncle nearly to the base, about ½in. across, white, on the upper side; sepals and petals ovate; lip obovate-spatulate; spur slender, greenish. Bourbon. B.M. 4782.

L. bìdens, Rolfe. Free-flowering epiphytal orchid from W. Trop. Afr.: sts. elongated, many-lvd.: lvs. thick, ovate-oblong, obliquely 2-lobed: fls. fragrant, many, in slender hanging racemes, white or pinkish, the spur as long as the lip. B.M. 8014.—*L. bracteòsa*, Rolfe. St. very short: racemes axillary, few-fld.; fls. pale yellowish green, fleshy. Mauritius.—*L. caudàta*, Reichb. f. (Angræcum caudatum, Lindl.). Racemes zigzag, 5- or more-fld.: fls. distant, about 3 in. across; sepals and petals linear-lanceolate, olive-green, flushed with pale brown; lip clawed, obcordate-cuneate; spur pale brown, 8–9 in. long. Sierra Leone. B.R. 1844. O.R. 20:297. B.M. 4370.—*L. Chailluàna*, Reichb. f. (Angræcum Chailluanum, Hook. f.). Lvs. up to 8 in. long, 1½ in. broad: racemes 6–10-fld.; fls. milk-white; spur slender, flexuous, greenish. W. Afr. B.M. 5589. J.H. III. 43:579. G.C. III. 31: suppl. March 22.—*L. dactylóceras*, Reichb. f. About 3 in. high: lvs. very fleshy, sword-shaped: fls. white. W. Trop. Afr.—*L. fimbriàta*, Rolfe. Fls. translucent white, with slight greenish tinge; spur long and slender. Uganda.—*L. forsipàta*, Kränzl. Plant small: fls. pellucid, white. Trop Afr.—*L. hamàta*, Rolfe. Remarkable for having all the long spurs hooked at the tip: fls. white, with green spur. W. Trop. Afr. B.M. 8074.—*L. imbricàta*, Rolfe. Plant very small: spike about 7-fld.; fls. white, small. Trop. Afr.—*L. Kindtiàna*, Wildem. Dwarf: racemes short, dense; fls. yellow, star-shaped. Congo.—*L. Mónteiræ*, Reichb. f. (Angræcum antennatum, Kränzl.). Robust epiphyte from W. Trop. Afr., sometimes met with in cult.: 1–2 ft., bearing roots toward the base: lvs. oblong or obovate oblong, obliquely bilobed: racemes erect, many-fld., 6–12 in. long; fls. yellowish white, the upper part of spur ochreous and the base light green. B.M. 8026.—*L. pellùcida*, Reichb. f. (Angræcum pellucidum, Lindl.). Racemes pendulous, many-fld.; fls. semi-transparent, spiral, yellowish white; lip cordate, truncate at apex, fimbriate; spur short. Sierra Leone. G.C. III. 49:18. C.O. 1. R.B. 32, p. 38.—*L. vandæfórmis*, Kränzl. Plant very large: racemes nodding, many-fld.; fls. yellow. W. Trop. Afr. G.W. 13, p. 54.—*L. Whỳtei*, Rolfe. Racemes several-fld.; fls. small, sweet-scented, white, wax-like, with pointed brown-tipped spurs. Uganda. George V. Nash.

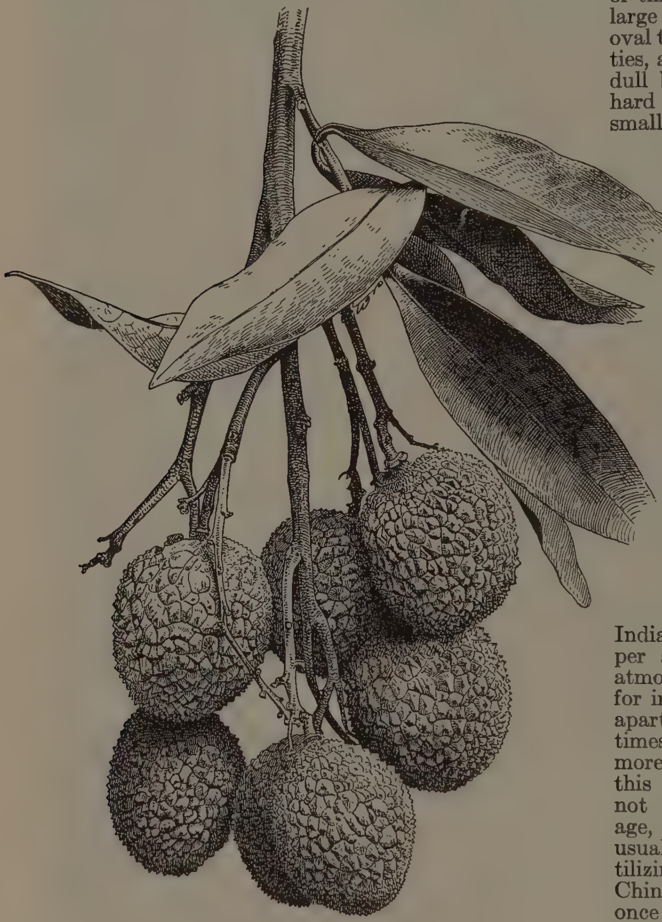
LÌTCHI (Chinese name). *Sapindàceæ.* One species in China, and cultivated elsewhere for its edible fruit.

By some botanists included in Nephelium, but the definition is probably clearer if Litchi and Euphoria are kept distinct, both of which differ from Nephelium in having the seed-covering or arillus free from the seed rather than grown to it.

chinénsis, Sonn. (*Scytàlia chinénsis*, Gaertn. *Dimocárpus Lìchi*, Lour. *Nephèlium Lìtchi*, Camb.). Litchi or Leechee. Fig. 2184. Lfts. 2–4 pairs, elliptic-oblong to lanceolate, glabrous, lustrous above, glaucescent beneath. China. A.G. 12:269.—Not to be confounded with the longyen (see *Euphoria*) or the rambutan (see *Nephelium*). L. H. B.

Culture of the litchi

Of the numerous fruits cultivated in south China. the litchi (*Litchi chinensis*) is one of the most highly esteemed, both by natives and Europeans. It is considered indigenous to the region, but has been in cultivation since a remote day, and lends itself to a wider variety of uses than many other tropical fruits. As a dried fruit it is well known, and is shipped to the United States and other occidental countries, while a considerable quantity is preserved in syrup and exported. Like most other fruits, however, it is considered most delicious when fresh.



2184. Litchi. (×⅔)

Its cultivation is not limited to south China and the adjoining regions. In parts of India it is very well known, especially in the section north of Calcutta, while it is also grown to a limited extent in northeastern Australia, Formosa, southern Japan, Hawaii, the West Indies, Brazil, and other regions. It is said to have been introduced to Florida in 1886, but, so far as known, has not yet fruited in that state, although in certain sections the climate and soil seem well adapted to its culture. It bloomed at Tampa in 1914 and 1915, but the trees were young and failed to carry any of their fruit to maturity. In California it has been grown successfully only in the most protected locations. The first fruits ripened in that state were produced at Santa Barbara in 1914. The litchi is quite susceptible to frost when young, but mature trees will withstand several degrees of freezing without permanent injury.

The litchi is a small to medium-sized tree, usually spreading in habit, with a dense head of bright green foliage. The leaves are compound, with two or three pairs of elliptical to lanceolate leaflets 2 to 3 inches in length. In India it is said to flower in February, in China during April, ripening its fruits about the first of May in the one case and during July in the other. The flowers are small and inconspicuous, but are produced in great abundance in terminal panicles.

The fruits, which are borne in loose clusters of two or three to twenty or even more, have been likened to large strawberries in appearance. In shape they are oval to ovate, in diameter 1½ inches in the better varieties, and in color deep rose when fully ripe, changing to dull brown as the fruit dries. The outer covering is hard and brittle, rough on the surface and divided into small scale-like areas, from which short conical protuberances usually arise. The seed is small and shrivelled in the grafted varieties, but in seedlings is as large as a good-sized castor bean; surrounding it, and separating from it readily, is the edible part, in reality the aril, which is translucent, whitish, juicy, and of firm texture. In flavor it is subacid, strongly suggestive of the Royal Ann cherry, especially when cooked. Firminger says it is "as delicious, perhaps, as that of any fruit in existence." The fruit is dried just as it comes from the tree, the aril shrinking away from the thin outer shell and remaining as a rather tough layer around the seed. In this form the litchi is occasionally seen on fruit-stands of American cities; the flavor bears little resemblance to that of the fresh fruit, having been likened to that of raisins.

In China the litchi is said to succeed best when planted on deep rich soil near the bank of an irrigating-canal. A soil rich in humus is by far the best, and there should be an abundance of water for irrigating purposes. From the fact that the tree does well in parts of northern India where the rainfall is not more than 40 inches per annum, it does not appear that a very humid atmosphere is necessary, provided there is ample water for irrigation. The trees should be set about 25 feet apart, and require very little pruning. It is sometimes necessary to thin the young fruits, leaving no more in a cluster than the tree can properly mature; this results in larger and finer fruit. Seedlings do not come into bearing until seven to nine years of age, but trees propagated by layering or grafting usually commence to bear at three to five years. Fertilizing is said to be extensively practised by the Chinese, an application of liquid manure being given once in every three or four months.

The gootee method of propagation, as it is known in the Orient, is the method most commonly employed by the Chinese, and is used in India as well. A healthy, well-matured branch is chosen, and a narrow ring of bark removed just below a leaf-bud or node. Around this is formed a ball of clay soil, with an outer covering of coconut fiber, tow, or moss, to hold it together. A little above the ball a good-sized flower-pot or earthen vessel is suspended, and a piece of soft rope is inserted through the small hole in the bottom. The rope should fit the hole snugly, and is knotted on the inside; it is then carried to the gootee, and wound around the ball several times. The water trickles from the pot, which should be filled every day or two, and after running slowly down the rope is distributed over the gootee, keeping it uniformly moist. The gootee is made in spring, from February to April, depending upon climatic conditions, and at least three or four months are required for roots to form. When the ball is filled with roots and they begin to show on the surface, the branch is severed from the tree and planted in its permanent location in the orchard.

In India, layering is often practised, the outer ends of branches being laid across flats of soil suspended upon a light framework of poles. After a notch is made in the under side of the branch, it is covered with soil for a distance of several inches, and kept moist by frequent waterings. Inarching is also practised, the method being the same as for the mango. Seedling litchis are generally used for stocks. The litchi can be grafted on its near relative the longan (*Euphoria Longana*), but it takes a longer time to effect a union, and it is believed that the tree grows more slowly than when on litchi stock.

The amount of variation among seedling litchis is considerable; hence the best varieties can be propagated only by some vegetative means, though seedlings are often grown. Grafting and layering have not only the advantage of reproducing a known variety, but trees so propagated come into bearing several years earlier than seedlings. Seeds should be sown as soon as possible after their removal from the fruit, as they do not long retain their vitality.

The Chinese cultivate several named varieties, and there are at least eight known in India, of which the best are said to be McLean's and Bedana ("seedless"), the latter having a very small stone which is usually sterile. Firminger mentions one variety in India which is green in color and of a distinct and very sweet flavor.

F. W. Popenoe.

LITHOSPÉRMUM (Greek, *stone seed;* the seeds like little stones). *Boragináceæ.* Gromwell. Puccoon. Low-growing hardy mostly herbaceous perennials of minor importance, some of them attractive as alpines and in rock-gardens.

Lithospermum has fifty species in extra-tropical regions around the globe, mostly in the northern hemisphere: herbs or subshrubs, rough, silky, or bristly: lvs. alternate, sessile and entire: fls. white, yellow, bluish or violet, in leafy often curved racemes or spikes, sometimes dimorphous as to stamens and style; calyx 5-parted; corolla funnel- or salver-shaped, 5-lobed, the tube cylindrical and straight, the throat naked or crested; stamens 5, fixed to the tube; ovary 4-lobed, with a slender style, stigma usually capitate or 2-lobed: plants mostly with red roots. The genus is closely allied to Moltkia, which see.

In cultivation, the best known is *L. fruticosum,* a rock-garden trailer, which bears numerous leafy spikes of blue flowers, each about ½ inch across, from early summer to autumn. *L. purpureo-cæruleum* is also an old garden plant. The common gromwell, *L. officinale,* is rarely cultivated as a medicinal herb. Others are procurable from dealers in native plants. Seeds of the gromwell and the western species are procurable, and plants of the other kinds from dealers in rock-garden plants. *L. fruticosum* is said to be propagated only by cuttings of the previous year's wood; *L. multiflorum* by cuttings of young shoots. The kinds with red roots yield a dye. *L. arvense* is an annual or biennial introduced weed; but most of the species (and those cultivated) are perennial. The best known garden kinds are European, but the American species are deserving of greater attention.

INDEX.

albicans, 7.
angustifolium, 6.
canescens, 4.
fruticosum, 8.
Gastonii, 10.
Gmelinii, 5.
hirtum, 5.
linearifolium, 6.
multiflorum, 3.
officinale, 1.
pilosum, 2.
prostratum, 8.
purpureo-cæruleum, 9.
Zollingeri, 11.

a. *Color of fls. dull white.*

1. **officinàle,** Linn. Gromwell. Much branched, 2–3 ft. high: lvs. lanceolate or ovate-lanceolate, 2 in. or less long: infl. sparse; throat of corolla crested with appendages; fls. dull white, small; tube about as long as the calyx. Along N. E. roadsides, naturalized from Eu.

aa. *Color of fls. yellow or orange.*

b. *Corolla-tube scarcely, if any, exceeding the calyx.*

2. **pilòsum,** Nutt. Mostly unbranched, 1 ft. high: lvs. linear and linear-lanceolate, 2–4 in. long: fls. dull greenish yellow, crowded in a leafy thyrse; throat of corolla nearly devoid of appendages. W. N. Amer.

bb. *Corolla-tube much longer than the calyx: roots red, long and deep: fls. large, showy.* (Puccoons.)

c. *Floral lvs. reduced to bracts no longer than the calyx.*

3. **multiflòrum,** Torr. Height 1–2 ft., often paniculate-branched at summit: lvs. linear to linear-lanceolate: fls. numerous, short-pedicelled and sometimes spicate, the corolla about ½in. long and with short rounded lobes, light yellow. Rocky Mts. to W. Texas.

cc. *Floral lvs. much longer than the calyx.*

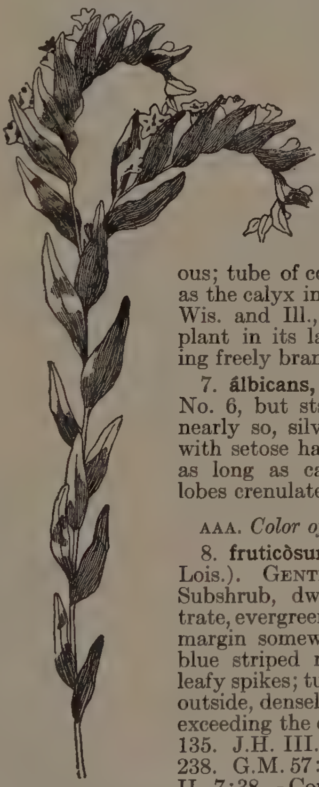
d. *Crests of throat little if at all projecting or arching.*

4. **canéscens,** Lehm. Puccoon, of the Indians. Red-Root. Indian Paint. Fig. 2185. Height 9–12 in. or more: lvs. oblong-linear or the upper ones broader, mostly silky pubescent and obtuse: fls. orange, the limb large and crests in throat prominent although not projecting: fls. nearly without pedicels. Plains and open woods, in sandy soil. Ont. to Ala., west to Ariz. B.M. 4389. G.M. 44:337.

5. **Gmélinii,** Hitchc. (*L. hírtum,* Lehm.). Height 1–2 ft.: lvs. lanceolate or the lower ones narrower: fls. bright orange, mostly pedicelled; glandular ring at base within bearing 10 very hirsute lobes or teeth. Pine barrens, Mich. to Fla. and Colo.

dd. *Crests of throat conspicuous and arching: fls. mostly very long and showy, often of two kinds.*

6. **angustifòlium,** Michx. (*L. linearifòlium,* Goldie). Height 9–12 in. or more: lvs. all linear: fls. of 2 sorts, the earlier and conspicuous kind bright yellow, with corolla-tube 1 in. or so long, later ones and those of the more diffusely branching plants with inconspicuous pale corolla, without crests in the throat and probably clistogenous; tube of corolla 2–4 times as long as the calyx in the large fls. Dry soil, Wis. and Ill., W. and S.—A showy plant in its large-fld. stage; becoming freely branched.



2185. Puccoon—Lithospermum canescens. (×½)

7. **álbicans,** Greene. Related to No. 6, but sts. fewer and simple or nearly so, silvery-hoary: lvs. linear, with setose hairs: corolla only twice as long as calyx, deep yellow, the lobes crenulate. S. Colo.

aaa. *Color of fls. blue or purplish.*

8. **fruticòsum,** Linn. (*L. prostràtum,* Lois.). Gentian-Blue Gromwell. Subshrub, dwarf, trailing or prostrate, evergreen: lvs. lanceolate-linear, margin somewhat revolute: fls. deep blue striped red-violet, in terminal leafy spikes; tube of corolla pubescent outside, densely villous at apex, much exceeding the calyx. S. Eu. Gn. 45, p. 135. J.H. III. 32:475. G.C. III. 30: 238. G.M. 57:455. G. 36:619. H.U. II. 7:38.—Correvon states that *L. prostratum,* which comes from the W. Pyrenees, is different from *L. frutico-*

sum; it is a low running species rather than erect-growing (as he defines *L. fruticosum* to be), covering the soil, and the lvs. are more lanceolate, shorter, broader, and reflexed at the edges: it is destroyed by limestone, which is not the case with *L. fruticosum.*

9. **purpùreo-cærùleum,** Linn. Sts. leafy and procumbent, reaching 2 ft. or more long, the fl.-sts. ascending or nearly erect and bearing leafy forked cymes: lvs. lanceolate, hairy: fls. rather large, rich blue, nearly sessile, usually surpassed by the lvs. Eu.

10. **Gástonii,** Benth. Beautiful plant, rare in the Pyrenees: a dwarf leafy perennial, adapted to alpine gardens, appressed-hairy, the erect branches 4–10 in. high: lvs. to 3 in. long, spreading and recurved, ovate-lanceolate, taper-pointed: fls. few, deep blue with star-like white eye, crowded near tips of branches; corolla-tube short, the lobes broadly ovate, the throat pubescent; calyx-lobes lanceolate, acute. B.M. 5926. G.C. III. 47:212.—Said to like lime.

11. **Zóllingeri,** A. DC. Perennial, with ascending sts., 4–6 in., silky-hairy: lvs. oval-oblong, usually mucronate, attenuate at base: fls. few, probably purple, the corolla nearly ½in. long; corolla-tube cylindrical-funnelform, twice longer than calyx; lobes of calyx linear, pilose. Java, but not since found there according to Koorders.—The plant in the trade under this name is said to make tufts of very rough glistening foliage, with sky-blue fls.: adapted to front-row of borders and large rockeries (in England).

The garden names of Lithospermum are confused and need to be re-studied. *L. cælestìnum,* Hort., is described as "a most desirable low-growing plant for the rockery," with pretty blue fls. in June. Probably Moltkia cærulea.—*L. Froèbellii,* Hort., is said to be "a dwarf compact plant with rosemary-like lvs. and deep blue fls. on erect sts. about 9 in. high."—*L. graminifòlium,* Viv.=Moltkia graminifolia.—*L. intermedifòlium,* Hort., is "a pretty dwarf shrubby plant with pale blue fls."—*L. intermèdium,* Hort., perhaps the same as the last, is "a pretty dwarf shrubby species, with fls. a lovely shade of blue." Somewhat shrubby, 8–10 in. high: lvs. narrow and slightly hoary: fls. tubular, drooping. G. 34:857. Probably these are Moltkias.—*L. petræum,* A. DC.=Moltkia.—*L. rosmarinifòlium,* Tenore. Evergreen, from Italy and Greece, 1–2 ft.: lvs. narrow, 1 in. or more long: fls. bright blue, striped white about ¾in. diam. Gn.W. 22:139.

L. H. B.†

LITHRÆA (*Llithi,* the Chilean name of *L. caustica*). *Anacardiàceæ.* Three species of evergreen S. American shrubs or small trees closely related to Schinus: lvs. alternate, simple or odd-pinnate: fls. small, greenish or whitish, in panicles; petals 5, valvate, stamens 10; disk annular in the staminate fls., cup-shaped and 10-lobed in the pistillate fls.; ovary superior, 1-celled with a basal, sessile ovule: fr. a dry subglobose drupe with a hard bony stone. The following species is occasionally cult. in S. Calif. **L. molleoìdes,** Engler (*L. Aroeírinha,* March.). Shrub, to 12 ft., glabrous: lvs. odd-pinnate; lfts. 5, rarely 3, lanceolate, acute, 1½–3 in. long; petiole 1–1½ in. long, like the rachis narrow-winged: panicles 2–3 in. long: fr. globose, ⅓in. across, whitish, lustrous. S. Brazil, Argentina. Flor. Brasil. 12, 2:83. **L. caùstica,** Miers, from Chile, has short-petioled simple, oval to ovate-oblong lvs. and pubescent panicles; it is said to be very poisonous. **L. Gillièsii,** Griseb. Tall shrub, 6–10 ft., the branches whitish gray, more or less dichotomous: lvs. 3-foliolate or 5-foliolate; lfts. lanceolate, the lower ones sessile, the upper narrowed below: fls. small, yellowish white, in few-fld. clusters: fr. a dry drupe. Brazil, Chile. R.H. 1914, p. 201.

Alfred Rehder.

LÍTSEA (Japanese name). *Lauràceæ.* Trees or shrubs of little horticultural importance, but may be planted S. Lvs. mostly alternate, coriaceous, usually evergreen: fls. diœcious, small, clustered in umbel-like cymes, mostly white or yellow; perianth-tube very short or sometimes ovoid or bell-shaped, the lobes usually 4–6; stamens mostly 6–12: fr. a dry or succulent drupe, on the enlarged perianth-tube. Species perhaps 150 in warm and tropical countries well around the globe, one of them (*L. geniculàta,* Benth. & Hook.) growing in shallow ponds, Ga. to La. Adanson's name, Malapoenna, is rejected by the Vienna or international rules.

LITTÆA: *Agave.*

LITTÒNIA (Dr. Samuel Litton, professor of botany in Dublin). *Liliàceæ.* One species is one of the so-called climbing lilies.

Tender, tuberous plants: fls. 6-parted, but in Littonia the segms. are not reflexed like a cyclamen, as in Gloriosa (which is another climbing lily), nodding, bell-shaped, orange or yellow, mostly 1 in. or more across; segms. oblong, acuminate; stamens 6, attached at base of perianth-segms.: caps. 3-celled; seeds scarlet or brown, about the size of a sweet pea, round, arranged in 2 series.—Species about 6, Arabia, S. Afr. and Trop. Afr.; most of them are erect not climbing herbs.

modésta, Hook. Slender and simple, either short and suberect or long and climbing or sarmentose: lvs. ovate to linear, produced into a tendril at the tip, the middle ones whorled and the upper ones opposite or alternate: fls. solitary in the upper axils, on slender pedicels; perianth-segms. provided with a small oblong nectary, partially closed by a ciliated scale on each side; style 3-cut. S. Afr. B.M. 4723. G.C. III. 36:183. Var. **Keìtii,** Hort., is an improved form, with larger and more abundant fls., the sts. longer, branched, and distinctly sarmentose. These plants require the cultural treatment of gloriosa.

Wilhelm Miller.
L. H. B.†

LITTORÉLLA (from Latin word for *shore,* from place of growth). Sometimes spelled *Litorella. Plantaginàceæ.* Small aquatic grass-like plants, one in Eu. and the northern part of N. Amer., offered abroad among hardy water-plants, and one little known in southern S. Amer. Perennial, somewhat succulent, with linear lvs. from the base: fls. monœcious, borne among the lvs., not showy, the staminate on scapes and pistillate sessile at base of lvs.; sepals 4; corolla 3–4-toothed; stamens 4, long-exserted; ovary single, with a long-exserted style. **L. uniflòra,** Aschers. (*L. lacústris,* Linn. *Plantàgo uniflòra,* Linn.). Growing in mats on borders of ponds and lakes, the lvs. 2–3 in. long, linear-subulate, bright green: stoloniferous. Newfoundland and Nova Scotia to Maine, Vt. and Minn.

L. H. B.

LIVE-FOREVER: *Sedum Telephium* and other *Sedums.*

LIVERLEAF: *Hepatica.*

LIVERWORT. A general name for a group of cryptogamia (flowerless plants), somewhat allied to mosses and known as Hepaticæ. Conocephalus and Marchantia have been offered by dealers in native plants as suitable for rockwork and bog-gardens. Lunularia is a common weed in greenhouses. See p. 6, Vol. I.

LIVING ROCK: *Ariocarpus.*

LIVISTÒNA (Patrick Murray, of Livistone or Livingstone). *Palmàceæ.* The most extensively grown genus of fan-leaved palms in commercial horticulture of the present day, its commonest representative being the "Chinese fan palm," *L. chinensis,* which is also known to the trade, and improperly, as *Latania borbonica.*

Trunks usually tall, stout, ringed below, clothed above with dead lf.-sheaths: lvs. spreading, orbicular, plicate, split to the middle or below; the segms. bifid, infolded, naked or fibrous along the margins; rachis short; ligule small, cordate, free; petiole long, stout, flat or rounded above, convex below, often spiny along the margins; sheaths margined with reticulate fibers: spadices long, at first ascending, pendent in fr., long-peduncled, loosely branched, the branches slender;

spathes many, long, tubular, compressed, sheathing the peduncle, thick, coriaceous, bifid or 2-lipped, 2-keeled or ancipital: no bracts or bractlets: fls. greenish: fr. smooth and shining, oblong-globose or ellipsoidal, black, blue, yellow or brown.—About 14 species from Trop. E. Asia, Malaya and Austral. From the seven allied genera mentioned under Licuala, Livistona is distinguished by the following characters: fls. hermaphrodite: carpels of the ovary globose, distinct or slightly cohering: styles short, distinct or cohering: albumen not twisted, broadly scooped out on the ventral side: branches of the spadices not bracted or the lower ones bracted. It is also remarkable in the group in having a thread in the lf.-segms., at least in many of the species.

In general, the members of this genus are by no means difficult to grow, though it is well to make some distinctions in culture between such strong-growing and comparatively hardy palms as *L. chinensis* and *L. australis*, and the more tender species from Java and northern Australia, among which *L. humilis*, *L. olivæformis* and *L. rotundifolia* are prominent. For those of the first section a strong loamy soil well enriched with thoroughly decayed stable-manure, good drainage, an abundance of water and a night temperature of 60° will provide satisfactory conditions for sturdy growth. The more tropical species, of which *L. rotundifolia* is a good example, make better progress in a somewhat lighter soil and a higher temperature, 65° to 70° being more congenial to them than the cool treatment accorded their stronger relatives. More shade is also required for the warmhouse species, in order to retain the rich green color that a healthy livistona should present.—Red-spider and white scale are two of the most troublesome insects to the grower of livistonas, the first being controlled to a great extent by thorough syringing, while the latter may be eradicated by the careful use of various insecticides, though avoiding the frequent application of extract of tobacco, the continued use of the latter substance often resulting in injury to the foliage of livistonas.—*L. australis* is a more stubby-growing plant than *L. chinensis*, the fan-like leaves are stiffer and less graceful, and the footstalks are more thoroughly armed with stout spines, while the leaves are also smaller in proportion to the plant than those of *L. chinensis*. *L. Hoogendorpii* and *L. olivæformis* are somewhat alike in young plants, but the first has many more and coarser spines on the footstalks, and the stalks of *L. Hoogendorpii* are generally longer, the leaves of both being much divided. *L. rotundifolia* and *L. altissima* are much alike in a small state, and the writer is inclined to think that the seeds of the latter are sometimes substituted for those of *L. rotundifolia*. The leaves of *L. rotundifolia* are flatter and more even in outline, those of *L. altissima* being somewhat undulated as though they were crowded on the stalk. In fact, small plants of *L. rotundifolia* are usually more symmetrical, and also have longer footstalks or petioles. (W. H. Taplin.)

2186. Livistona humilis.

INDEX.

altissima, 6.
australis, 7.
chinensis, 4.
decipiens, 10.
Hoogendorpii, 8.
humilis, 9.
Jenkinsiana, 1.
Mariæ, 7.
olivæformis, 3.
rotundifolia, 5.
subglobosa, 11.
Woodfordii, 2.

A. *Lvs. glaucous beneath.*

1. **Jenkinsiàna**, Griff. Trunk 20–30 ft., about 6 in. diam.: lvs. 5–6 ft. broad, reniform, flabellate, 70–80-fid, glaucous beneath, the divisions very narrow, straight, shortly and obtusely 2-toothed: spadix 2–3 ft., the branches forked; fls. in tiny bunches, small and green: fr. bluish. Assam. G.W. 12, p. 208.—Perhaps not specifically distinct from *L. chinensis*.

AA. *Lvs. not glaucous beneath.*

B. *Petioles without spines.*

2. **Woòdfordii**, Ridley. Petioles slender, without thorns, only ¼in. thick: lvs. orbicular, quite thin, 2 ft. long, 18 in. wide, split into very narrow acuminate lobes, the lower ones free almost to the base, the inner ones split only one-fourth of the way down: spadices very slender, the short slender branches protruding from the mouths of tubular brown sheaths: drupe globose, ⅜in. diam., bright red. Polynesia. First described in G. C. III. 23:177.—Nearly related to *L. australis*, but more graceful, with smaller fls. and fr.

BB. *Petioles spiny below the middle.*

C. *Length of spines ¼in. or less.*

3. **olivæfórmis**, Mart. (*Corýpha Gebánga*, Hort., in part). Sts. medium: lvs. glabrous; petiole somewhat 3-angled; spines retrorse, 1–3 lines long; segms. 12–15 in. long, deeply bilobed, the lobes very long, acuminate, linear, pendent, with or without very short filaments: fr. olive-shaped, solitary, or twin and connate to the middle. Brazil.

CC. *Length of spines 1 in. or more.*

D. *Shape of lvs. reniform.*

4. **chinénsis**, R. Br. (*Latània borbónica*, Hort., not Lam.). St. 6 ft. high, more than 1 ft. thick, gray, with approximate rings: lvs. many; petiole equaling the blade, covered to about the middle with retrorse brown spines, 1 in. or more long; blade reniform, 4–6 ft. diam.; segms. linear-lanceolate, long-pendulous, deeply forked, filiferous, the lower 1–2 ft. long, 1–2 in. wide, the middle 3 ft. long, the lobes acuminate, 4–8 in. long. China. G. 4:555. J.H. III. 48:185. Gn. M. 6:288. G.W. 10:202.

DD. *Shape of lvs. orbicular.*

5. **rotundifòlia**, Mart. (*Chamærops Bíroo*, Sieb. *C. Býrrho*, Hort.). Trunk 40–50 ft. high, 1–1½ ft. diam., erect or rather weak, brownish black, obscurely ringed; petiole 6 ft., with recurved spines 1½ in. long at the base; blade 3–5 ft. diam., suborbicular, appearing, though not truly peltate; segms. 60–90, connate for one-third their length, bifid to the middle, the lobes long-acuminate. Java. R.B. 21, p. 110.F. R. 1:301. S.H. 2:28.

BBB. *Petioles spiny from base to apex.*

C. *Segms. of lvs. free one-third of the way down.*

6. **altíssima**, Zoll. Mostly stemless, or rarely a few feet of trunk: lvs. bright

shining green, 1½–2 ft. long; segms. free one-third of the way down, bifid at the apex; petioles 2–6 ft., the base inclosed in a reddish brown network of woody fibers; spines stout, black, recurved. Java. A.F. 26:654.

cc. *Segms. free nearly to the base.*

d. *Position of segms. rigid, not drooping.*

7. **austràlis,** Mart. (*Córypha austràlis,* R. Br.). Sts. 40–80 ft. high, slender, and marked with circular scars: lvs. in a dense crown, orbicular, 3–4 ft. diam., divided to or below the middle into 40–50 narrow, plicate, acuminate segms., either entire or 2-cleft at the apex. Austral. B.M. 6274. Gn. 26, p. 337. V. 9:328. G.C. III. 30:287.—A form in which the young petioles and lvs. are blood-red color, said to be wild in S. Austral., has been grown under the name. *L. Màriæ,* Muell.

dd. *Position of segms. drooping.*

e. *Number of segms. 10–12.*

8. **Hoògendorpii,** Hort. St. tall, cylindrical, with triangular lf.-scars: petiole rounded on the back, 3–5 ft. long, red-brown at the base, olive-green above: spines stout, recurved, 1½–2½ in. apart, ¾–2½ in. long: lf. suborbicular, 4½–6 ft. diam.; segms. plicate, cuneate, pendulous at the apex and 5–7-lobed, the lobes acute. Java. I.H. 21:174. F.R. 1:427. Gn. 25, p. 392.

ee. *Number of segms. more than 12.*

9. **hùmilis,** R. Br. Fig. 2186 (redrawn from Martius). Sts. 4–16 ft. high: lvs. at length orbicular-cordate, 3 ft. diam., deeply divided; segms. narrow, plicate, acuminate, the filaments between the lobes altogether wanting or very minute or 1 in. long; petiole much flattened, with acute edges bordered with small prickles intermixed with larger ones, often ½in. long. N. Austral. G.W. 12, p. 208.

10. **decípiens,** Becc. A medium-sized palm with a trunk diam. of about 15 in.: lvs. with about 80 segms., the latter much pendent at the tips; petiole very spiny at the base, long and stiff; lf.-segms. very weak, hanging as though wilted: spadix long, but nodding when in fr. S. Austral.—Little known in cult. but interesting on account of its "weeping" lvs. It is perhaps the *Copernicia cerifera* of some dealers.

11. **subglobòsa,** Mart. A medium-sized palm: lvs. glabrous, the segms. 10–12 in. long, 2-parted nearly to the base, the lobes linear, very acuminate, pendulous: fr. subglobose, borne on a paniculate spadix about a foot long. Java.—Known in Java as "Sedangan."

L. Dournowiàna, Hort., is "a new palm with lvs. resembling those of Lantania borbornica," which is Livistona chinensis, Hab. (?).—*L. Muèlleri,* Bailey. A stout rugged palm about 20 ft.: lvs. densely crowded, the petiole about 3½ ft. long and covered with short curved prickles: fr. oval, nearly 6 in. long. Queensland, G.C. III. 32:431. Not in cult. in Amer.

N. Taylor.†

LLÀVEA (M. la Llave, who discovered the plant). *Polypodiàceæ.* One species, *L. cordifòlia,* Lag., related to Cryptogramma, native to the highlands of Mex., little cult. It grows 2 ft. high or more, with tripinnate lvs. that have fertile segms. on the upper part: sori under the reflexed edges of the segms. It requires warmhouse treatment.

LLÓYDIA (after Edward Lloyd, who found one of the plants in Wales). *Liliàceæ.* Small bulbous plants related to Erythronium, but with leafy stem.

Bulb narrow: st. slender, low, usually 1–2-fld.: radical lvs. few, linear or nearly filiform; st.-lvs. few: fls. small, white or yellowish, long-lasting; perianth 6-parted; segms. withering and persistent; stamens 6, hypogynous, shorter than the perianth: caps. obovoid or subglobose; seeds flattish.—Species 5 or 6, mountains in N. Amer., Eu., Asia.

serótina, Sweet (*L. alpìna,* Salisb. *Anthéricum serótinum,* Linn.). With an oblique, somewhat rhizomatous rootstock, and glands on the claws of the perianth-segms.: radical lvs. 2–4, linear: st. usually 1-fld., 3–6 in. long: lvs. 3–4, small, linear: fls. whitish, yellowish purple at its base, erect. Mountains of Colo. and north to arctic regions and in Eu.—Attractive spring fl.; grows in high mountains.

L. H. B.

LOÀSA (South American name). *Loasàceæ.* Comprises a few flower-garden annuals of minor value.

Annuals and perennials, herbs or subshrubs, of Trop. Amer., erect or twining: lvs. alternate or opposite, entire, lobed or decompound: caps. 3–5-valved from the apex, rarely twisted; ovary 1-celled; ovules numerous. The allied genus Blumenbachia differs in having caps. longitudinally 5–10-valved and most frequently spirally twisted.—Species 80–100. These plants are too much like nettles to deserve general cult., although their fls. are odd and interesting. The pain from their pricks may last several days. Each of the 5-hooded petals contains a bunch of stamens. They are treated as half-hardy annuals. *L. lateritia,* Hook. (*L. aurantiaca,* Hort.), a climbing vine, is *Blumenbachia lateritia* (*Cajophora lateritia,* Klotzsch), which see under Blumenbachia. It is a hispid stinging twiner, with opposite pinnate lvs.: fls. bright orange-red, or brick-red: little grown, but adapted to indoor work and to the open in summer: prop. readily by seeds or cuttings. It is in the American trade as an annual climbing plant: 6–20 ft.

a. *Petals white.*

vulcánica, André (*L. Wállisii,* Hort.). Erect, bushy annual, 2–3 ft. high: lvs. 3–6 in. broad, palmately 3–5-lobed, the lobes serrate, each with a long stalklet, the lateral ones often divided into 3 lfts.: sepals shorter than the petals; petals white; eye of fl. of 2 concentric red bands, with 5 yellow spots outside. Colombia. B.M. 6410. I.H. 25:302. R.H. 1894, p. 233.

aa. *Petals yellow.*

ùrens, Jacq. (*L. híspida,* Linn. f.). Annual, 1½ ft. high: lvs. alternate, 5 in. long, 3½ in. wide, pinnatifid; segms. lobed: fls. bright yellow, 1 in. across; sepals much shorter than the petals. June–Aug. Peru. B.M. 3057. G.C. III. 22:291. Gn. 25, p. 451.

trícolor, Lindl. Annual, 2 ft. high: lvs. opposite, bipinnatifid, very prickly: sepals as long as the petals; petals yellow; crown red; filaments white. Chile. B.R. 667.

L. H. B.

LOBÈLIA (Matthias de Lobel, or L'Obel, 1538–1616, a Flemish botanist and author; Latinized *Lobelius*). Including *Tùpa. Campanulàceæ.* Excellent flower-garden and border plants, annual and perennial.

Mostly herbs, some tropical species somewhat woody: lvs. alternate, sometimes the cauline ones reduced to bracts: fls. blue, red or yellowish, on 1-fld. pedicels, which are arranged in a terminal raceme; corolla gamopetalous and tubular, split down one side; lobes 5, the 3 on the lower side (as the fl. stands) somewhat united and forming a lip, the other 2 (1 on either side of the cleft or split) erect or turned back; calyx short-tubular

2187. Lobelia Erinus.

or globular, joined to the ovary, short-toothed; stamens 5, united into a tube around the single style, the tube often protruding from the cleft into the corolla: fr. a 2-valved caps.—Species 250 or more, in many parts of the world, well represented in E. U. S.

There are two horticultural groups of lobelias,—the annuals and the perennials. The annuals are low normally blue-flowered species suitable for bedding and edgings. They are of the easiest culture either from seeds or cuttings. See *L. Erinus* (No. 1). The perennials are again of two types,—the hardy and the half-hardy or tender. The hardy kinds are natives, of which *L. cardinalis* and *L. syphilitica* are the leading representatives. These inhabit bogs and low places, and the best results under cultivation are to be expected in moist and cool spots. The half-hardy sorts are chiefly derivatives of the Mexican *L. fulgens*, a plant deservedly popular in the Old World, but which has not attained great favor here. These species may be bedded out in the northern states. They are carried over winter in pots or in a cellar. They usually give good results the first year from seed, if started early; or seeds may be sown in the fall and the plants carried over in a frame. The hardiness of the hybrid perennial lobelias in this country is yet to be determined. It is probable that forms of *L. fulgens* will stand outdoors in the middle states if given winter protection. In the latitude of Washington they are hardy in winter but are scarcely able to withstand the summers.

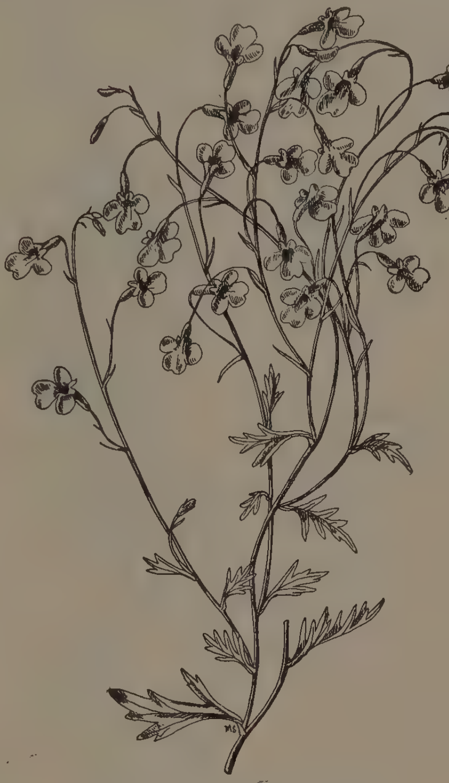
A. *Plant annual (or so treated), low and diffuse-growing.*

B. *Beards or hairy tufts on only the 2 lower anthers.*

1. **Erinus,** Linn. (*L. heterophýlla*, Hort., sometimes, not Labill. *L. grácilis*, Hort., not Andr. *L. bicolor*, Sims). Figs. 2187, 2188. Diffuse and half-trailing annual or perennial, much used for edgings: glabrous or slightly hairy below, 6–12 in. high: lvs. variable, the lower ones obtuse and obovate or spatulate and crenate-toothed, the upper ones oblanceolate or oblong (becoming linear and acute near the top of the st.), and mostly sharp-angle-toothed: fls. ½–¾in. across, on slender pedicels, light blue or violet with a lighter center (throat white or yellowish); calyx-lobes awl-like, spreading, as long as the corolla-tube; 3 lower lobes of corolla large and spreading. S. Afr. "Stony places in flats and on mountains." B.M. 514; 901.—One of the commonest of all annual edging plants, particularly for early season effects. In our hot climate, it often ceases blooming in midsummer, but with good soil, plenty of water, and occasional cutting back, it will bloom till frost. Seeds sown in Jan. and Feb., will give blooming plants by April and May. For fls. alone, rather than for edgings, the seeds may be started later, or even sown in the open ground. For definite results in edgings, however, it is usually better to start from cuttings. In the fall, lift the best plants, and grow them in pots through the winter as stocks from which to secure cuttings. Cuttings taken in late Jan. or Feb., should give blooming plants by May. Seedlings vary, and one cannot rely on them for definite effects in design work, although they may be best for the amateur who desires only fls. Some strains of seeds, however, come very true. The species is also a good pot-plant for the winter conservatory.

2188. Lobelia Erinus. (Natural size)



2189. Lobelia tenuior. (× ¼-⅕)

Lobelia Erinus is exceedingly variable. The forms fall into three groups:

(*a*) *Variation in habit:* Var. **compácta** or **erécta,** dense-growing forms suitable for low, close edgings: subvarieties are blue, white and so on. The most popular bedding forms belong to this strain. The name *erecta* is often used for the taller strains. Var. **grácilis,** with slender growth and suitable for vases or baskets: blue. Var. **pùmila.** Very dwarf.

(*b*) *Variation in color of foliage:* Golden Queen and Goldelse, with yellowish foliage. Also forms with bronzy foliage, but not constant.

(*c*) *Variation in color and size of fls.:* Var. **álba.** White. Var. **flòre-plèno.** Double. R.H. 1875:71. Var. **grandiflòra.** Various large-fld. forms. Var. **kermesìna.** Crimson. Var. **Lindleyàna.** Rose-color, with white eye. Var. **marmoràta.** Fls. marbled. Var. **Paxtoniàna.** Light blue with white eye: growth straggling. Var. **Royal Purple.** Purple-blue. Var. **speciòsa.** Large-fld., light azure-blue, with white eye. Var. **trícolor.** Fls. blue or pink, with white eye and carmine spots. Var. **hambúrgia,** Hort., has fls. bright blue with white eye; growth very rapid, slender, making it a handsome pot or basket plant. Var. **Ríchardsonii,** Hort. (*L. Ríchardsonii*, Hort.), has long spreading or drooping sts.: lvs. cordate and crisped: fls. light blue, in a long terminal raceme. *L. multiflora* of lists presumably belongs in this species: soft rich pink.

BB. *Beards or hairs on all the anthers.* The three following species are probably not in the American trade, although they are known as cult. plants. The names sometimes occur, but the plants which they represent are probably forms of *L. Erinus.* The descriptions will enable the student to distinguish whether the species occur.

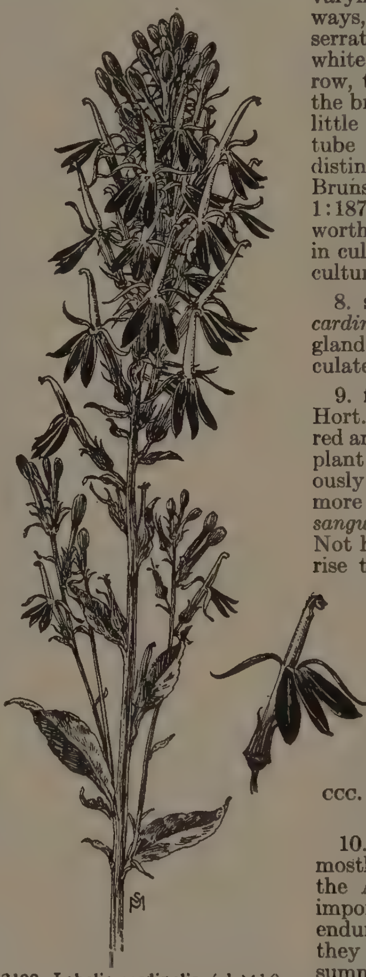
2. **grácilis,** Andr. (*L. trigonocaùlis,* Hook.). A foot or less high, slender, decumbent at the base, glabrous: lower lvs. ovate and deeply cut, the upper ones narrower and pinnatifid (becoming linear and entire at the top of the st.): fls. ½–¾in. across, blue with a whitish eye, the middle lower lobe strongly obovate, the 2 upper lobes small and curved and usually hairy; fl.-cluster long and open, more or less 1-sided: seed angled, not winged. New S. Wales. B.M. 741; 5088.

3. **heterophýlla,** Labill. Much like the last, but fls. larger (the middle lobe nearly 1 in. long), and the lower lvs. parted into linear lobes: seed winged. W. Austral. B.R. 2014. P.M. 9:101.

4. **ténuior,** R. Br. (*L. ramòsa,* Benth.). Fig. 2189. Erect or ascending, 12–18 in., pubescent: lower lvs. small, mostly ternately divided, the upper lvs. linear and mostly entire: fls. rather large, bright blue, borne far apart on very slender pedicels, the middle lobe much the largest and obovate: seed smooth and shining, compressed. W. Austral. B.M. 3784 (as *L. heterophylla*). B. 2:93. R.H. 1856:281; 1905:192. G.C. II. 15:105; III. 29:46. H.F. 7:27. G.W. 10, p. 2. G. 26:385.—It has received new attention in recent years.

AA. *Plant perennial (rarely biennial), usually tall or strict-growing.*

B. *Corolla very unequally bilabiate or 2-lipped, the lower lip 3-lobed and deflexed, the upper lip very small.*



2190. Lobelia cardinalis. (pl. × ⅕)

C. *Species: fls. blue (sometimes varying to white).*

5. **Kálmii,** Linn. A slender perennial (sometimes biennial ?), 6–18 in. high, glabrous, branched: lvs. narrow-spatulate to linear at the top of the st., remotely denticulate: fls. small (⅓in. long), very light blue, in a long, loose raceme, on filiform pedicels. On wet banks and slopes and margins of bogs, in northern states, Ont., Nova Scotia: prop. by offsets. B.M. 2238.—Sold by dealers in native plants. Useful for bog-planting.

6. **syphilítica,** Linn. Strong, weedy herb, 2–3 ft., glabrous or nearly so, mostly simple: lvs. thin, oblong-oval to lanceolate, attenuate to the apex but the point mostly blunt, small-dentate or crenate-denticulate, narrowed into a very short petiole: fls. about 1 in. long in a long, wand-like, racemose spike, blue or purplish, the tube about ½in. long; calyx hairy and enlarging in fr., the lance-acuminate lobes conspicuous, and bearing auricles in the sinuses. Moist places, eastern states (Maine to La.). B.R. 537; 32:6 (as *L. glandulosa*). Mn. 7:61. Gn.M. 5:344. Var. **álba,** Hort., has nearly white fls.—Interesting plant for bog-gardens and moist borders. In dry soils it will grow, but with less vigor.

CC. *Species: fls. in shades of red (or yellow or very rarely white).*

7. **cardinàlis,** Linn. Cardinal Flower. Indian Pink. Fig. 2190. Straight-growing, glabrous or very nearly so, 2–4 ft. tall, usually unbranched: lvs. narrow, varying from oblong-ovate to lanceolate, tapering both ways, the petiole very short or none, margin irregularly serrate: fls. bright intense cardinal (rarely varying to white), the tube 1 in. long, the 3 lower lobes very narrow, the fls. borne in a long racemose spike in which the bracts are mostly very narrow and the upper ones little exceeding the pedicels; calyx hemispherical, the tube much shorter than the long-linear lobes: seeds distinctly tuberculate. Wet places, as in swales. New Bruns. to Sask., and Fla. B.M. 320. G. 2:447. Gn.M. 1:187.—One of the most showy of all native fls., and worthy of cult. in any moist border. It has been long in cult., but has apparently given no important horticultural forms.

8. **spléndens,** Willd. (*L. texénsis,* Raf.). Like *L. cardinalis,* but more slender, the lvs. narrower and glandular-denticulate, mostly sessile: seeds little tuberculate. Wet places, Texas, west and south.

9. **fúlgens,** Willd. (*L. formòsa,* Hort. *L. cardinàlis,* Hort., in part). Very like the last, but fls. larger, deeper red and more showy, the 3 lobes of the lower lip broader: plant mostly pubescent (at least the foliage), and variously tinged or spotted with brown or bronze: bracts more leafy. Mex. B.M. 4002 (as *L. splendens* var. *atrosanguinea*).—Long in cult. and a most desirable plant. Not hardy without protection in the N. It has given rise to many horticultural forms, some of which (as "Queen Victoria") are commonly referred to *L. cardinalis.* The trade name *L. cardinalis atrosanguinea* probably belongs to this species. *L. cardinalis Nanseniana,* a purple-carmine sort, is probably *L. fulgens.* In Eu., *Lobelia fulgens* is one of the popular bedding plants, but it has never gained popularity in Amer. In this country it is usually grown in pots and treated as a conservatory subject.

CCC. *Species-hybrids or derivatives: fls. mostly in shades of red, pink or purple.*

10. **hýbrida,** Hort. The hybrid garden lobelias are mostly of French origin, and they are little known in the American trade, although they are occasionally imported by amateurs. It is doubtful whether they will endure the winters of the northern states, although they make excellent pot subjects for blooming in the summer border. They may also be planted in the open and lifted on the approach of winter: or new stock can be raised from divisions of the old plants, or from offsets, or from seeds. Many of these hybrids are most showy, and they should be better known in Amer. It is probable that they are derived chiefly from *L. fulgens,* although they are said to come largely from *L. cardinalis,* but *L. fulgens* and *L. cardinalis* are confused amongst gardeners. *L. syphilitica* has also, apparently, entered into some of these hybrid derivatives, particularly those with blue or purple colors, and *L. amœna* is supposed by some to be involved (see suppl. list). These hybrids are sometimes known collectively as *L. hybrida* and *L. perennis hybrida.* Two recent forms deserve separate mention (Nos. 11, 12):

11. **Gerárdii,** Hort. Habit of *L. fulgens* or *L. cardinalis:* lvs. lanceolate or lance-oblong, glabrous, denticulate: fls. in a heavy terminal spike or raceme, rich

violet, 1½ in. or more long. Obtained by Chabanne and Goujon of the Botanic Garden of Lyons, and intro. to the trade in 1895 by Rivoire Père et Fils, Lyons. The hispid calyx suggests *L. syphilitica.* R.B. 22, p. 112. I.H. 42, p. 268.—It varies into rose-color (var. **lugdunénsis**), and into coral-red, violet-purple, and the like. The pistillate parent was a form of *L. syphilitica* and the staminate parent was the "Queen Victoria" form of *L. fulgens.* The plant was named for M. Gérard, director of the botanical collection at Lyons.

2191. Lobelia Rivoirei. (×⅓)

12. **Rivòirei,** Hort., Fig. 2191, comprises still more recent types, with very large rose or pink fls. Gn. 56:182, which plate represents several derivative lobelias. G.C. III. 24:233. G.W. 4, p. 127.

BB. *Corolla somewhat equally 2-lipped, the lower lip only notched, the upper one 2-parted.*

13. **laxiflòra,** HBK. (*Syphocámpylus bícolor*, Don). Tall, branching herb or subshrub, with thinly hairy sts.: lvs. lanceolate or ovate-lanceolate, acuminate, sharp-denticulate: fls. nodding, on long, axillary pedicels, 1½ in. long, cylindrical, the stamens projecting from the side, red and yellow, pubescent. Mex.—An old plant requiring cool greenhouse cult., or thriving in the open in pots. It may also be planted out like *L. fulgens.* Var. **aùrea,** Hort., is a yellow-fld. variety. Var. **angustifòlia,** DC. (*L. Cavanillesii*, Hort.). Lvs. long and narrow, sometimes even linear: fls. scarlet with orange-yellow lip; corolla 1 in. long. Mex. B.M. 3600 G.C. III. 1:585; III. 57:263. A good tall subject for pots in a greenhouse and for planting-out in summer. Seeds sown in Feb. should give blooming plants in Aug.

BBB. *Corolla with all the lobes united by the tips into 1 lip.*

14. **Tùpa,** Linn. (*Tùpa montàna*, Hort. *T. Feuíllei*, Don. *Lobèlia Feuíllei*, Hort.). Very strong herb or subshrub (4–7 ft. tall), erect and mostly simple: lvs. oblong-oval, mostly acuminate, rugose, tomentose, denticulate: fls. in a long, terminal raceme, blood-red, 2 in. long, the hooded lip curving downwards and the column of stamens ascending; calyx-lobes short. Chile. B.M. 2550. G.C. III. 52:243. R.H. 1898, p. 189. G.W. 4, p. 139.—Cool greenhouse; hardy in southern states with protection.

L. amœna, Michx. Much like L. syphilitica, but the calyx plain and not hispid; corolla ½in. long, bright blue. N. C., south.—*L. ánceps*, Thunb. Perennial, blue-fld., with somewhat fleshy lvs. and 2-winged st. S. Afr. B.M. 2277 (as L. decumbens); 2519 (as L. rhizophyta).—*L. coronopifòlia*, Linn. Somewhat shrubby, with pinnatifid hairy lvs. and handsome blue fls. (sometimes 1 in. long), on long scapes. S. Afr. B.M. 644. G.C. II. 15:105.—*L. Dortmánna*, Linn. WATER LOBELIA. Aquatic perennial, 1 ft. or less, with lvs. radical and submerged, and small pale blue fls. on a scape. Useful amongst aquatic plants. Native.—*L. heterodónta*, Sprague. Erect, 3 ft. or more (perennial?): lvs. sessile, lanceolate, serrate: fls. pale green in a long raceme, the lobes about 1 in. long. Trop. Amer.—*L. horténsis*, DC., is a hybrid form of L. amœna, probably not in cult. now.—*L. inflàta*, Linn. INDIAN TOBACCO. Annual, of N. Amer., with ovate, pubescent, denticulate lvs., erect habit, and small blue or whitish fls.: herbage very acrid: plant formerly a domestic remedy.—*L. linnæoìdes*, Petrie. One of the New Zeal. lobelias: perennial, creeping: lvs. orbicular or ovate-orbicular, toothed: fls. white, purplish beneath, the corolla ⅓in. long.—*L. nicotianæfòlia*, Heyne. A striking perennial, 6 ft. and more: st. as thick as the arm at base: lvs. narrow-lanceolate, to 2 ft. long: fls. white (or pale lilac) in a branching infl. 2 ft. or more long. S. India. B.M. 5587. G.C. III. 35:195.—*L. sessilifòlia*, Lamb., from Kamtschatka: perennial, 1 ft. or so: fls. violet-blue, produced freely: lvs. broad, serrate: requires a wet place. G. 29:541.—*L. subnùda*, Benth. Annual from Mex., with radical lyrate lvs. and small pale blue fls. on long pedicels. G.C. III. 2:304.—*L. taliénsis*, Diels. Erect, to 4 ft. (perennial?): lvs. narrow-obovate or obovate-oblong: fls. blue, 1–1¼ in. long. W. China.

L. H. B.

LOBLOLLY BAY: *Gordonia Lasianthus.*

LOBOSTÈMON (Greek *lobe* and *stamen:* the stamens opposite the corolla-lobes). *Boraginàceæ.* Perennial herbs and shrubs, rough-pubescent or hispid, with alternate sessile often granular lvs., and white or blue fls. mostly in terminal cymes and heads. They are closely allied to Echium: species perhaps 50 in S. Afr. Apparently none is in the trade, although *L. formòsus*, Buek (*Èchium formòsum*, Pers. *E. grandiflòrum*, Andr.), is likely to be found in choice collections: shrubby and branched, 3 ft.: lvs. lanceolate to obovate-lanceolate: fls. reddish changing to blue, in spicate racemes. B.M. 1772. B.R. 36 (both as *E. fruticosum*).

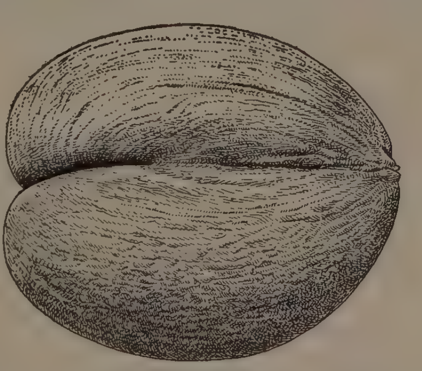
LOCHÈRIA (for Dr. Hans Locher of Zurich). *Gesneriàceæ.* Comprises a few species, which are now referred to Achimenes. In the trade are 2 species, *L. heterophýlla*, Œrst., or *L. ignéscens*, Klotzsch (see *Achimenes heterophylla*, p. 207), and *L. hirsùta*, Regel (see *Achimenes hirsuta*, DC., p. 208, suppl. list).

LOCO-WEED: *Astragalus; Oxytropis.*

LOCUST: Common locust is *Robinia Pseudacacia.* **Honey L.,** *Gleditsia triacanthos.* **Swamp** or **Water L.,** *G. aquatica.*

LODOÌCEA (said to be a modification of Laodice, daughter of Priam). *Palmàceæ.* DOUBLE COCONUT. COCO DE MER. MALDIVE-NUT, from the specimens found on the shores of the Maldive Islands in early days. One remarkable palm in the Seychelles (Indian Ocean), bearing an immense double nut which is one of the curiosities of the vegetable kingdom; the tree is sometimes seen in botanic gardens.

maldívica, Pers. (*Còcos maldívica*, Gmel. *Borássus Sonneràti*, Giseke. *Lodoícea callipỳge*, Comm. *L. sechellàrum*, Labill.). Fig. 2192. Tall diœcious palm, large in all its parts: lvs. palmately not deeply cut into many flabellate lobes or segms., the blade 6 ft. across, ovate-subrhomboid, cuneate at base, the segms. bifid, petiole 8–10 ft. long: fls. in axillary spadices which are subtended by several truncate spathes, the male fls in clusters in the hollows of the axis of the spadix and the female fewer and in cups or receptacles formed by a pair of bractlets; stamens in male fls. about 36, the pistil rudimentary; ovary in female fls. mostly 3-celled, the stamens being represented by staminodia: the great fr. usually 1-seeded, mostly 2-lobed: male spadix to 6 ft. long; female spadix of similar length, pendulous on a peduncle 1 ft. long; perianth ½in. long. B.M. 2734–8. G.C. II. 25:557; III. 4:732; 8:417. F.S. 5:523. Journ. N. Y. Bot. Gard. 7:8, 9 (1906).



2192. The double coconut.—Lodoicea maldivica.

The double coconut is one of the giants among palms, its straight and smooth trunk frequently reaching a height of 100 feet, and it is also a centenarian before its full growth is attained. The seeds of lodoicea are probably the largest known, the individual nuts being said to weigh sometimes fifty pounds, though the largest usually seen in collections do not likely exceed about fifteen pounds. The formation of such gigantic seeds requires a considerable period of time, and from the time of flowering to the full maturity of the seeds is said to cover a period of nearly ten years. The germination of such seeds is not an easy process, requiring much room and strong heat, the radicle being correspondingly large and running down for 3 feet or more before the top growth begins. Young plants require a strong and moist heat; and a considerable amount of root room, in combination with a light but rich compost, is best adapted to their needs. Seeds sometimes require three years to germinate. They are not advertised for sale at present, but have been sold as curiosities now and then in America. Their germination is a great event, but the plants are never grown to any considerable height, as they require too much care and room. The old nut remains attached at the surface of the ground until the tree is some years old. It is said that the heart of the crown of lvs. is eaten, as in the cabbage palm, and the lvs. are used in house-building. L. H. B.†

LŒSÈLIA (John Lœsel, an early Prussian botanist). *Polemoniàceæ*. Greenhouse plants, grown in the open far South, for their flowers.

Very close to Gilia, and often confused with it; and the genus is variously defined. As accepted by Peter in Engler & Prantl, it comprises 16 species in N.W. N. Amer., Mex., Cent. Amer. and northwestern Trop. S. Amer. The species occur very little north of Mex., however. As finally outlined by Gray (Suppl. Syn. Fl.), it has "fls. involucrate or involucellate; both bracts and calyx wholly or partly scarious; corolla funnelform, either regular or 1 or 2 sinuses deeper; seeds winged or margined, the surface becoming mucilaginous when wetted: suffruticose, rarely annual, with spinulose-toothed lvs."

L. coccínea, Don, is a handsome plant with brilliant rose-red tubular-trumpet-shaped fls. an inch long in terminal fascicles or compound bracted racemes, with stamens and 3-lobed stigma exserted: lvs. small and stiffish, oval or cuneate-oval, sharply and often spinulose dentate, grayish green: plant strict, pubescent, woody, perennial. Winter bloomer. It is offered in Calif. **L. tenuifòlia,** Gray, and **L. effùsa,** Gray, of S. Calif., are phlox-like plants offered some years ago. The former, Gray subsequently referred to *Gilia tenuifolia*, Gray, and the latter to *Gilia Dunnii*, Kellogg. L. H. B.

LOGANBERRY. Figs. 2193, 2194. The loganberry was originated by Judge J. H. Logan, of Santa Cruz, California. It is the result of a cross between the Aughinbaugh, a variety of *Rubus vitifolius*, the wild blackberry of California, and a red raspberry, probably the Red Antwerp. It was a chance hybrid developed from seed in 1881. Since that time the cultivation of the plant has increased extensively. It is cultivated all the way from southern California to British Columbia. However, while being a very vigorous plant, it is very tender and will not succeed where the temperature reaches zero unless protected and even under protection does not seem to fruit as heavily as it does where very mild winters are experienced.

A few years ago it was thought that the loganberry industry was overdone. This was due to the poor shipping character of the fruit and the fact that the berry was but little known; but at the present time not nearly enough fruit can be secured for canning and evaporating, and the berry promises to be one of the best horticultural assets of the Pacific coast. It is one of the very strongest-growing brambles and has a characteristic dark green foliage which it holds throughout the year.

The fruit when thoroughly ripe is of a purplish red and is very large, being one of the largest berries grown. In flavor and habits it shows the characteristics of both the blackberry and raspberry. Unless very ripe the fruit is exceedingly acid, but when thoroughly ripe has a pleasant acid flavor.

In western Oregon the fruit is coming to be of tremendous commercial importance. Salem is the principal center of the industry of the state, there being about 2,000 acres planted in that vicinity and the present outlook is that the acreage will be at least doubled. Extensive plantings are found all over western and southern Oregon. Many of the cultivators are taking hold of the loganberry industry in an extensive way, individual growers planting out as many as 200 acres in one season, while others are devoting from 100 to 200 acres purely for propagation purposes.

There are two other berries being grown in this same area which are very similar to the loganberry, one being the Primus, which is a blackberry-raspberry hybrid, introduced by Luther Burbank. It is an excellent home berry but cannot be picked easily until it is too soft to ship. It is also too shy a bearer to be commercially profitable. The Phenomenal is also a hybrid introduced by Luther Burbank and is supposed to be a cross between the California dewberry and the red raspberry. It is less acid than the loganberry. The fruit, if anything, tends to run a little larger, is a little brighter in color, the foliage is a lighter green and is a better shipper than the loganberry, but it does not yield nearly so well. It does not seem to be so long-lived and it is thought by the growers that it is not so good an evaporating berry as the loganberry. As far as the Pacific Northwest is concerned, the loganberry is driving the other hybrids from the market.

The loganberry tends to vary greatly in its seedlings and offers one of the best fields for plant-breeding to be found among small-fruits.

2193. Loganberry. (×⅜)

It will grow on any of the well-drained loams and is found to succeed well on the red hill soils and the silty loams along the rivers. It is thought by many of the growers that it prefers a clay subsoil rather than a gravelly or sandy subsoil. When planted on deep rich loams the plant seems to be longer-lived. There are commercial plantings in Oregon fourteen years old that are still very profitable. The principal requisite as regards soil and place is that the drainage must be very good, as the plant is an exceptionally heavy feeder.

The loganberry is propagated very easily by rooting the tips in the fall. In choosing plants to set out, one should choose either very vigorous-rooted tips, or else vigorous one-year-old plants. It is not advisable to plant the cutting or weak tips.

The fruit has not been grown commercially long enough as yet to demonstrate conclusively the best methods, especially as related to the distances of planting. Some growers put the rows as close together as 6 feet, some prefer 7 feet, but the larger number plant them 8 feet apart each way. The plants are set in the rows from 4 to 16 feet apart. When the plants are set as close together as 4 feet, the pruning is very different from that when planted at the greater distances. When planted close together the plants are kept headed back.

It is customary to train the plant as a trailer. It will be some time before it will be demonstrated thoroughly which method of pruning and training is superior, and naturally the distances at which the plants should be set will depend greatly on the soil in which they are grown.

The plants should be given very good care the first year. They do not tend to make a strong growth until the fall months, when the growth is very rapid. In the fall, good strong trellises should be provided. The most common method is to get good strong 7-foot cedar posts. These are set 30 feet apart. Two wires are generally strung on these posts, the first wire being 2 feet from the ground, the second one at or near the top of the post. Number 12 galvanized iron wire makes a very good wire for stringing. It is customary to run the rows north and south in order to obtain a good distribution of sunlight. There are many methods used in training the vines on the wires. Some growers practise the twining together of two or three fruiting canes, fastening them in a bundle to the wires. Others start out the canes in a fan shape. One of the best systems, and one that is meeting with considerable favor, is the weaving of the vines in and out among the wires. This weaving is performed whenever a shoot tends to come out in the row. This method seems to give a very good distribution of the fruiting canes along the wire. It is thought by many growers that it is well not to try to train the plants too high, since the finest berries are grown in the shade and one must take into consideration the convenience of the pickers.

So far, the pruning consists chiefly of cutting out the old canes and the general practice is to remove these canes as soon as the fruit is picked in July, thus minimizing any danger from disease.

The training of the new shoots for the succeeding year's growth may be done during the season or left until fall. A few of the growers wait until spring, thinking that if they have an unusually cold winter their plants are thus protected. In the growing season if the new plants interfere with the tillage or handling of the crop, they are generally kicked in under the fruiting canes. Sometimes small stakes are driven down to hold them in place.

The tillage given to the loganberry is very similar to that given other cane-fruits. If they suffer for lack of moisture or food, the berries become very small. Some growers practise plowing the ground up toward the plants in the fall and away in the spring. The most common practice is to leave the ground heaped up somewhat around the plants, as this usually means that the plants become deeper rooted and the moisture-supply is better held than when the ground is kept level.

The yield will vary tremendously, extremes probably being one to seven tons to the acre, with about four tons an acre as a very good average. A number of the growers the past year reported at least six tons, and one patch of 424 vines produced 425 crates. At the present prices and with the heavy yields the profits are very satisfactory. The wholesale price is 4 cents a pound, either for canning or evaporating. These figures mean a profit of $100 to $300 an acre. Some of the growers have contracted their crop up to 1920.

2194. The loganberry as grown in Oregon.

Thus far there are no troublesome insects and only one disease, namely, the cane anthracnose, which is very similar to the anthracnose that attacks other cane-fruits.

At the present time, the demand is many times greater than the supply for both canning and dried berries. The reason for this is that the loganberry has proved to be one of the best pie berries on the market. It makes a very excellent jelly, and its juice is a very refreshing beverage and is thought by many to be superior to grape-juice. Undoubtedly in the near future the juice manufacture will become a very extensive industry. At the present time such cities as Chicago, St. Paul, Omaha, and St. Louis, are unable to buy the quantities of dried and canned loganberries that they desire.

The berries are consumed fresh, but to be relished must be thoroughly ripe. Unless in a ripe condition the acid is so strong as to be unpleasant. Canned berries are generally put up in enameled tin cans, since the common tin cans are eaten by the acid.

In evaporating the berry, the common prune-drier is used. The berries are spread on trays of galvanized iron mesh wire. The trays are about 36 by 20 inches and the fruit is piled ½ to 1 inch deep on these trays. It takes from sixteen to twenty-four hours to evaporate the loganberry and probably twenty-four hours turns out a better product than when only sixteen hours is given. The tunnel drier is about as good a drier as can be used. The fruit is first placed in a temperature of 135° to 150° and this temperature is gradually increased until 165° is reached. The berries should be nicely dried in 16 hours; some seasons in less time. The product will be better than when the temperature is started low. The berries should be carefully selected and only ripe berries used, as the green berries do not dry well. It is almost impossible to dry them and even though they do dry they are too tart. If the fruit is uniformly ripe it dries very uniformly; but if it is over-ripe it tends to drip badly, caramels and burns easily. The wholesale price for the dried product is at the present time about 28 cents a pound. The berries dry down to about one-fifth, so that a twenty-five-pound crate will produce five pounds of dried fruit, although the percentage of the dried fruit to the fresh fruit will vary considerably. The first few pickings dry down more than those which come later, and should there be heavy rains the berries grow very large and luscious but contain relatively more water. It costs roughly about a cent a pound to dry the berries, although the commercial evaporators are charging about 3 cents for each dried pound. After drying, the berries are allowed to sweat and are handled about the same way as blackcap raspberries. They are then packed in boxes which hold either twenty-five or fifty pounds each.

Since the prune and the loganberry grow on similar soils successfully and both can be evaporated in the same drier, there are a number of growers who are combining these two crops. Thus a greater revenue is derived from the money invested in the evaporators. Loganberries come into bearing the second year and bear heavily the third, while the prune bears some the fifth year but not heavily until the seventh. The average evaporator will cost about $2,000 and such a building can handle the product of 40 acres.

As yet the loganberry is sold only in the United States. No attempt has been made to send it to foreign countries. This is due to the fact that the growers have not been able to satisfy the buyers who come to them. The future for this berry appears to be promising, the indications being that it will be many years before the demand can be satisfied.

C. I. Lewis.

LOGÀNIA (James Logan, Governor of Pennsylvania in Colonial times). *Loganiàceæ.* About 20 herbs and shrubs of Austral. and probably 1 in New Zeal., with mostly small white or flesh-colored more or less imperfect fls. Lvs. opposite: corolla campanulate or the tube cylindrical, the lobes 4 or 5; stamens 4 or 5, inserted in the tube; ovary 2-celled, becoming an ovoid or globular or oblong dehiscent caps. The loganias are seldom cult. They probably require the treatment of other coolhouse Australian things. *L. floribúnda*, R. Br., is an erect shrub with lanceolate or linear lvs. and white fls., of which the females are usually smaller than the males, in axillary short cymes or panicles. L.B.C. 12:1118. *L. latifòlia*, R. Br., is an erect shrub or undershrub, often glaucous, with broadly obovate to oblong-elliptic lvs. and white fls. in dense terminal cymes. Both species grow about 3 or 4 ft. high.

LOISELEÙRIA (after J. C. A. Loiseleur-Deslongchamps, physician and botanist in Paris, 1774–1849). Syn., *Chamælèdon, Chamæcistus. Ericàceæ.* A procumbent hardy evergreen shrub with very small, mostly opposite, closely set, entire lvs., and with small, usually rose-colored fls. in terminal, few-fld. umbels. A single species in the subarctic regions and high mountains of the northern hemisphere, allied to Kalmia and Leiophyllum, but calyx 5-parted, nearly as long as the bell-shaped corolla, stamens 5, with the anthers opening lengthwise and caps. 2–3-celled. Well adapted for rockeries, forming depressed tufts, but not easy to grow and rarely cult. It grows best in a sunny or partly shaded position in a porous, peaty and sandy soil, which is well drained and has a constant but moderate supply of moisture. Prop. by seeds treated like those of rhododendron or by cuttings of half-ripened wood under glass. **L. procúmbens,** Desv. (*Azàlea procúmbens*, Linn. *Chamæcístus procúmbens*, Kuntze). Only a few inches high, quite glabrous: lvs. petioled, oval to narrow-oblong, revolute at the margin, about ¼in. long: fls. 1–5, on rather short pedicels, pink or whitish, about ⅕in. across. July, Aug. L.B.C. 8:762. G.C. III. 53:343.

Alfred Rehder.

LÒLIUM (the ancient Latin name). *Gramineæ.* Darnel. Rye-Grass. Tufted grasses with flat blades and slender spikes.

Spikelets several-fld., sessile, placed edgewise on opposite sides of a zigzag axis.—Includes about 6 species of Old World grasses, 2 of which are intro. in the eastern states and are familiar fodder grasses of the same region. Perennial rye-grass was probably the first pasture grass to be cult. in Great Britain, and is grown there yet to a considerable extent, where it is said to occupy the same relative position of importance that timothy does here. A weedy species, *L. temulentum*, reputed to be poisonous to cattle, is supposed to be the "tares" of Scripture. It is the darnel, although that name is sometimes, but perhaps erroneously, applied to other species. Our 2 cult. species are short-lived perennials or the second scarcely more than an annual, not to be recommended for permanent pasture or lawn, but are frequently employed for hay or annual pasture. They are successful only in the moist regions of the eastern states. Seed sown in autumn or early spring, 25–30 lbs. to the acre. Rye-grass is often sown in lawn mixtures to give a quick covering to the soil, especially in large expanses such as parks and public grounds. It is replaced gradually by other constituents of the mixture that are more permanent. The loliums are agricultural grasses, scarcely grown for ornament or as garden plants.

perénne, Linn. Perennial Rye-Grass. One to 3 ft. high, with shining lvs. and slender spike, 4–10 in. long: spikelets 8–16-fld., awnless or only short-awned. Dept. Agric., Div. Agrost. 7:301.

multiflòrum, Lam. (*L. itálicum*, A. Br.). Italian Rye-Grass. Regarded by many as a variety of the preceding. Differs chiefly in having longer awns to the florets. Ibid 302.—This form of rye-grass is common on the Pacific Coast as a weed in open ground. It is there often called Australian rye-grass.

A. S. Hitchcock.

LOMÀRIA (Greek, *loma*, a forage). *Polypodiàceæ.* A generic name for a group of ferns, sometimes recognized as distinct from Blechnum, to which they are here referred. The species of ferns classed as Lomaria in Cyclopedia of American Horticulture have been referred to Blechnum in the present edition as follows: *L. ciliata* =*B. Moorei*, C. Chr.; *L. lanceolata*, Spreng.=*B. lanceolatum*, Sturm, *L. discolor*, Willd.=*B. discolor*, Keys; *L. gibba*, Labill.=*B. gibbum*, Mett.; *L. Boryana*, Willd.=*B. tabulare*, Kuhn; *L. spicant*, Desv.=*B. spicant*, Withers; *L. nipponica*, Kunze=*B. spicant* var.; *L. costaricensis*=Plagiogyria; *L. procera*, Spreng.=*Blechnum capense*, Schlecht., in Trop. Amer., Afr., New Zeal., etc.: rhizome short and stout, often woody, erect or prostrate: fronds many, 1–4 ft. or even to 10 ft. and more; pinnæ usually very numerous, 12 in. or less long, the margins minutely toothed. Variable. Var. *chilensis* (Kaulfuss) is sometimes mentioned in horticultural literature. G. 36:45.

A recent monograph on this group of ferns recognizes it as a distinct genus, but under the generic name Struthiopteris which is considered to take precedence of Lomaria.

R. C. Benedict.

LOMARIÓPSIS: *Stenochlæna.*

LOMÀTIA (from Greek word for *edge*, alluding to the winged seeds). *Proteàceæ.* About a dozen shrubs and trees in Australia and Tasmania, and in Chile, little known in cultivation, a very few of which are in the trade. They are coolhouse subjects, and suitable for the open in the warmer parts, grown primarily for the handsome dentate, pinnate or pinnatifid foliage. They require the general treatment of the Australian cool greenhouse things; propagated by well-ripened cuttings.

Leaves variable, alternate, from entire to toothed and bipinnatifid: fls. small, perfect, in pairs, borne in terminal or axillary racemes, white, pale yellow or reddish; perianth irregular, with an oblique tube open along lower side, the long lobes cohering in an ovoid-globular recurved limb; anthers sessile; ovary on a long stipe, with a long style and flat stigmatic disk: fr. a coriaceous follicle. **L. ferrugínea,** R. Br. (*L. pinnatifòlia,* Hort.), is the species most likely to be cult.: Chile: graceful in habit, handsome, with grevillea-like foliage: lvs. 2-pinnatifid, very dark green above and tomentose beneath, the segms. ovate and 3-toothed at the point: fls. about ½in. long, golden yellow and scarlet, rusty-hairy outside. B.M. 8112. G.C. III. 42:232, 233. *L. obliqua,* R. Br. Chile. Shrub or tree with densely leafy erect branches: lvs. ovate, crenate, leathery, smooth and bright green, 3–4 in. long: fls. white, with rusty hairs, about ⅓in. long, in short axillary racemes. *L. longifòlia,* R. Br. Austral. Erect, 8–10 ft., evergreen, glabrous or nearly so: lvs. linear-lanceolate to oblong-lanceolate, remotely serrate, 4–8 in. long: fls. greenish white, in terminal and axillary not elongated racemes, the perianth about ⅓in. long. B.M. 7698. B.R. 442.

L. heterophýlla is offered as an "elegant evergreen foliage plant."

L. H. B.

LOMÀTIUM (name refers to the *bordered* or winged fruit). *Umbellíferæ.* Under this name of Rafinesque's are now separated the American plants that have been referred to Peucedanum. More recently, however, the name Cogswellia has been substituted, although lacking priority, because Lomatium is held to be too much like the older Lomatia of Robert Brown. Lomatiums are mostly W. American plants, of about 60 species, growing in dry soil. They are mostly low or stemless perennial herbs from tuberous or fusiform roots, and compound (ternate, pinnate or dissected) lvs. From Peucedanum the genus differs, according to Coulter & Rose, as follows: "Peucedanum consists of tall and branching mesophytic plants of low fertile meadows of the Old World, with several umbels, conical stylopodium, and solitary oil-tubes; while Lomatium consists of low xerophytic plants of acaulescent habit belonging to the arid regions of W. N. A., with usually single umbels terminating simple elongated peduncles, no stylopodium, and often several oil-tubes." Horticulturally, the lomatiums are of small value, and they have not been cult. sufficiently to have given rise to cultural forms. A few of the species have been offered by dealers in native plants. They seem to thrive well in dry exposed places. They are interesting for the front row of hardy borders and for colonizing in wild open places, and for use in rockwork. Two of the species come as far East as Nebraska and Iowa.

A. *Peduncles usually slender, never swollen at the top.*

B. *Bractlets of involucel conspicuous, often broad or united at base.*

dasycárpum, Coult. & Rose (*Peucédanum dasycárpum,* Torr. & Gray). St. very short or wanting: peduncles several, stout, pubescent, 2 in. or less high: lvs. rather small, pinnately decompound, the numerous segms. short-linear: umbel 6–15-rayed, bearing white fls.: fr. nearly orbicular. S. Calif.

BB. *Bractlets small or wanting.*

C. *Lvs. narrow in outline, pinnate.*

Hállii, Coult. & Rose (*P. Hállii,* Wats.). Very short-stemmed, the peduncles 6–16 in. tall and glabrous: lvs. oblong in outline, the segms. ovate and deep-toothed or pinnatifid: umbel 3–6-rayed, bearing yellow fls.: fr. broadly elliptical, glabrous. Ore. and Wash., alpine.

CC. *Lvs. broad in outline, 1–3-ternate.*

platycárpum, Coult. & Rose (*P. símplex,* Nutt.). Often tall and stout, but sometimes nearly stemless: lvs. ternate or 2-ternate, the lfts. almost filiform to linear-lanceolate: umbel 3–15-rayed, bearing yellow fls.: fr. broadly oblong to nearly orbicular, sometimes emarginate at each end. Colo. and Utah to Mont. and Wash.

triternàtum, Coult. & Rose (*P. triternàtum,* Nutt.). Sometimes 2–2½ ft. high: lvs. 2–3-ternate, the lfts. narrow-linear to linear-lanceolate: fls. deep yellow: fr. narrowly oblong, glabrous. N. Calif. to Brit. Col.

AA. *Peduncle stout, swollen at the top.*

nudicaùle, Coult. & Rose (*P. leiocárpum,* Nutt. *Smýrnium nudicaùle,* Pursh). Stemless, glabrous: peduncle 12–16 in. tall, from a long, fleshy root: lvs. 1–2-ternate or 3-quinate, the lfts. thickish and ovate to narrow-lanceolate: umbel unequally 5–20-rayed, bearing yellow fls.: fr. narrowly oblong. Calif. to Brit. Col. and Idaho.

L. H. B.

LOMATOPHÝLLUM (Greek compound, referring to the *bordered leaves*). *Liliàceæ.* A few species in the Mascarene Isls., with the habit and perianth of Aloe, but differing in the red-margined or cartilaginous-margined lvs. and fr. a berry. They are fleshy subshrubs with hermaphrodite fls. and introrse anthers as in Sansevieria, but differ in having declined hypogynous stamens and several ovules in a cell, whereas Sansevieria has erect stamens inserted on the throat of the tube and solitary ovules. They are probably not in commercial cult. *L. borbónicum,* Willd. (*L. aloiflòrum,* Nichols.), the Bourbon aloe, is the one most likely to be found in amateur collections: st. 8 ft., thick at maturity: lvs. about 3 ft. long, horny-toothed, bordered red: fls. yellow, with brown-red outside, about ¾in. long. Mauritius. B.M. 1585 (as *Phylloma aloiflorum*).

LÒNAS (derivation in doubt; possibly a recombination of some of the letters of Santolina). *Compósitæ.* Species one, an unimportant hardy yellow-flowered "everlasting," known to the trade as the African daisy or *Athanasia annua.*

Leaves coarsely toothed or entire: heads small, in dense terminal corymbs, the fls. all alike; corolla yellow and regular: achene glabrous, angled and 5-ribbed; pappus cup-shaped, making a lacerated crown. The heads are about ⅜in. across, and composed entirely of disk-fls. There are 14 or more heads in the largest corymb, which may be 2 in. across. This plant was removed from Athanasia largely because it is an annual herb, while the athanasias are shrubs or subshrubs. A more fundamental reason for giving this plant a separate genus us that it has a cup-shaped pappus, while in Athanasia the pappus is absent or consists of small rather bristly chaff or else of hyaline hairs. The plant is of very easy cult.

inodòra, Gaertn. (*Athanàsia ánnua,* Linn.). AFRICAN DAISY. Annual, fleshy, branching, 1 ft. high: lvs. alternate, pinnatifid, the divisions linear, entire, remote: corymbs dense: seeds 5-ribbed, not hairy. Aug., Sept. Medit. region. B.M. 2276. J.H. III. 31:281.—Scarcely in cult. outside of botanic gardens, and of little horticultural importance.

N. TAYLOR.†

LONCHÌTIS (*lance,* from the shape of the fronds). *Polypodiàceæ.* A few species in Trop. Afr., allied to Pteris, differing in the sori: large ferns, the segms. broad and leafy, with interlocking veins: sori marginal, crescent-shaped, or kidney-shaped, on the ultimate sinuses, the pergamentaceous indusium formed of the reflexed membranous edge of the frond. They are warmhouse ferns little seen in cult. *L. pubéscens,* Willd., in several forms and under various names, is the species best known horticulturally. Stipes 1–2 ft. long, woolly pubescent, the fronds 2–4 ft. long, 3-pinnate, the lower pinnæ 1 ft. or more long, woolly or downy; pinnules lanceolate and deeply cut, to 1½ ft.

long; lfts. light green and soft, cut nearly or quite to the midrib into oblong-crenate segms. Trop. Afr., Cape, Mauritius and Seychelles.

LONCHOCÁRPUS (*lance-fruit*, from the shape of the pod). *Leguminòsæ*. Trees or climbing shrubs, in many species, in Trop. Amer. and Afr. and Austral., apparently not in the trade and little cult. Lvs. alternate, odd-pinnate, the lfts. opposite and sometimes stipellate: fls. papilionaceous, violet, purple or white, racemose or paniculate; standard very broad or rarely linear-oblong; wings oblique or falcate, lightly adhering to keel above the claw; keel arcuate or nearly straight; stamens 9 and 1: pod oblong or elongated, flat, indehiscent, the seeds few or only 1. An indigo is secured from the genus. *L. Bárteri*, Benth., is a glabrous climber from Guinea: lfts. 5–7, oblong, 5–6 in. long: fls. rose-colored, in clusters of 8 or 10. B.M. 6943. Said to be a good climber for the warmhouse. *L. ròseus*, DC., from S. Amer., has lfts. 13–15, lanceolate, acuminate: fls. large and showy, rose-colored. *L. latifòlius*, HBK., W. Indies, Cent. Amer. to S. Amer., a shrub or tree, has 2–4 pairs of elliptic or lance-oblong lfts., and pale purple fls.

On *L. speciòsus*, Bolus, about 10 years ago Harms founded the genus Bolusanthus (*B. speciòsus*, Harms). It is described by Bolus as a very distinct species with large and handsome bright blue fls.: tree, 15 ft. or more: lvs. stalked, the lfts. oblique-lanceolate and very acuminate: fls. 10–30 in terminal recurved or pendulous racemes. Delagoa and Transvaal.—Probably not cult. to any extent.

L. H. B.

LONGAN: *Euphoria*.

LONÍCERA (after Adam Lonicer or Lonitzer, a German physician and naturalist, 1528–1586). Including *Caprifòlium*, *Xylósteum*, *Nintòa* and *Chamæcérasus*. *Caprifoliàceæ*. HONEYSUCKLE. Ornamental shrubs grown for their handsome, usually profusely produced, often fragrant flowers and attractive berries.

Deciduous, rarely half-evergreen or evergreen, upright or climbing: lvs. opposite, usually short-petioled, entire or very rarely sinuately lobed, in a few species with distinct stipules: fls. in axillary peduncled pairs, each pair with 2 bracts and 4 bractlets, the latter often more or less connate into a cupula, sometimes wanting, or fls. in sessile whorls at the end of the branches; calyx 5-toothed; corolla with short or slender, often gibbous tube, 2-lipped or almost equally 5-lobed; stamens 5; ovary inferior, usually 2–3-, rarely 5-celled; the pairs sometimes partly or wholly connate: berry few- to many-seeded.—About 175 species throughout the northern hemisphere, in Amer. south to Mex., in Asia south to Java; about 90 species, besides numerous varieties and many hybrids, are in cult. For an account of the genus see Rehder, Synopsis of the genus Lonicera in Ann. Rep. Missouri Bot. Gard. 14:27–232, 20 pl. (1903).

The honeysuckles belong to our most popular ornamental shrubs. They are of easy cultivation and propagation, most of them are quite hardy and the flowers, though rather small, are profusely produced, mostly of pleasing and delicate colors varying from white or yellow to pink, purple or scarlet, and followed by attractive red, yellow, white, blue or black fruits; the shrubs are never coarse or weedy, do not produce dead wood to any extent, do not need much pruning, and are long-lived.

The upright or bush honeysuckles are very valuable for shrubberies, and the low procumbent species, like *L. spinosa* var. *Alberti*, *L. thibetica*, *L. pileata*, and *L. trichosantha*, are well suited for rockeries. Most of the cultivated species are hardy North, but *L. Standishii*, *L. fragrantissima*, *L. pileata*, *L. Ledebourii*, *L. quinquelocularis*, *L. Webbiana*, *L. rupicola*, and other Himalayan species are less hardy and need sheltered positions or protection North. Some of the handsomest in bloom are the well-known *L. tatarica*, *L. Korolkovii*, *L. spinosa* var. *Alberti*, *L. Maackii*, *L. Morrowii*, *L. Ledebourii*. For their sweet-scented early flowers, *L. Standishii* and *L. fragrantissima* are to be recommended. Honeysuckles with very decorative fruits are *L. Morrowii*, *L. tatarica*, *L. gracilipes*, *L. alpigena*, *L. trichosantha*, *L. Maackii* var. *podocarpa*, *L. chrysantha*. Nearly evergreen are *L. pileata* and *L. nitida*; half-evergreen, *L. fragrantissima* and *L. Standishii*. Loniceras thrive in almost any good garden soil, and prefer mostly sunny positions, but *L. canadensis*, *L. nigra*, *L. Ledebourii*, *L. hispida* and *L. Xylosteum* grow as well or better in partly shaded situations. Pruning may be done during winter except in the early-flowering species, like *L. Standishii*, *L. fragrantissima*, *L. gracilipes* and *L. hispida*. The climbing honeysuckles are well adapted for covering walls, arbors and other trelliswork; they have mostly handsome and often sweet-scented flowers, in the hardy *L. tragophylla* as long as 3 inches, in the tender *L. Hildebrandiana* as long as 7 inches, but are somewhat deficient in foliage, with the exception of *L. japonica*, and liable to become leafless and unsightly at the base, and therefore may be mixed with other climbers, like ampelopsis, akebia, clematis. They perhaps show their beauty to the best advantage when allowed to ramble over shrubs and small trees. Those of the Caprifolium group are mostly hardy North, with the exception of the species of southern Europe and *L. hispidula*, while of the Nintoa group *L. japonica* and *L. Henryi* are hardy North, at least in a sheltered position; these species make also a very handsome ground-cover, and, like *L. Periclymenum*, grow well in shade, but the others prefer sunny positions. Propagation is by seeds sown in fall or stratified and by cuttings of ripened wood; also by greenwood cuttings under glass in summer, but the species of the Periclymenum group grow less readily in this way. Most species hybridize very easily and only seeds collected from isolated plants should be used for propagation. *L. spinosa* var. *Alberti* is sometimes grafted high on stems of *L. tatarica*, thus forming a small weeping tree.

KEY TO THE SPECIES.

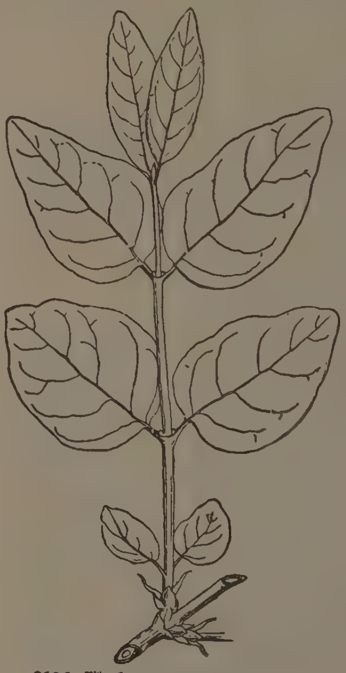
A. *Fls. in axillary pairs.*
B. *Habit upright, sometimes prostrate.*
C. *Branches with solid white pith.*
D. *Corolla with regular or nearly regular 5-lobed limb.*
E. *Tube of corolla equally tubular or campanulate: bractlets at least half as long as ovary: berries distinct: lvs. scarcely exceeding 1 in.*
F. *Stamens and style inclosed in the tube: fr. bright red.*
G. *Lvs. glabrous beneath* . . . . 1. **syringantha**
GG. *Lvs. tomentose beneath* . . . . 2. **thibetica**
FF. *Stamens and style exserted: fr. whitish or pale bluish purple, bloomy* . . . . 3. **spinosa**
EE. *Tube of corolla more or less ventricose or gibbous.*
F. *Bracts narrow, usually subulate.*
G. *Ovaries and frs. distinct: fr. red.*
H. *Style exceeding the limb: fls. whitish, in pairs* . . . . 4. **canadensis**
HH. *Style shorter than limb: fls. usually red, solitary* . . . . 5. **gracilipes**
GG. *Ovaries and frs. connate or partly connate or ovaries tightly inclosed by a cupule.*
H. *Frs. partly or wholly connate, red: bractlets wanting: corolla ventricose, pinkish* . . . . 6. **tangutica**
HH. *Frs. seemingly connate, blue, bloomy: corolla gibbous, yellowish white* . . . . 7. **cærulea**
HHH. *Frs. distinct, red: ovaries inclosed by a cupule: lvs. evergreen or half-evergreen.*
I. *Habit prostrate: lvs. ¼–1⅓ in. long, usually narrowed at base* . . . . 8. **pileata**
II. *Habit upright: lvs. ¼–½ in. long, usually rounded at base* . . . . 9. **nitida**
FF. *Bracts broad, enveloping the ovaries.*
G. *Bractlets wanting: fls. white: fr. scarlet.*
H. *Ovary glabrous or glandular: tube slender below the middle, gibbous at base* . . . . 10. **hispida**
HH. *Ovary setose and glandular-pilose: tube thick, saccate at base* . 11. **chætocarpa**
GG. *Bractlets large; fls. yellow or scarlet: fr. purplish black.*
H. *Stamens equaling the limb: lvs. glabrous or slightly pubescent* . . . . 12. **involucrata**
HH. *Stamens not exceeding the mouth: lvs. pubescent beneath: corolla orange and scarlet outside* . . . . 13. **Ledebourii**
DD. *Corolla 2-lipped.*
E. *Terminal bud wanting, replaced by 2 axillary buds; buds with 2 outer valvate scales: fr. red.*
F. *Lvs. acuminate* . . . . 14. **Standishii**
FF. *Lvs. acute or obtusish* . . . . 15. **fragrantissima**
EE. *Terminal bud present.*
F. *Fls. pale yellow: fr. red.*
G. *Bractlets connate into a cupule: buds with 2 valvate outer scales* . . . . 16. **iberica**
GG. *Bractlets minute: buds small, with imbricate scales* . . . . 17. **oblongifolia**
FF. *Fls. dull violet or brownish red; bractlets small in distinct pairs: frs. connate.*
G. *Berries red* . . . . 18. **alpigena**
GG. *Berries bluish black* . . . . 19. **orientalis**
CC. *Branches hollow, with brown pith: fls. 2-lipped; ovaries distinct.*
D. *Corolla light or deep pink, sometimes white, but not changing to yellowish.*
E. *Lvs. above 1 in. long, usually glabrous: upper lip of the corolla divided nearly or quite to the base.*
F. *Bractlets distinct; upper lip divided to the base* . . . . 20. **tatarica**
FF. *Bractlets connate into pairs; upper lip divided not quite to the base* . . . . 21. **amœna**
EE. *Lvs. 1 in. or less long, usually finely pubescent: upper lip divided to about the middle* . . . 22. **Korolkovii**
DD. *Corolla white or pink, changing to yellow: hybrids between No. 20 and Nos. 26 and 29.*
E. *Apex of lvs. obtusish or acute* . . 23. **bella**
EE. *Apex of lvs. acuminate.*
F. *Under side of lvs. nearly glabrous: bractlets glabrous or glandular-ciliate: fls. often pink* . . . . 24. **notha**
FF. *Under side of lvs. pubescent: bractlets ciliate: fls. white, sometimes pinkish* . . . . 25. **muendeniensis**
DDD. *Corolla white or pale yellow, changing to yellow or yellowish, rarely slightly pinkish.*
E. *Peduncles longer than petioles.*
F. *Winter-buds small, obtusish: ovary glabrous.*
G. *Bractlets small, glabrous or glandular* . . . . 26. **Ruprechtiana**
GG. *Bractlets as long or half as long as ovary.*
H. *Lvs. acuminate: bractlets half as long as ovary* . . . . 27. **muscaviensis**
HH. *Lvs. obtusish or acute, rarely short-acuminate: bractlets as long or nearly as long as ovary.*

I. *Under side of lvs. sparingly pubescent*............28. **minutiflora**
II. *Under side of lvs. densely pubescent* .29. **Morrowii**
FF. *Winter-buds rather large, pointed, with long-ciliate scales: ovary glandular.*
G. *Fls. whitish, often slightly pinkish: lvs. generally ovate to obovate, acute or abruptly acuminate, glabrous or soft-pubescent* ....30. **Xylosteum**
GG. *Fls. pale yellow changing to deeper yellow: lvs. rhombic-ovate to ovate-lanceolate, acuminate, pilose* ....31. **chrysantha**
EE. *Peduncles shorter than petioles.*
F. *Calyx with 5 acute teeth: lvs. acuminate*..............32. **Maackii**
FF. *Calyx truncate, splitting, scarious: lvs. obtuse or acutish*................33. **trichosantha**
BB. *Habit climbing: branches hollow.*
C. *Corolla less than 1 in. long, tube slightly ventricose; corolla dull red*.34. **Henryi**
CC. *Corolla over 1 in. long, with slender tube.*
D. *Bracts leafy, ovate; corolla 1¼–2 in. long, white or purplish: lvs. more or less pubescent, half-evergreen*...................35. **japonica**
DD. *Bracts subulate: lvs. quite glabrous, evergreen.*
E. *Length of corolla 3–4 in.: color changing from white to yellow*...................36. **longiflora**
EE. *Length of corolla 5–7 in.: color changing from yellow to orange-red*.............37. **Hildebrandiana**
AA. *Fls. in usually 6-fld. whorls at the end of the branchlets: lvs. below the infl. connate (except in No. 53).*
B. *Tube of corolla 3 or more times longer than limb; limb nearly equal or short 2-lipped. (See also No. 47.)*
C. *Limb regular: lvs. not ciliate* ......38. **sempervirens**
CC. *Limb short, 2-lipped.*
D. *Lvs. ciliate*...................39. **ciliosa**
DD. *Lvs. not or slightly ciliate*.......40. **Brownii**
BB. *Tube of corolla as long to twice as long as limb; limb deeply 2-lipped.*
C. *Corolla ½–1, rarely to 1½ in. long; tube of corolla ventricose, or slightly gibbous, pubescent inside (except in No. 46).*
D. *Bractlets at least half as long as ovary; corolla ½–¾ in. long, with gibbous tube*............41. **hispidula**
DD. *Bractlets one-third as long or shorter.*
E. *Disk of connate lvs. elliptic, pointed at both ends, usually concave.*
F. *Lvs. ciliate: branchlets pubescent: corolla glandular outside*.................42. **hirsuta**
FF. *Lvs. not ciliate: branchlets glabrous: corolla usually glabrous outside.*
G. *Under side of lvs. pubescent*.................43. **glaucescens**
GG. *Under side of lvs. glabrous*.44. **dioica**
EE. *Disk suborbicular or oval, rounded at the ends, nearly flat.*
F. *Style and tube inside pubescent: disk usually with dense whitish bloom above*.45. **prolifera**
FF. *Style and tube inside glabrous: disk bright green above or only slightly bloomy*.................46. **flava**
CC. *Corolla 1½–3 in. long; tube of corolla slender, not ventricose, glabrous inside (except in Nos. 47 and 51).*
D. *Whorls of fls., at least the lower ones in the axils of connate lvs.*
E. *Tube of corolla 3 or 4 times as long as limb, stamens much shorter than limb*..........47. **implexa**
EE. *Tube of corolla not more than 1½ times as long as limb; stamens about as long as limb.*
F. *Bractlets minute or wanting: whorls of fls. only 1 or 2*....48. **Caprifolium**
FF. *Bractlets about half as long as ovaries: whorls several*..49. **americana**
DD. *Whorls of fls. in peduncled heads or spikes.*
E. *Lvs. below the infl. connate.*
F. *Fls. in elongated spikes with remote whorls*...........50. **Heckrottii**
FF. *Fls. in dense heads.*
G. *Corolla about 3 in. long: head short-peduncled with 1 or 2 whorls*.....51. **tragophylla**
GG. *Corolla 1½–2 in. long: heads long-peduncled, often in 3's, with several whorls*...............52. **etrusca**
EE. *Lvs. all distinct: fls. in a dense head*......................53. **Periclymenum**

Subgenus CHAMÆCERASUS.

Section Isoxylosteum.

1. **syringántha**, Maxim. Upright slender-branched shrub, glabrous: lvs. elliptic to oblong, obtuse or acutish, dull bluish green, ½–1 in. long: peduncle ⅛in. long; cupule shorter than ovaries; calyx-teeth lanceolate; corolla tubular-funnelform, ½in. long, pale rosy lilac, fragrant; stamens and style included: fr. red. May, June: fr. in Aug. W. China. B.M. 7989. R.H. 1907, p. 281. Var. Wolfii, Rehd. Branches more spreading, often procumbent: lvs. narrower, usually acute: fls. lilac-carmine. W. China.—Very graceful shrub producing its fragrant fls profusely.



2196. Fly honeysuckle.—Lonicera canadensis. (×⅜) No. 4.

2. **thibética**, Bureau & Franch. (*L. rupicola* var. *thibética*, Zabel). Fig. 2195. Shrub, to 5 ft., with wide-spreading slender, often procumbent branches: lvs. oblong-lanceolate, acute, rarely obtusish, dark green and glossy above, white-tomentose beneath, ½–1¼ in. long: peduncle to ⅓in. long, cupule about half as long as ovaries; corolla tubular-funnelform, pale purple, about ½in. long, slightly tomentose outside, fragrant; stamens and style included: fr. red. May, June; fr. in Aug., Sept. W. China. S. T. S. 1:45. R. H. 1902, p. 449.—A dense much-branched shrub well suited for rocky slopes.

3. **spinòsa,** Jacquemont. Rigid spinescent shrub to 4 ft.: lvs. linear-oblong, about ½in. long: fls. ¾in. long with slender cylindric tube and spreading limb; stamens and style exserted: fr. pale bluish red or whitish, bloomy. Himalayas. Var. **Álberti,** Rehd. (*L. Álberti,* Regel). Shrub with slender arching or procumbent branches: lvs. linear or linear-lanceolate, sometimes with 2–4 teeth at the base, glaucous or bluish green, ½–1¼ in. long: fls. on slender, erect peduncles, rosy pink, fragrant. Turkestan. Gt. 30:1065. B.M. 7394.—Very graceful shrub.

2197. Lonicera gracilipes. (×½). No. 5.

Section ISIKA.

4. **canadénsis,** Marsh. (*L. ciliàta,* Muhl.). Fig. 2196. Shrub, to 5 ft.: lvs. ovate or oval, acute, rounded or cordate at the base, ciliate, pubescent beneath when young, 1½–3 in. long: fls. slender-peduncled, always in pairs, yellowish, sometimes slightly tinged red, ⅔in. long: fr. light red. April, May: fr. in June, July. Canada to Pa. and Mich. B.B. (ed. 2) 3:281.

5. **gracílipes,** Miq. (*L. Phylomèlæ,* Hort.). Fig. 2197. Shrub, to 6 ft., almost glabrous: lvs. roundish-ovate to oblong-ovate, ciliate, bright green, often with reddish margin, 1–2½ in. long: peduncles slender, nodding, usually 1-fld.; corolla pink, rarely white, ⅔in. long: fr. rather large, pendulous, bright red. April, May; fr. in June. Japan. G.F. 10:265 (adapted in Fig. 2197). S.I.F. 2:73. The form described here is var. *glàbra,* Miq.; the typical form has the lvs. ciliate and pubescent beneath, particularly on the midrib, and is not in cult. Var. **albiflòra,** Maxim. A form with white fls. Var. **glandulòsa,** Maxim. Lvs. and fls. pubescent: ovaries glandular.—A graceful species; one of the earliest to bloom, and very handsome in June with its pendulous scarlet frs.

6. **tangùtica,** Maxim. Low shrub with spreading branches: branchlet glabrous: lvs. obovate to obovate-oblong, acute or obtusish, cuneate at base, ciliate, usually sparingly hairy above, glabrous and glaucescent beneath, ½–1¼ in. long: fls. slender-stalked, pendulous; bracts subulate; calyx-teeth minute; corolla tubular-funnelform, slightly ventricose below the middle, limb upright, whitish, flushed pink, ½in. long; style exserted: fr. bright red. May, June; fr. in July. W. China. Gt. 40, p. 581.

7. **cærùlea,** Linn. Much-branched erect or spreading shrub, to 5 ft., with glabrous or pubescent branchlets: winter-buds often several, superposed: lvs. often stipulate, oval or obovate to oblong-lanceolate, pubescent or almost glabrous, pale or glaucous green, 1–2 in. long: fls. short-peduncled, yellowish or greenish white, ⅓–½ in. long: fr. blue, bloomy; berries connate only at the base, but wholly covered by the connate bractlets and hence seemingly connate. April, May. N. Eu., N. Asia and N. Amer. B.M. 1965.—A very variable species; the typical form is a spreading shrub with elliptic to oblong lvs. glabrescent like the branchlets and occurs in Eu. and N. Asia. Var. **altàica,** Sweet (*L. Pállasii,* Ledeb.). Branchlets and lvs. hirsute: fr. subglobose. N. Eu. to Japan. Var. **edùlis,** Regel. Lvs. oblong to lanceolate, pubescent like the branchlets: fr. oblong. E. Siberia, Tibet. Var. **graciliflòra,** Dipp. (*L. Karelìnii,* Hort., not Bunge). With upright rather slender, bright red branches, slightly pubescent: lvs. ovate to ovate-oblong, puberulous on both sides: fls. with slender tube. Var. **villòsa,** Torr. & Gray (*L. villòsa,* Muhl. *Xylósteum Solònis,* Eaton). Shrub, to 3 ft. with upright branches: winter-buds upright, always solitary: lvs. oval or obovate to oblong, usually pubescent: corolla campanulate, tube as long or shorter than limb. N. Amer. south to Tenn., Wis. and Calif. B.B. (ed. 2) 3:281.

8. **pileàta,** Oliver. Low, spreading shrub, sometimes prostrate: lvs. evergreen or half-evergreen, ovate to oblong-lanceolate, obtusish, dark green and glossy above, glabrous, ¼–1⅓in. long: fls. short-stalked, upright; bracts connate into a cupule inclosing the ovaries; calyx with a cap-like downward production at the base; corolla funnelform, whitish, gibbous at the base, ⅓in. long, fragrant; stamens exserted: fr. purple, surrounded at the base by the persistent cupula. April, May; fr. in July. Cent. and W. China. B.M. 8060. G.C. III. 35: 243; 47: 236. R.H. 1909, pp. 376, 377. H.I. 16:1585.—Though the fls. are insignificant, the handsome evergreen foliage and the purple frs. render it a desirable shrub; it resembles a small-lvd. privet.

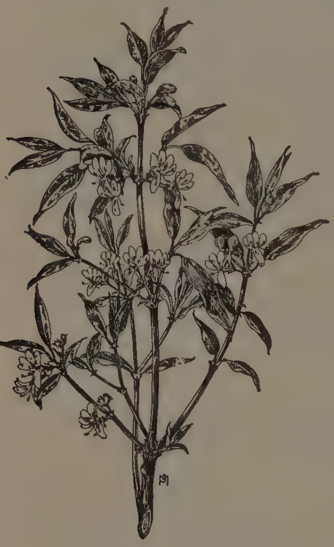
9. **nítida,** Wilson. Shrub, to 6 ft., with upright branches: lvs. broadly ovate to ovate-oblong, obtuse, subcordate to broadly cuneate at the base, glossy above, glabrous except short hairs on the midrib above and on the very short petioles, ¼–½in. long: corolla slightly larger: otherwise like the preceding species, of which it is possibly only a variety. W. China.—Apparently hardier than the preceding species.

10. **híspida,** Pall. Shrub, with spreading bristly-hispid or glabrescent branches: winter-buds large, 2-valved: lvs. obovate to oblong, ciliate and hirsute, at least when young, sometimes glaucous beneath, 1½–2½ in. long: fls. nodding, white, funnelform, strongly gibbous at the base, hairy outside, 1–1¼ in. long; bracts ovate, ciliate, whitish, ¾–1 in. long; bractlets none; ovaries glabrous or glandular: fr. oblong, bright red. April, May; fr. in June, July. Altai to Himalayas.

2198. Lonicera involucrata. (×⅓). No. 12.

—Distinct and handsome with its rather large white fls. and later with its red bracteate frs.

11. **chætocárpa,** Rehd. (*L. híspida* var. *chætocárpa*, Batalin). Shrub, to 6 ft.: branchlets hispid and glandular: lvs. ovate-oblong or elliptic-ovate, usually acute, sparingly pubescent above, more densely beneath and reticulate, 1⅓–3 in. long: bracts pubescent outside, about 1 in. long: corolla white, funnelform, with rather thick tube, saccate at the base, pubescent and glandular outside, about 1½ in. long; ovaries glandular and setose: fr. ovoid, bright red, setose. April, May; fr. in June, July. W. China.



2199. Lonicera Standishii. (×⅓)

12. **involucràta,** Banks (*Distègia involucràta*, Cockerell). Fig. 2198. Shrub, to 3 ft., with upright branches, glabrous or somewhat pubescent: lvs. elliptic-ovate to oblong-lanceolate, bright green, slightly pubescent beneath when young, 2–5 in. long: fls. erect, long-peduncled; corolla yellowish or slightly tinged red, viscid, pubescent, with short erect lobes, about ½in. long; stamens as long as limb: berries black, shining, almost inclosed by the enlarged purple bractlets. May–July. Ont. to Alaska, south to Mex. B.R. 1179. B.B. (ed. 2) 3:282. Var. **flavéscens,** Rehd. (*L. flavéscens*, Dipp.). Lvs. light green, thin, oblong- or ovate-lanceolate, 3–5 in. long: corolla less gibbous, yellowish. Brit. Col. to Wyo. and Utah. Gt. 37, p. 7. Var. **serótina,** Koehne. Lvs. oblong-ovate to oblong: corolla flushed bright scarlet. June–Aug. Colo. A very striking variety on account of its brightly colored fls. Var. **hùmilis,** Koehne. Dwarfer and with smaller lvs.

13. **Ledeboùrii,** Esch. (*L. intermèdia*, Kellogg). Similar to the preceding, but more vigorous: branches sometimes sarmentose, to 15 ft. long: lvs. of firmer texture, dark green above, pubescent beneath: fls. more salver-shaped, with rounded, spreading lobes, scarlet-red outside, ¾in. long; stamens shorter than lobes. May–July; fr. July–Sept. Calif. Gt. 2:64. R.H. 1843:373. H.U. 5:6. B.M. 8555.—Much handsomer than the preceding, but more tender.

14. **Stándishii,** Carr. (*L. sinénsis*, Hort. *L. Fórtunei*, Hort. *L. fragrantíssima* of some). Fig. 2199. Half-evergreen shrub, with spreading branches, to 6 ft.: branchlets with reflexed bristly hairs: lvs. coriaceous, oblong-ovate to ovate-lanceolate, acuminate, ciliate, bristly hairy on both sides or glabrous above, 3–4 in. long: fls. on rather short, curved peduncles, white or slightly blushed, very fragrant, ¼–½ in. long; bracts linear-lanceolate, exceeding the ovaries: frs. partly connate, scarlet. March, April; fr. in June. China. B.M. 5709. G.C. III. 5:245. R.H. 1873, p. 148. Var. **lancifòlia,** Rehd. Lvs. narrow-lanceolate. W. China.

15. **fragrantíssima,** Lindl. (*L. caprifolioìdes*, Koch. *L.* or *Caprifòlium Niaguarílli*, Hort.). Similar to *L. Standishii*, but with long and slender recurving and almost glabrous branches: lvs. broadly ovate or obovate, acute, almost glabrous, but bristly on the midrib beneath and ciliate, 1–2½ in. long: corolla glabrous outside. March–May. G.C. III. 5:245. R.H. 1873, p. 169. B.M. 8585.—Less hardy than *L. Standishii*. Both have handsome half-evergreen foliage and very early, sweet-scented, though not very showy fls.

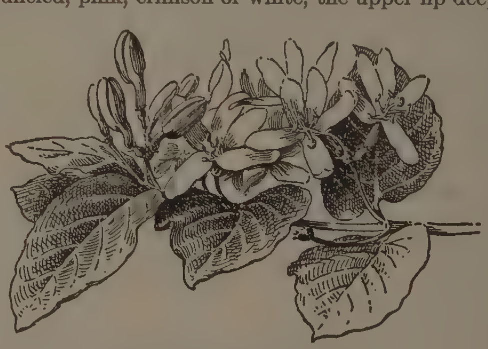
16. **ibérica,** Bieb. Much-branched upright shrub, to 6 ft.: branchlets pubescent: lvs. roundish-ovate or ovate, acute or obtusish, cordate or rounded at base, grayish green, ciliate, pubescent on both sides, ¾–1⅓ in. long: fls. short-stalked; bracts leafy, exceeding the ovary; corolla yellowish white, changing to yellow, finely pubescent, ½in. long: fr. bright red. June; fr. in Sept. Transcaucasia, Persia. Var. **microphýlla,** Dipp. Lower: lvs. ½–¾ in. long.

17. **oblongifòlia,** Hook. Shrub, to 5 ft.: lvs. almost sessile, oval-oblong, obtuse, pubescent beneath, 1–2½ in. long: fls. slender-peduncled; bracts and bractlets minute or indistinct; corolla hairy outside, yellowish white, sometimes tinged purplish: berries dark red, usually wholly connate. May, June; fr. in July. Que. to Manitoba, south to Pa. and Mich. B.B. (ed. 2) 3:281. Var. **altíssima,** Rehd. (*L. altíssima*, Jennings). Branchlets and lvs. glabrous. Pa.

18. **alpígena,** Linn. Shrub, to 8 ft., with stout branches: lvs. oblong-obovate or oblong, short-acuminate, glossy and dark green above, light green and often pubescent beneath, 2–4 in. long: fls. long-peduncled, with short usually yellowish green tube and brownish red limb: berries connate, bright scarlet, shining. April, May; fr. in Aug., Sept. Mountains of Cent. and S. Eu. H. W. 3, p. 129.—Very handsome in fruit.

19. **orientàlis,** Lam. Shrub, to 10 ft., almost glabrous: lvs. elliptic or ovate to oblong-ovate, rarely oblong-lanceolate, dark green above, pale or glaucescent beneath, 2–4 in. long: fls. short-peduncled, pale violet or pinkish: fr. black, wholly connate. May, June. W. Asia to Kamschatka. The typical form has ovate to ovate-lanceolate, acuminate lvs. pubescent beneath and is not in cult. Var. **caucásica,** Zabel (*L. caucásica*, Pall.). Lvs. oval to elliptic-oblong, glabrous and glaucescent beneath. Gt. 11:359. Var. **longifòlia,** Dipp. (*L. Kesselríngii*, Regel. *L. kamschática* and *L. savránica*, Hort.). Lvs. smaller, oblong to lanceolate, glabrous: corolla smaller, scarcely gibbous at base. Gt. 40, p. 124.—Fls. and frs. not very conspicuous.

20. **tatárica,** Linn. Fig. 2200. Shrub, to 10 ft., almost glabrous: lvs. cordate or rounded at the base, ovate to ovate-lanceolate, ciliate, sometimes slightly pubescent beneath when young, 1–2½ in. long: fls. slender-peduncled, pink, crimson or white, the upper lip deeply divided, spreading, with the outer lobes free to the base: bractlets distinct, small, glabrous: fr. red, rarely yellow. May, June; fr. in July, Aug. S. E. Russia to Siberia. B.R. 31. R.H. 1868:392. Gt. 18:627. B.B. (ed. 2) 3:282.—Variable in size and shade of fls. Var. **álba,** Loisel. Fls. white. Var. **grandiflòra,** Rehd. (var. *álba grandiflòra*, Dipp.). Fls. larger, white. Var. **sibírica,** Pers. (var. *rubriflòra*, DC. var. *rùbra*, Sweet. *L. punícea*, Sims. var. *purpùrea*, Hort.). Fls. bright red. B.M.



2200. Lonicera tatarica. (×⅔)

2469. Var. **latifòlia,** Loud. (var. *grandiflòra rùbra,* Pepin. var. *spléndens,* Regel). Lvs. large, to 4 in. long: fls. pink, the lobes bordered light pink. R.H. 1844: 109. Gt. 18:627, fig. 1. Var. **punícea,** Lindl. (var. *speciòsa,* Carr.; var. *pulchérrima,* Regel). Similar to the preceding form, but fls. deep pink. R.H. 1868: 392, fig. 1. Gt. 18:627, fig. 5. Var. **angustifòlia,** Kirchn. (*L. angustàta,* Wender.). Lvs. narrow-lanceolate: fls. bright pink. Var. **lùtea,** Loud. (var. *xanthocárpa,* Endl.). Frs. yellow. Var. **nàna,** Alphand. Low, dense shrub: lvs. ovate-lanceolate, narrowed at base: fls. small, pinkish. Var **parvifòlia,** Jaeger (var. *grácilis,* Carr. *L. parvifòlia,* Hayne, not Edgew.). Lvs. smaller, obtuse: fls. pure white, small, with broad and short lobes: fr. orange-red. Var. **micrántha,** Trautv. (var. *pubérula,* Regel & Trautv. *L. micrántha,* Regel). Branchlets, peduncles, bracts and corolla puberulous: lvs. pubescent beneath. Not in cult.: the plant cult. under this name is usually the preceding variety or *L. xylosteoides.* Var. **pállens,** Rehd. Lvs. smaller and narrower, bluish green: fls. small, finally almost white.

21. **amœ̀na,** Zabel (*L. Korolkòvii floribúnda* × *L. tatárica*). Branchlets nearly glabrous: lvs. ovate, rounded or subcordate at the base, glabrous, 1–2 in. long: fls. very numerous, slender-stalked; bractlets small, connate into pairs; corolla ¾in. long, pink (var. *ròsea,* Zabel) or white (var. *álba,* Zabel), outer lobes of the upper lip divided nearly to the base. May, June. Of garden origin. Var. **Arnoldiàna,** Rehd. (*L. Korolkovii* × *L. tatarica*). Lvs. narrow-elliptic to oblong-lanceolate, ¾–1½ in. long, nearly glabrous, grayish green: fls. white, flushed pink. Very floriferous and exceedingly graceful.

22. **Korolkòvii,** Stapf (*L. floribúnda* var. *Korolkòvii,* Zabel). Fig. 2201. Shrub, to 12 ft.: branchlets short-pubescent: lvs. ovate to narrow-elliptic, acute, rounded or narrowed at the base, slightly pubescent above, more densely beneath, bluish green, ½–1 in. long: fls. on slender peduncles ½–1 in. long; bractlets about one-third as long as ovary, connate into pairs; corolla light pink, rarely white, the upper lip divided about one-half or slightly more; tube slightly gibbous: fr. bright red. May, June; fr. in Aug. Turkestan. G.F. 7: 35. M.D. 1910, p. 117*a*. Var. **floribúnda,** Nichols. (*L. floribúnda,* Zabel, not Boiss. & Buhse). Lvs. broadly ovate to ovate, slightly cordate or rounded at the base (in the typical form generally elliptic and narrowed at the base). Gt. 42, p. 103, figs. 4–6. M.D. 1910, p. 117*d*. Var. **Zábelii,** Rehd. (*L. Zábelii,* Rehd. *L. floribúnda glabréscens,* Zabel). Lvs. glabrous, in shape like those of the preceding variety. Gt. 42, p. 103, figs. 1–3. M.D. 1910, p. 117*e*. Var. **auròra,** Koehne. Lvs. ovate to elliptic: corolla with slender tube, rosy pink; bractlets about half as long as ovaries.

2201. Lonicera Korolkovii. (×⅓)

23. **béllа,** Zabel (*L. Mórrowii* × *L. tatárica*). Upright shrub with spreading branches: branchlets usually slightly pubescent: lvs. ovate to ovate-oblong, obtusish or acute, usually truncate at the base, slightly pubescent beneath or nearly glabrous, 1–2 in. long: peduncles about ½ in. long; bractlets nearly orbicular to ovate, one-half to three-fourths as long as ovary; corolla about ½in. long, white to pink, with spreading lobes, the outer lobes of the upper lip free to the base: fr. red. May, June; fr. in July, Aug. Garden origin.

24. **nótha,** Zabel (*L. Ruprechtiàna* × *L. tatárica*). Upright, strong-growing shrub: branchlets glabrous or nearly glabrous; lvs. ovate to ovate-lanceolate, rarely elliptic, acuminate, rounded or truncate at base, slightly pubescent or nearly glabrous beneath, 1½–2½ in. long: bractlets ovate, about one-third as long as ovary, rarely longer, glabrous or glandular-ciliate: corolla ¾in. long, white, yellowish or pinkish, upper lip upright, divided to the middle or sometimes nearly to the base, tube gibbous, short: fr. red. May, June; fr. in July, Aug. Garden origin.

2202. Lonicera Xylosteum. (×⅔). No. 30.

25. **muendeniénsis,** Rehd. (*L. bélla* × *L. Ruprechtiàna*). Upright shrub: branchlets pubescent: lvs. ovate to ovate-lanceolate, acuminate, rounded or narrowed at the base, dark green above, pubescent beneath, 1⅓–3 in. long: bracts about as long as ovary; bractlets broadly ovate, one-third to one-half as long as ovary, ciliate: corolla white or yellowish white or sometimes slightly pinkish, upper lip upright, divided nearly to the base; filaments pubescent below the middle: fr. red. May, June; fr. in July, Aug. Garden origin. Gt. 42, p. 101 (figs. 4–6).

26. **Ruprechtiàna,** Regel. Shrub, to 12 ft.: lvs. ovate-lanceolate to lanceolate, acuminate, usually dark green above, grayish pubescent beneath, 2–4 in. long: fls. on rather long peduncles, pure white at first, glabrous outside; bractlets only glandular-ciliate, small, about one-third of the ovary: fr. red or sometimes yellow. May, June. Manchuria. Gt. 19:645. Var. **xanthocárpa,** Zabel (*L. gibbiflòra,* Dipp.) Fls. smaller, yellowish: fr. yellow. Var. **calvéscens,** Rehd. Lvs. almost glabrous except hairy nerves on under side.—This specics and *L. Morrowii* are likely to hybridize with *L. tatarica;* these hybrids are very common, and may be recognized by the glabrescent foliage and the tinge of pink in the fls. The true *L. Ruprechtiana* is much rarer in gardens than its hybrids.

27. **muscaviénsis,** Rehd. (*L. Mórrowii* × *L. Ruprechtiàna*). Upright shrub with spreading branches: branchlets pubescent: lvs. ovate to oblong-ovate, acuminate, dark green and sparingly pubescent above, densely beneath, 1⅓–2 in. long: bractlets ovate, ciliate, half as long as ovary: corolla white, upper lip upright, divided to somewhat below the middle; filaments glabrous: fr. bright red. Garden origin. Gt. 42, p. 101 (figs. 1–3).

28. **minutiflòra,** Zabel (*L. micranthoìdes* × *L. Mórrowii*). Upright shrub with spreading branches: branchlets puberulous: lvs. ovate-oblong to oblong, obtuse, acutish or short-acuminate, sparingly pubescent below, ¾–1½ in. long: bractlets ovate-oblong, nearly as long as ovary: corolla with spreading limb, upper lip divided below the middle, ½in. long, whitish;

stamens about half as long as limb: fr. red. May, June; fr. in July, Aug. Garden origin. A.F. 28:672.—On account of the narrow and rather small foliage, the frs. show to better advantage than in many allied honeysuckles.

29. **Mórrowii,** Gray. Shrub, to 6 ft., with wide-spreading branches: lvs. oval or oblong-ovate, obtusish or acute, dark green above, grayish tomentose beneath, 1–2 in. long: fls. peduncled, pure white at first, pubescent outside, upper lip divided nearly to the base, with spreading lobes; bractlets pubescent, about as long as ovary: fr. blood-red. May, June. Japan. A.F. 11:1267. Gng. 5:329. J.H.S. 35, p. 362. S.I.F. 2:73.—Very distinct in its habit; handsome in fl. and in fr. It hybridizes easily with *L. tatarica* and the hybrids are more common in gardens than the true species.

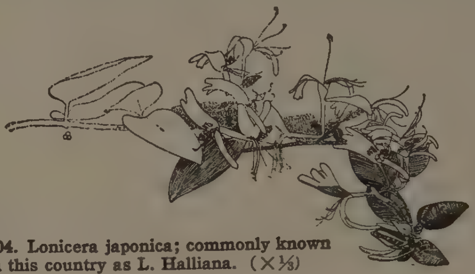
30. **Xylósteum,** Linn. Fig. 2202. Shrub, to 10 ft.: lvs. broadly oval to obovate, acute, dull green, sparingly pubescent above or glabrous, more densely pubescent beneath, rarely nearly glabrous, 1–2½ in. long: fls. peduncled, yellowish white, often slightly tinged red, hairy outside; bractlets pubescent, suborbicular, about half as high as ovary: berries dark red. May, June; fr. in Aug., Sept. Eu., W. and N. Asia, sometimes escaped from cult. B.B. (ed. 2) 3:282. H.W. 3, p. 127.—Not so ornamental as most allied species.

31. **chrysántha,** Turcz. (*L. gibbiflòra*, Rupr.). Upright shrub, to 12 ft. with upright sts.: branchlets pilose, rarely glabrous: lvs. rhombic-ovate, to rhombic-lanceolate, acuminate, dark or bright green above and nearly glabrous, pilose beneath, at least on the veins, 2–5 in. long: peduncles ½–1 in. long; bractlets distinct, ovate, one-third to one-half as long as ovary; corolla ¾in. long, yellowish white changing to yellow, upper lip divided about one-half, tube strongly gibbous, short: fr. coral-red. May, June; fr. in Aug., Sept. N.E. Asia to Cent. Japan. Gt. 12:404.—Particularly handsome in autumn with its bright red fr. Var. **Regeliàna,** Zabel (*L. Regeliàna*, Kirchn.). Fls. smaller, more yellowish.

32. **Maàckii,** Maxim. Fig. 2203. Upright shrub, to 15 ft.: branchlets short-pubescent: lvs. elliptic-ovate to ovate-lanceolate, acuminate, dark green above, paler beneath, usually only pubescent on the veins on both sides, 2–3⅓ in. long: peduncles shorter than petioles; bractlets half as long or as long as ovary; calyx distinctly 5-toothed, nearly as long as ovary; corolla ¾in. long, white, fading to yellowish, glabrous outside, fragrant, upper lip upright, divided to the middle or below, tube short, not gibbous; stamens usually only half as long as limb: fr. dark red. June; fr. in Sept.–Nov. N.E. Asia to Cent. Japan. Gt. 33:1162. G.C. III. 41:265. G. 29:411. G.W. 4, p. 235. Var. **podocárpa,** Franch. Lower and more spreading: lvs. broader, oval to elliptic, short-acuminate: ovaries raised above the bracts on a very short but usually distinct stalk: fls. slightly smaller. Cent. China. Var. **erubéscens,** Rehd. A form of the preceding variety, with larger fls. flushed pinkish.—A very desirable species, the latest of the bush honeysuckles to bloom; the type is showier in bloom, while the var. *podocarpa* is most beautiful in fr. which lasts, like the dark green foliage, into Nov.

2203. Lonicera Maackii. (×⅓)

33. **trichosántha,** Bureau & Franch. (*L. ovàlis*, Batalin). Spreading shrub with long and slender sometimes partly procumbent branches: lvs. ovate, obovate or oval, obtuse or acutish, usually rounded at the base, nearly glabrous, 1–2 in. long: peduncles shorter than petioles; bractlets broad, connate into pairs, truncate, about half as long as ovary; calyx rather large, nearly truncate, scarious, cleft: corolla slightly longer than ½in., changing from pale to bright yellow, tube strongly gibbous: fr. bright red. June; fr. in Aug., Sept. W. China.—Very handsome with its bright red fr.



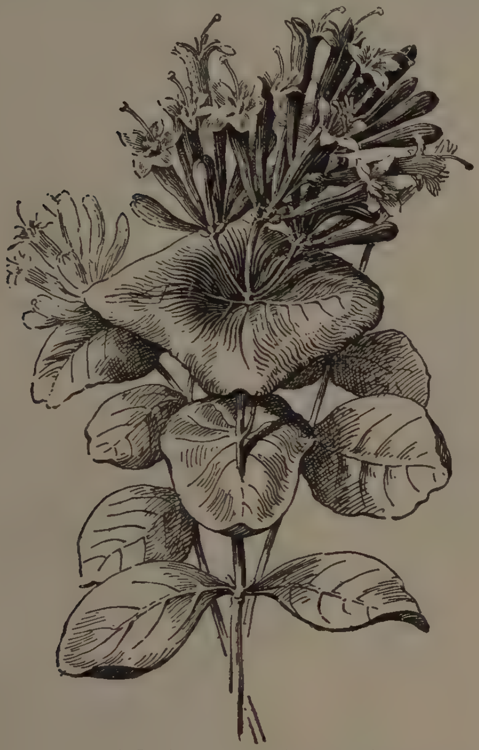
2204. Lonicera japonica; commonly known in this country as L. Halliana. (×⅓)

Section Nintooa.

34. **Hényri,** Hemsl. Climbing or prostrate, half-evergreen: branchlets densely strigose: lvs. ovate-lanceolate to lanceolate, ciliate and usually pubescent on the midrib beneath, 1½–3½ in. long: fls. in the axils at the end of the branchlets, often crowded, short-stalked; bracts subulate, short; bractlets roundish, one-third as long as ovary; corolla ¾in. long, dull purplish or yellowish red: fr. black. June–Aug.: fr. Sept., Oct. W. China. B.M. 8375. Var. **subcoriàcea,** Rehd. Lvs. subcoriaceous, ovate-oblong, 2–4 in. long, not ciliate: corolla slightly longer, tube longer than limb. W. China.

35. **japónica,** Thunb. Fig. 2204. Climbing, to 15 ft. high: branchlets usually pubescent when young: lvs. half-evergreen, roundish-ovate to oblong, pubescent beneath or almost glabrous, 1½–3 in. long: fls. short-pedicelled, white, changing to yellow, often purplish outside, very fragrant, glandular-pubescent outside, 1½–2 in. long; bracts leafy, ovate or oval; bractlets broad, half as long or as long as ovary: fr. black, separate. June–Aug. China, Japan; naturalized in some places from N. Y. to N. C. B.B. (ed. 2) 3:280. G.M. 45:613. M.D.G. 1901:609. Var. **aùreo-reticulàta,** Nichols. (*L. reticulàta aùrea*, Hort. *L. brachýpoda reticulàta*, Hort.). A form of var. *flexuosa*, with the smaller and shorter lvs. handsomely netted yellow. B.H. 21:59. G.Z. 9:48. Var. **flexuòsa,** Arb. Kew. (*L. flexuòsa*, Thunb. *L. brachýpoda*, DC.). Less high climbing: lvs. ovate or oblong, obtusish, pubescent on both sides while young or only on the veins beneath: peduncles usually as long as petioles or shorter; corolla 1–1½ in. long, usually purplish outside, with the upper limb divided into short lobes; bractlets broad, as long as ovary. Var. **chinénsis,** Baker (*L. chinénsis*, Wats.). Lvs. ovate, acute, ciliate and pubescent only at the veins beneath, often with purplish hue beneath: peduncles usually longer than petioles; corolla 1½–2 in. long, purple outside, the upper lip divided more than one-half; bractlets narrow, about half as long as ovary. B.R. 712. B.M. 3316. L.B.C. 11:1037. Var. **Halliàna,** Nichols. (*L. flexuòsa Halliàna*, Dipp. *Caprifòlium Halliànum*, Hort. *L. Halliàna*, Hort.) Of vigorous growth: lvs. usually pubescent on both sides when young, oblong-ovate, acute, to 2½ in. long: fls. short-peduncled, white, changing to yellow; tube as long as limb; bractlets broad, half as long as ovary. The type of the species seems to differ from this variety only in having the fls. purplish outside. A.G. 12:663. Gng. 3:293.

36. **longiflòra,** DC. Climbing shrub, glabrous, evergreen: lvs. oblong-lanceolate, shining above, pale beneath, 2–2½ in. long: fls. in short-peduncled pairs, sometimes crowded toward the end of branches; corolla white, changing to yellow, fragrant, 3-4 in. long, with very slender tube; bracts small, subulate: fr. white. S. China. B.R. 1232 (as *Caprifolium longiflorum*).—Tender. Intro. 1900, by Franceschi.



2205. Lonicera sempervirens. (×½)

37. **Hildebrandiàna,** Coll. & Hemsl. Climbing shrub, glabrous, evergreen: lvs. broadly ovate or elliptic-ovate, abruptly pointed, 4–6 in. long: fls. on stout peduncles; corolla 5–7 in. long, glabrous outside, yellow at first, changing to orange-red, with long and slender tube. Summer. Upper Burma. G.C. III. 24:219. B.M. 7677.—This has the largest fls. of any species, but is not hardy N.

Subgenus PERCLYMENUM (*Caprifòlium*).

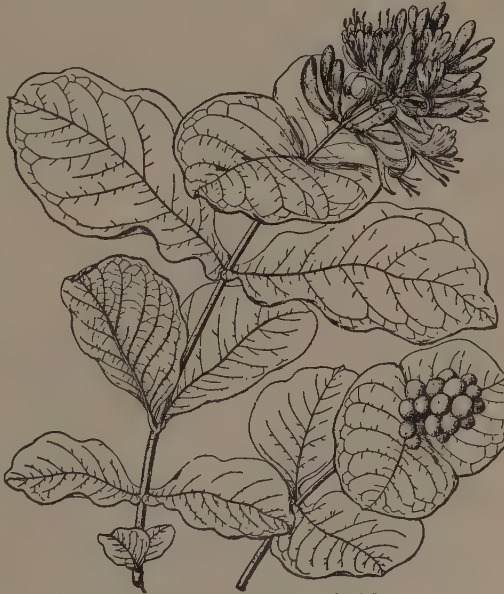
38. **sempérvirens,** Linn. (*Caprifòlium sempérvirens,* Michx.). Trumpet Honeysuckle. Fig. 2205. High-climbing, glabrous: evergreen southward: lvs. oval to oblong, glaucous beneath, the upper connate, 2–3 in. long: fls. in peduncled interrupted spikes; corolla with almost equal limb; tube slightly ventricose, glabrous, 1½–2 in. long, scarlet or orange-scarlet, rarely yellow. May–Sept. Conn. to Fla., west to Neb. and Texas; farther north sometimes escaped from cult. B.M. 781. R.H. 1856:361. Gn. 45, p. 307. G.M. 54:724. Var. **sulphùrea,** Jacques (var. *flàva,* Regel. *L. flàva nòva,* Hort.). Fls. yellow. Gt. 2:38. Var. **supérba,** Regel (var. *speciòsa,* Carr.). Fls. more brilliant scarlet. F.S. 11:1128. Sometimes cult. as *L. Magnevillea,* a name also applied to *L. dioica,* and to *L. Caprifolium* var. *pauciflora.* Var. **minor,** Ait. Lvs. oblong or narrow-oblong: fls. more slender, orange-red or orange-scarlet. Very free-flowering, but more tender. B.M. 1753. B.R. 556. Gn. 34:300.

39. **cilidsa,** Poir. Low sarmentose shrub: lvs. petioled, ovate or oval, glaucous beneath, glabrous but ciliate, the upper connate, 2–4 in. long: fls. in short-peduncled heads of 1 or few whorls; corolla slightly 2-lipped, with ventricose-gibbous tube, yellow to orange-scarlet, usually hirsute outside, 1¼–1¾ in. long. June, July. Brit. Col. to Calif. and Ariz. Var. **occidentàlis,** Nichols. (*L. occidentàlis,* Hook.). Fls. larger, glabrous outside, more brightly colored. B.R. 1457.

40. **Brównii,** Carr. (*L. sempérvirens Brównii,* André. *L. etrúsca* var. *Brównii,* Regel). Probably hybrid of *L. sempervirens* with *L. hirsuta.* Lvs. oval to oblong, glaucous beneath, the upper connate, glabrous: fls. in peduncled heads, orange-scarlet, scentless; tube gibbous at the base, longer than limb. Of garden origin. Gt. 2:38. F.S. 11:1133. Var. **plantierénsis,** Rehd. (*L. plantierénsis,* André). Fls. larger, more orange-colored and less deeply 2-lipped. I.H. 18:86. F.W. 1872:289. Var. **fuchsioìdes,** Rehd. (*L. fuchsioìdes,* Hort., not Hemsl.). Similar to *L. sempervirens,* but fls. 2-lipped, scarlet outside. G.F. 9:496. G.W. 5, p. 159. Var. **punícea,** Rehd. (*L. sempérvirens* var. *punícea,* Dipp.). Less vigorous: corolla orange-red.

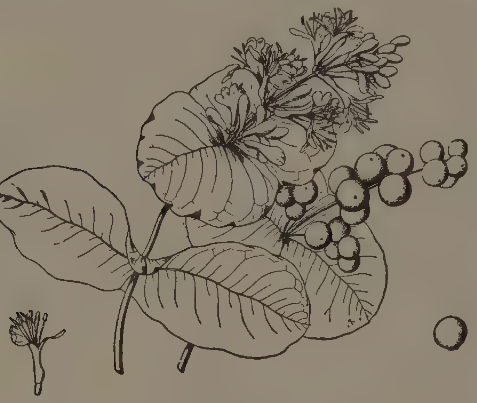
41. **hispídula,** Douglas. Bushy shrub with sarmentose branches, rarely twining, usually hirsute: lvs. oval to ovate, rounded or cordate at the base, often with foliaceous stipules, the upper connate or sometimes distinct, usually small, rarely to 2½ in. long, ciliate and pubescent, rarely glabrous: fls. in slender-peduncled and often panicled spikes, pink or yellowish, glabrous or hirsute, ⅓–½in. long, with short gibbous tube. June, July. Brit. Col. to Calif. B.R. 1761. Var. **vacíllans,** Gray (*L. califórnica,* Torr. & Gray. *L. hispídula* var. *califórnica,* Rehd.). Of more vigorous growth, with large lvs. to 3 in. long: corolla glandular-pubescent outside. Calif.

42. **hirsùta,** Eaton (*Caprifòlium pubéscens,* Goldie). Fig. 2206. High-climbing, with usually hirsute branchlets: lvs. petioled, broadly oval or ovate, obtuse, the upper connate and abruptly pointed, dark green above, pubescent on both sides when young, 2–4 in. long: fls. in short, mostly peduncled spikes, scentless, bright or orange-yellow, pubescent without, about 1 in. long, with the tube gibbous at the base; ovary and bractlets usually glandular. June, July. Vt. to Manitoba, south to Pa. and Ohio. B.M. 3103. Gn. 45, p. 307. B.B. (ed. 2) 3: 278. G.F. 9:344. (adapted in Fig. 2206).



2206. Lonicera hirsuta. (×½)

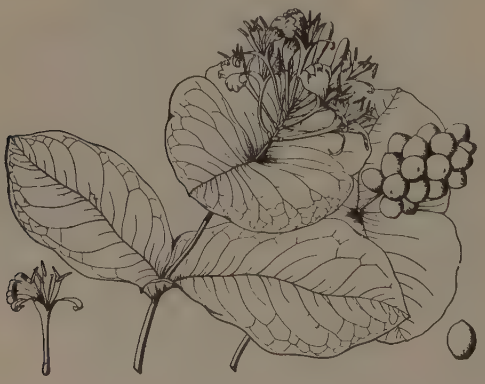
43. glaucéscens, Rydb. (*L. Doúglasii,* Koehne, not DC., nor Koch. *L. parviflòra* var. *Doúglasii,* Gray, partly). Climbing: branchlets glabrous: lvs. short-petioled or almost sessile, the upper connate, oval to obovate, glabrous above, pubescent beneath, 1½–3 in. long: fls. in short, almost sessile spikes; corolla yellow, mostly reddish outside and hairy, ¾–1 in. long; tube gibbous, longer than the limb; ovary and bractlets glabrous. May, June; fr. in Sept., Oct. Ont. to the Sask., south to Pa. and Neb. B.B. (ed. 2) 3:279.



2207. Lonicera prolifera. (×½)

44. dioìca, Linn. (*L. glaùca,* Hill. *L. mèdia,* Murr. *L. parviflòra,* Lam.). Usually shrubby, with slender, sarmentose branches, rarely climbing, glabrous: lvs. short-petioled or almost sessile, the upper connate, oval to oblong, obtuse, with usually undulate and transparent margin, very glaucous beneath, 1½–3 in. long: fls. in sessile or short-stalked spikes, greenish or whitish yellow, often tinged purplish, glabrous outside, ½–¾in. long, the tube gibbous, about as long as limb. May, June; fr. in Sept., Oct. Que. to Manitoba, south to Ohio and N. C. B.R. 138.

45. prolífera, Rehd. (*L. Sullivántii,* Gray. *Caprifòlium proliferum,* Kirchn.). Fig. 2207. Climbing about 4–5 ft., very glaucous: lvs. oval or obovate, the upper connate into a large disk, becoming thickish and very glaucous above, often finely pubescent beneath, 2–4 in. long: fls. in short-stalked or almost sessile spikes; corolla pale yellow, often marked purplish outside, about 1 in. long; tube gibbous, only little longer than limb. May, June; fr. in Sept., Oct. Ont. to Manitoba, south to Tenn. R.H. 1856:221 (as *L. flava*). G.F. 3:191 (adapted in Fig. 2207). Gn. 60, p. 285.—Very handsome in fall with the abundant scarlet berries.

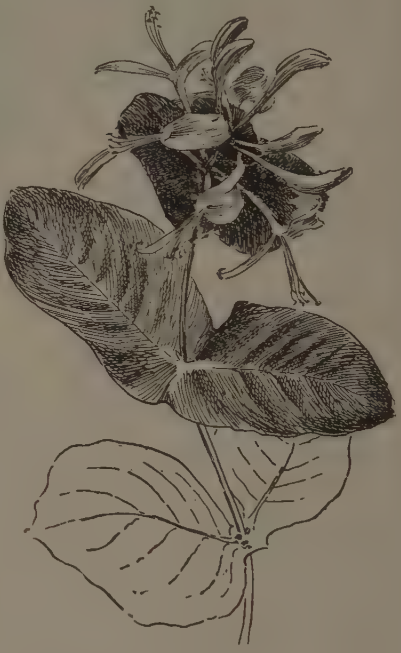


2208. Lonicera flava. (×½)

46. flàva, Sims (*Caprifòlium Fràseri,* Pursh). Fig. 2208. Climbing to 10 ft.: lvs. broadly oval to elliptic, the upper connate, bright green above, glaucous beneath, glabrous, 1½–3 in.: fls. in a peduncled head, bright or orange-yellow, fragrant, 1–1¼ in. long; tube slender, longer than limb. April, May. N. C. to Ky., Ga. and Ala. B.M. 1318. L.B.C. 4:338. G.F. 3:190 (adapted in Fig. 2208). Gn. 45, p. 307.—This species is rare in cult. and usually the preceding is cult. under this name.

47. impléxa, Ait. Much-branched, but less high-climbing, evergreen: lvs. oval to oblong-lanceolate, sessile, the upper connate into an elliptic, acute or mucronate disk, glaucous, glabrous 1–2 in. long: fls. in several whorls, each in the axils of connate lvs., scentless, yellowish white; tube slightly hairy within; limb rather short; stamens slightly exceeding the mouth. May, June. S. Eu., N. Afr. B.M. 640.

48. Caprifòlium, Linn. (*Caprifòlium horténse,* Lam. *C. perfoliàtum,* Roehl. *L. pállida,* Host). Fig. 2209. Climbing: lvs. oval to oblong, the upper connate into a roundish cup, almost glabrous, 2–4 in. long: whorls usually 2 or 3, each in the axils of connate lvs.: fls. yellowish white, often slightly purplish outside and slightly hairy, to 2 in. long, fragrant; bractlets very small or none. May, June. Cent. Eu. to W. Asia. B.B. (ed. 2) 3:278. H.W. 3, p. 129.—Sometimes escaped from cult. Var. **álba,** Ait. (*L. præcox,* Hort.). Fls. white. Var. **pauciflòra,** Carr. (*L. Caprifòlium rùbra,* Tausch, not Weston). Fls. purple outside.



2209. Lonicera Caprifolium. (×½)

49. americàna, Koch (*Periclýmenum americànum,* Mill. *L. itálica,* Schmidt. *L. etrúsca,* Hort. *L. Caprifòlium,* Auth.). Climbing: lvs. broadly oval to oblong-obovate, the upper connate, glabrous, 2–4 in. long; the upper whorls without connate lvs. at the base, somewhat crowded: fls. yellowish, usually purple outside and glabrous, fragrant, to 2 in. long; bractlets about half as long as ovary, smaller on the upper fls. June–Aug. Probably hybrid of *L. etrusca* and *L. Caprifolium,* much cult., mostly under the name of the latter, and sometimes escaped from cult. Gn. 45, p. 307 (as *L. etrusca* and *L. Caprifolium*); 54, p. 26. F.S. 11:1120 (as *L. Caprifolium major*). Var. **rubélla,** Rehd. (*L. Caprifòlium* var. *rubélla,* Tausch). Fls. purple outside. Var. **atrosanguínea,** Rehd. (*L. atrosanguínea,* Carr.). Fls. dark purple outside.

50. Heckróttii, Rehd. Only partially climbing: lvs. elliptic or oblong-elliptic, acute, almost sessile, the upper pairs connate, glaucous beneath, glabrous, about 2 in. long: fls. in peduncled spikes with few somewhat remote whorls, purple outside and sparingly glandular, 1½–2 in. long; bractlets about half as long as ovary. June–Sept.—Origin unknown, probably garden hybrid of *L. americana* and *L. sempervirens*. One of the most free-flowering of all climbing honeysuckles.

51. **tragophýlla**, Hemsl. High-climbing: lvs. short-petioled, oblong, rarely oval, obtuse or acute, bright green above, whitish beneath and pubescent at least along the midrib, 2–5 in. long: fls. in short-peduncled heads with usually only 1 or 2 whorls; bracts about one-third as long as ovary; corolla 3 in. long, yellow, glabrous, tube about 3 times as long as limb, sparingly pubescent inside. June. W. China. B.M. 8064. S.T.S. 1:46. G.C. III. 36:150. J.H.S. 28, p. 63. G. 28:289; 35:345. R.B. 32:261.—Has proved hardy as far north as Mass.

52. **etrúsca**, Santi. Climbing: lvs. broadly oval to obovate, usually obtuse, the upper ones connate into an oval obtuse disk, rarely distinct, 1–3 in. long, glabrous or pubescent: fl.-heads dense, long-peduncled, often in 3's; corolla yellowish white, usually tinged red, fragrant, 1½–2 in. long, with very slender tube. May–July. Distributed through the whole Medit. region in many different forms. Var. **pubéscens**, Dipp. (*L. gigantèa*, Zabel. *L. etrúsca gigantèa*, Zabel). Lvs. soft-pubescent on both sides, large. Var. **supérba**, Wright (*L. gigantèa*, Carr.). Lvs. large, about 2½ in. long, glabrous: fls. creamy yellow at first, finally almost orange. B M. 7977. Probably not different from var. *glabra*, Lowe.

53. **Periclýmenum**, Linn. (*Caprifòlium Periclýmenum*, Roem. & Schult.). WOODBINE. Fig. 2210. Climbing several feet high: lvs. all distinct, ovate to oblong-ovate, acute, 1½–3 in. long, dark green above, pale or glaucous beneath and sometimes sparingly pubescent: fls. in a peduncled dense head, very fragrant, yellowish white, usually carmine or purple outside and glandular pubescent, 1½–2 in. long. June–Sept. Eu., N. Afr., W. Asia. H.W. 3, p. 129. G.M. 45:615; 56:974. Var. **aùrea**, Lind. & André. Lvs. yellow or yellowish, particularly while young. I.H. 18:59. Var. **quércina**, Weston (var. *quercifòlia*, Ait.). Lvs. sinuately lobed and often with a narrow whitish margin. Var. **bélgica**, Ait. Glabrous: lvs. thickish, whitish beneath: fls. pale purple outside. Var. **serótina**, Ait. (*L. semperflòrens*, Hort.). Similar to the preceding: fls. dark purple outside, fading to pale purple, blooming late and profusely. Gn. 45:307.

2210. Lonicera Periclymenum. (×⅓)

L. affinis, Hook. & Arn. Allied to L. japonica. Lvs. ovate, pubescent or glabrous beneath, 2–3½ in.: fls. white at first, turning to deep yellow; bracts subulate; very free-flowering. China, Japan.—*L. alseuosmoìdes*, Graebn. Allied to L. Henryi. Branchlets glabrous: lvs. lanceolate or narrow-lanceolate, narrowed at base: fls. slightly over ½in. long, orange-red. W. China.—*L. Altmannii*, Regel & Schmalh. (L. tenuiflora, Regel & Winkl.). Allied to L. hispida. Shrub, to 6 ft.: branchlets pilose: lvs. broadly ovate to ovate-elliptic, pubescent below, ¾–2 in. long: bracts ovate-lanceolate; corolla 2-lipped, whitish, ½–¾in. long: fr. ovoid, scarlet. Turkestan. Var. *pilosiúscula*, Rehd. Lvs. only sparingly pilose on both sides. Hardy and handsome in fr.—*L. angustifòlia*, Wall. Allied to L. thibetica. Erect shrub, to 10 ft.: lvs. lanceolate, pubescent below when young, 1–2 in. long: fls. long-peduncled, white, fragrant, with regular 5-lobed limb. Himalayas. F.S. 4, pp. 407, 408 *b*. Tender.—*L arbòrea*, Boiss. Allied to L. Maackii. Erect shrub or small tree, to 30 ft.: lvs. roundish ovate, pubescent, ¾–1½ in. long.: fls. short-peduncled, 2-lipped, pinkish, small: fr. whitish. Spain. Var. *pérsica*, Rehd. (L. nummularia, Fisch. & Mey. L. nummulariifolia, Jaub & Spach). Lvs. smaller, less pubescent: corolla-tube not gibbous. W. Asia to Afghanistan.—*L. arizónica*, Rehd. Allied to L. ciliosa: lvs. slender-petioled, 1–1¾ in. long: limb of corolla nearly equal; tube slender; style glabrous. Ariz. S.T.S. 1:23.—*L. biflòra*, Desf. (L. canescens, Schousb.). Allied to L. japonica. Climbing, grayish tomentose: lvs. ovate, small: fls. in pairs, white, 2-lipped, with slender, long tube, fragrant; bracts subulate. Spain, N. Afr.—*L. cæruléscens*, Dipp.=L. xylosteoides.—*L. canéscens*, Schousb.=L. biflora.—*L. Chamíssoi*, Bunge. Allied to L. orientalis: lvs. very short-stalked, oval or ovate, glabrous, 1–2 in. long: peduncles ¼–½ in. long: fr. red. N. E. Asia.—*L. confùsa*, DC. Closely allied to L. biflora, but fls. and lvs. somewhat larger and ovary glabrous. Japan, China. B.R. 70 (as L. japonica). Gn. 45, p. 307. Has been often confounded with L. japonica, but is easily distinguished by the small subulate bracts.—*L. conjugiàlis*, Kellogg. Allied to L. orientalis. Erect shrub: lvs. oval or ovate, pubescent: fls. slender-peduncled, small, 2-lipped, dark purple: fr. red. Wash. to Calif.—*L. decípiens*, Hook. f. and Thoms.=L. lanceolata.—*L. deflexícalyx*, Batalin. Allied to L. trichosantha. Upright shrub, to 15 ft.: lvs. lanceolate, acuminate, pubescent on both sides, 1½–3 in. long: fls. slightly over ½in. long: fr. orange-red. W. China. B.M. 8536.—*L. Delavàyi*, Franch.=L. similis var. Delavayi.—*L. depréssa*, Royle=L. Myrtillus var. depressa.—*L. díscolor*, Lindl. (L. orientalis var. discolor, Clarke). Allied to L. orientalis. Lvs. ovate to ovate-oblong, glaucous and glabrous beneath: peduncles ½–1 in. long: fls. yellowish white, slightly pinkish. Himalayas. B.R. 33.44.—*L. diversifòlia*, Wall.=L. quinquelocularis.—*L. Ferdinandii*, Franch. Allied to L. iberica. Lvs. ovate to ovate-lanceolate, acuminate, sparingly hairy, 1–2¼ in. long, often with stipules: fls. short-peduncled, ¾in. long, yellow, appressed setose outside. N. W. and Cent. China. Var. *leycesterioìdes*, Zabel (var. Beissneriana, Zabel). Less hairy: lvs. larger, to 7 in. long: corolla less setose. Only the variety is in cult.—*L. floribúnda*, Boiss. & Buhse. Allied to Korolkovii. Lvs. broadly ovate to elliptic, obtuse: peduncles ½–⅕in., decreasing in length toward the end of the branchlets; bractlets nearly as long as ovaries. Persia. Not in cult.; the plant cult. under this name is L. Korolkovii.—*L. Giráldii*, Rehd. Allied to L. Henryi. Climbing: branchlets with fulvous spreading hairs: lvs. oblong-lanceolate, hairy on both sides, 1½–2¼ in. long: fls. crowded at the end of the branchlets, ¾in. long, densely covered with spreading yellowish hairs. W. China. B.M. 8236. R.H. 1907, p. 299.—*L. Gríffithii*, Hook. f. & Thoms. Allied to L. Periclymenum. Lvs. broadly ovate to ovate-oblong, the pair below the infl. nearly suborbicular: whorls of fls. 2–3, each subtended by a cupula. Afghanistan. S.T.S. 1:24.—*L. gynochlamýdea*, Hemsl. Allied to L. pileata. Upright shrub: lvs. deciduous, lanceolate, acuminate, nearly glabrous, 2–4 in. long: fls. short-peduncled, 2-lipped, ⅓–½in. long, whitish, flushed pink: fr. red. W. China.—*L. heterophýlla*, Decne. Allied to L. alpigena. Lvs. elliptic to oblong. lanceolate, sometimes irregularly lobed, acuminate, glabrous, 1¾–3½ in. long: corolla yellowish white, flushed red: fr. distinct. Afghanistan, Turkestan. Var. *Karelínii*, Rehd. (L. Karelini, Bunge). Lvs. not lobed, glandular along the midrib: corolla usually glandular outside. Cent. Asia. Only the variety is sometimes cult.; hardy.—*L. Karelíni*, Bunge=L. heterophylla var. Karelinii.—*L. Koehneàna*, Rehd. Allied to L. chrysantha. Lvs. ovate, rhombic-ovate to obovate, acuminate, soft-pubescent beneath, 1–4 in. long: peduncles ½–1 in. long; bractlets connate into pairs, half as long as the pubescent ovary: fr. dark red. W. China. S. T. S. 1:21.—*L. lanceolàta*, Wall. (L. decipiens, Hook. f. & Thoms.). Allied to L. orientalis. Lvs. ovate to ovate-lanceolate, acuminate, grayish green and pubescent beneath, particularly on the veins, 2–4 in. long: peduncle ½in. long; bractlets at least half as long as ovaries: fr. black, connate only at the base. Himalayas—*L. leycesterioìdes*, Graebn.=L. Ferdinandii var. leycesterioides.—*L. Maximòwiczii*, Maxim. Allied to L. orientalis. Shrub, to 6 ft.: lvs. oblong-elliptic: fls. peduncled, purplish violet, 2-lipped, rather small: frs. connate, red. N. E. Asia. Gt. 17:597.—*L. micrántha*, Dipp.=L. xylosteoides.—*L. micranthoìdes*, Zabel (L. nigra × L. tatarica). Similar to the latter: fls. small, reddish white; bractlets half as long or as long as ovary; stamens pubescent: fr. red. Garden origin.—*L. microphýlla*, Willd. Allied to L. tangutica. Erect shrub, to 4 ft.: lvs. oval, about ½in. long: fls. slender-peduncled, 2-lipped, yellowish white, small: berries connate, orange-red Altai to Himalayas.—*L. mucronàta*, Rehd. Allied to L. fragrantissima. Lvs. broadly oval to obovate, mucronate, ½–1 in. long: fls. short-stalked, white, fragrant: frs. connate, red. W. China. S.T.S. 2:122.—*L. mupinénsis*, Rehd. Allied to L. alpigena. Bud-scales upright, lanceolate, persistent: lvs. oblong, acuminate, sparingly pilose beneath: fls. dark purple: frs. distinct, red. W China.—*L. myrtilloìdes*, Purpus. Allied to L. syringantha. Lvs. elliptic to oblong-ovate, acute, ½–1⅓ in. long: peduncles ½in. long; fls. pinkish white, ⅓in. long, fragrant: frs. connate, red. Origin unknown.—*L. Myrtíllus*, Hook. & Thoms. (L. parvifolia var. Myrtillus, Clarke). Allied to L. syringantha. Lvs. oval, obovate or oblong, ¼–1 in. long: fls. short-stalked; bracts narrow-oblong; corolla tubular-campanulate, ⅓in. long, yellowish white: fr. red, connate. Himalayas. S.T.S. 1:44. Var. *depréssa*, Rehd. (L. depressa, Royle. L. parvifolia, Hook. f. & Thoms.). Fls. slender-stalked; bracts broader, usually oval.—*L. nepalénsis*, Kirchn.=L. xylosteoides.—*L. nervòsa*, Maxim. Allied to L. orientalis. Shrub, to 10 ft., with slender dark purple branchlets: lvs. ovate, with purple veins, 1–2 in. long: fls. small, pink, long-peduncled, 2-lipped: fr. black, connate only at base China. Hardy, graceful shrub.—*L. nìgra*, Linn. Allied to the preceding species. Shrub, to 5 ft.: lvs. elliptic to elliptic-lanceolate, 1½–

2½ in. long: fls. slender-peduncled, pink, small: fr. black. Mountains of Cent. Eu. H.W. 3, p. 128.—*L. nummulària*, Fisch. & Mey., and *L. nummulariifòlia*, Jaub. & Spach=L. arborea var. persica.—*L. obovàta*, Royle. Allied to L. tangutica. Lvs. very small, obovate: fls. small, yellowish white, gibbous, short-stalked: frs. connate, bluish black. Himalayas.—*L. Ólgæ*, Regel & Schmalh. Allied to L. hispida. Lvs. ovate to lanceolate, acute, ½–2⅓ in. long: fls. short-stalked, upright, 2-lipped, over ½in. long: fr. bright red, distinct. Turkestan.—*L. parvifòlia*, Hook. f. & Thoms.=L. Myrtillus var. depressa.—*L. pérsica*, Jaub. & Spach= L. arborea var. persica.—*L. propínqua*, Zabel (L. alpigena × L. Ledebourii). An interesting hybrid, in one form more like the first, in the other more like the second parent. Of garden origin.—*L. prostràta*, Rehd. Allied to L. trichosantha. Prostrate shrub: lvs. oval or ovate, acute, ½–1 in. long: fls. small: fr. bright red. W. China.—*L. purpuráscens*, Walp. Allied to L. tangutica. Branchlets pubescent: lvs. oval to oblong, pubescent, ¾–1¾ in. long: fls. tubular-funnelform, dull purple, hairy, over ½in. long, gibbous: fr. bluish black. Himalayas, Afghanistan.—*L. pyrenàica*, Linn. Allied to L. canadensis. Glabrous: lvs. cuneate-oblong: fls. slender-peduncled, tubular-campanulate, regularly 5-lobed, white, ¾in. long: frs. red, distinct. Pyrenees Mts. B.M. 7774.—*L. quinquelocularis*, Hardw. (L. diversifolia, Wall.). Allied to L. Maackii. Lvs. ovate or elliptic to oblong-ovate, narrowed or rounded at base, pubescent, 1¼–2¾ in. long: fls. short-stalked; corolla ¾in. long, with slender tube, pale yellow: fr. white. Himalayas, Afghanistan. H.I. 9:807. Var. *translùcens*, Zabel (L. translucens, Carr. L. diversifolia, Dipp.). Lvs. rounded or subcordate at base: tube gibbous, much shorter than limb. B.R. 30:33.—*L. ramosíssima*, Franch. & Sav. Allied to L. tangutica. Lvs. oval to ovate, pubescent, ½–1 in.: fls. long-peduncled, yellowish; bractlets connate, as long as ovaries: fr. scarlet. Japan. Very handsome in fr.—*L. retùsa*, Franch. Allied to L. orientalis. About 6 ft. high: lvs. obovate or broadly ovate, bluish white beneath: fls. in pairs, white, becoming yellowish: fr. shining black. W. China. S. T. S. 2:123.—*L. rupícola*, Hook. f. & Thoms. Allied to L. thibetica. Lvs. ovate to oblong, obtuse or acutish, dull bluish green above, glabrous or pubescent beneath, ½–1 in. long: fls. pubescent outside, pale purple. Himalayas.—*L. saccàta*, Rehd. Allied to L. tangutica. Lvs. elliptic-oblong to oblong, obtusish, pubescent beneath, ¾–2 in. long: fls. long-peduncled; bracts narrow-oblong, leafy; tube gibbous at base. Cent. and W. China. S.T.S. 1:20.—*L. segreziénsis*, Lav. Similar to L. Xylosteum: lvs. more pubescent, dark bluish green: fls. short-peduncled, yellowish: fr. dark red. Of garden origin. Supposed to be a hybrid of L. quinquelocularis and L. Xylosteum.—*L. símilis*, Hemsl. Allied to L. japonica. Plant pilose: lvs. ovate-oblong to lanceolate, ciliate, white-tomentose below, 1¾–3½ in. long: fls. slender-peduncled, 2 in. long, white; bracts subulate. Cent. and W. China. Var. *Delavàyi*, Rehd. (L. Delavayi, Franch.). Glabrous, but lvs. tomentose beneath and sometimes slightly ciliate. Only this variety is in cult.—*L. spléndida*, Boiss. Allied to L. implexa and L. etrusca: glabrous, glaucous: fls. in a many-fld., sessile head, yellowish white, tinged purple. Spain. F.S. 11:1130. Gt. 39, p. 65.—*L. strophióphora*, Franch. Allied to L. hispida. Winter-buds with several scales: lvs. short-stalked, ovate, sparingly hirsute, 2–3½ in. long: fls. funnelform, white, nearly ¾in. long, with the lvs.: fr. red, distinct. Japan.—*L. subæquàlis*, Rehd. Allied to L. ciliosa. Lvs. elliptic to obovate-oblong, glabrous, 2–5 in. long: fls. funnelform with nearly regular limb; usually only 1 sessile whorl. W. China.—*L. tenuiflòra*, Regel & Winkl.=L. Altmannii.—*L. tomentélla*, Hook. f. & Thoms. Allied to L. thibetica. Erect shrub, to 12 ft.: lvs. small, ovate to oblong, pubescent: fls. short-peduncled, nodding, small, regular, white: fr. connate, black. Himalayas. B.M. 6486. Tender.—*L. translùcens*, Hort.=L. quinquelocularis. —*L. Tschonóskii*, Maxim. Allied to L. orientalis. Lvs. elliptic-oblong, acute at both ends, quite glabrous 2–4 in. long: fls. long-stalked, pinkish; bractlets connate, about half as long as ovaries: fr. nearly distinct, red. Japan.—*L. utahénsis*, Wats. Closely related to L. canadensis. Lvs. broadly ovate to oblong, obtuse, not ciliate: corolla smaller, less gibbous. Brit. Col. to Ore., Utah, Wyo.—*L. Vidàlii*, Franch. & Sav. Allied to L. alpigena. Lvs. ovate or elliptic, abruptly acuminate, pubescent, 1½–3 in. long: fls. lilac, on glandular peduncles about ½in. long; bractlets connate, one-half or three-fourths as high as ovaries: fr. red, partly connate.—*L. Vilmòrinii*, Rehd. A garden hybrid between L. deflexicalyx and L. quinquelocularis—*L. Webbiàna*, Wall. Allied to L. alpigena. Lvs. larger, acuminate, pubescent: fls. paler; ovaries separate. Himalayas. S.T.S. 1:69.—*L. xylosteoìdes*, Tausch. (L. tatarica × L. xylosteum. L. micrantha, Dipp., not Regel. L. cærulescens, Dipp. L. nepalensis, Kirchn.). Lvs. usually rhombic-ovate, broadly cuneate at base, bluish green, slightly pubescent: corolla small, pinkish: fr. red. Garden origin.

ALFRED REHDER.

LOOSESTRIFE: *Lysimachia* and *Lythrum.*

LOPÈZIA (after the Spaniard Lopez, who wrote on the natural history of the New World). *Onagràceæ.* Greenhouse plants grown for the attractive flowers; may be planted in the open far South.

Erect, branching, glabrous or pubescent: lvs. alternate or the lower opposite, dentate: fls. usually small, in leafy racemes or subcorymbose at the ends of branches, slender-pedicelled; calyx-limb 4-parted, unequal, deciduous, linear-lobed; petals 4, short- or long-clawed, unequal, the posterior ones narrower, the claws glandular at the apex; stamens 2, attached to the pistil, one anther-bearing, the other petal-like; ovary 4-celled: caps. globose, leathery; seeds obovoid, with a leathery granulated coat.—Species a score or more, in Mex. and Cent. Amer. Little grown, but valuable for the gay forms and colors.

albiflòra, Schlecht. Fig. 2211. Suffruticose perennial, diffuse, 2 ft. high: young branches somewhat villous: lvs. cuneate at the base, ovate-lanceolate to ovate, irregularly serrate or remotely dentate, largest 1½ in. long: pedicels horizontally spreading, slender; petals white, often tinged slightly pinkish at base, larger ones obliquely spatulate, obtuse and mostly notched, smaller ones linear, obtuse, equaling or exceeding the sepals. Mex.

lineàta, Zucc. Shrubby, the st. and petiole usually hairy, 3 ft.: lvs. ovate, acute, crenate-serrate: fls. red, described as "insect-like," in terminal short racemes or clusters; posterior petals bearing a single gland. Mex. B.R. 26:40. G. C. III. 43:294.

2211. Lopezia albiflora. (×½)

miniàta, DC. Slender shrubby perennial, with terete sts. which are glabrous or with lines of hairs: lvs. small, ovate-oblong, serrate: fls. many, small, the petals red in lower part, and rose-color with violet margins in upper part; posterior petals with 2 glands; sepals spreading. Mex., Guatemala. —Probably confused with the last.

macrophýlla, Benth. Semi-shrubby perennial, with green and succulent branches: lvs. long-stalked, ovate-acuminate, serrate: fls. solitary on axillary peduncles, large, bright red. Mex., Guatemala. B.M. 4724. H.F. 1:48.

coronàta, Andr. Annual: lvs. scattered or in whorls, glossy, glabrous: 2 upper petals linear, bright lilac; 2 side ones larger; lamina roundish obovate, light lilac, with dark red mark at base. Mex. R.H. 1905, pp. 216, 217.—Cult. in S. Calif.

L. H. B.

LOPHÁNTHUS (Greek, *crested flower;* application not apparent). *Labiàtæ.* As defined by Briquet in Engler and Prantl's "Natürlichen Pflanzenfamilien," this genus comprises 2 Asian species. They are erect herbs with dentate lvs. and axillary clusters of blue or bluish fls. *L. chinénsis*, Benth. (*Hyssópus Lophánthus*, Linn.), from N. China and Siberia is sometimes planted, although apparently not in the trade. It is a nepeta-like plant, 1–1½ ft. high, with aromatic foliage, ovate lvs., and blue fls. in 3–5-fld. cyme-clusters: blooms midsummer to autumn, and useful in the alpine garden.

The few N. American species formerly held under this name are now included under Agastache. Two of them have been offered by dealers in native plants, but they are scarcely horticultural subjects, although useful for the wild garden. These are: **Agástache Fœniculum,** Kuntze (*L. anisàtus*, Benth.). GIANT HYSSOP. Height 2–5 ft.: lvs. ovate, anise-scented when crushed, white beneath: fls. blue; calyx-teeth tinged purple or violet. July, Aug. Prairies, Wis., to Rockies. **A. scrophulariæfòlia,** Kuntze (*L. scrophulariæfòlius*, Benth.). Height 4–6 ft.: lvs. not anise-scented, not white beneath: fls. dull purplish; calyx-teeth whitish. Borders of thickets, N. Y. to Wis. and N. C.

L. H. B.

LOPHOCÁRPUS: *Lonchocarpus.*

LOPHOCÈREUS (*crest* and *Cereus*). *Cactàceæ.* Stout plants growing in clusters, with few ribs. Areoles on lower part of st. very different from the upper ones; flowering areoles bearing long, bristle-like hairs standing at right angles to the st.: fls. several from each areole, small: fr. small, red.—Three species have been described.

Schóttii, Brit. & Rose (*Pilocèreus Schóttii,* Lem.). Branching from the base, 10–15 ft. high, glaucous: ribs 4–10, commonly 5; spines 4–7, very short, thickened at base; areoles of the fruiting area bearing very copious and long (1–3 in.) stiffish twisted bristles: fls. small, pinkish, about 1 in. long: fr. soft, edible, the size and somewhat the color of an olive. N. W. Mex. and Low. Calif.

L. Sargentiànus, Brit. & Rose, (G.F. 4:437), and *L. austràlis,* Brit. & Rose, are occasionally seen in cult.

J. N. Rose.

LOPHÓPHORA (Greek, *crest-bearing*). *Cactàceæ.* Depressed globose, often proliferous and cespitose, unarmed except in seedling forms; tubercles conical, bearing at summit the flowering areole filled with white hairs: fls. from the center of the plant, small, pinkish: fr. clavate, naked, pinkish; seeds black. A very distinct genus, sometimes referred to Anhalonium and at other times to Echinocactus. Under the latter genus it was described in Cyclo. Amer. Hort.

Wílliamsii, Coult. (*Echinocáctus Wílliamsii,* Lem. *Anhalònium Wílliamsii,* Lem. *E. Lewínii,* Schum. *Anhalònium Lewínii,* Hennings. *L. Lewínii,* Thomp.). Hemispherical, from a very thick root, often densely proliferous, transversely lined below by the remains of withered tubercles: ribs usually 8 (in young specimens often 6), very broad, gradually merging above into the distinct nascent tubercles, which are crowned with somewhat delicate penicillate tufts, which become rather inconspicuous pulvilli on the ribs: fls. small, whitish to rose. Texas and Mex.—The well-known "mescal button," used by the Indians in religious rites. Other Indian vernacular names are: peyotl, peyote, pellote, xicori, hicori, hiculi, huatari, camaba, señi (Kiowa Indians), ho (Apaches), wokowi (Comanches), mescal-buttons, mezcal-buttons (Oklahoma, Texas), teonanacatl (Ancient Aztecs).—This plant is highly esteemed and even held in superstitious reverence by several tribes of Indians in the mountains of Mex. and in the U. S., on account of its narcotic properties. It is said that it produces beautiful highly colored visions. Its taste is bitter and disagreeable, and it sometimes causes vomiting. The use of the drug is accompanied by the loss of a sense of time. Its effects have been compared to those of hasheesh (*Cannabis indica*), but that narcotic produces delusions of merriment while lophophora causes a condition of ideal content followed by wakefulness. Several alkaloids have been separated from it, among them lophorine, anhalonine, and mezcaline. (See Dixon, W. E., Journ. Physiol., Sept., 1899, p. 71.) This plant was first received by wholesale druggists from Mrs. Anna B. Nickels, of Laredo, Texas, who called attention to the fact that the Indians of N. Mex. and S. W. U. S. "use the plant in manufacturing an intoxicating drink, also for breaking fevers" and that the tops cut off and dried are called mescal-buttons. These dried tops, which are often strung and sold in the markets of Mex., look very much like mushrooms and were mistaken for such by the early Spaniards. The Aztecs, who applied the name nanacatl to mushrooms in general, called this plant teonanacatl, which signifies "sacred mushroom," but they had very imperfect notions of botanical distinctions, and their name may be compared to "pine-apple," which is certainly far removed from an apple. Hubert Howe Bancroft mentions this narcotic as a mushroom, and for centuries investigators have sought in vain for a Mexican fungus causing the effects attributed to the teonanacatl. Its indentity, however, was for the first time established by W. E. Safford at a meeting of the Botanical Society of Washington, May 4, 1915. For an account of the history and ceremonial use of this plant, see Journal of Heredity, July, 1915.

J. N. Rose.
W. E. Safford.

LOPHOSPÉRMUM: *Maurandia.*

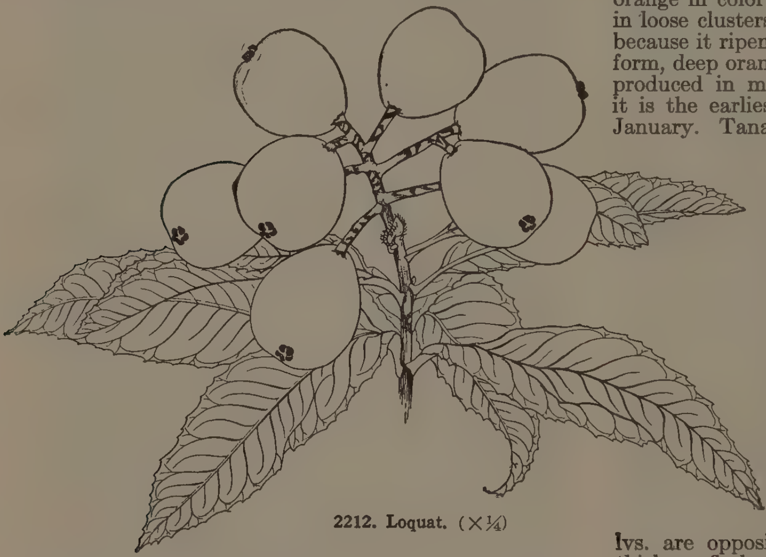
LOQUAT. Fig. 2212. The loquat, or biwa of the Japanese (*Eriobotrya japonica,* Lindl.), is a small evergreen fruit tree with handsome foliage, considered to be a native of China and Japan. It has long been cultivated in those countries as well as in northern India; within recent years it has become fairly common in the Mediterranean basin, especially in Algeria and Sicily, and in the milder sections of the United States. In Florida and the Gulf States it is seen in dooryards and gardens, but is rarely planted in orchard form; in California its cultivation is conducted commercially. It is also grown in some tropical regions, but does not succeed so well as in the subtropics. In Japan the annual production is said to be over 20,000,000 pounds.

The tree, which attains an ultimate height of about 25 feet, is more or less densely clothed with elliptical to oblong-obovate, nearly sessile, remotely toothed deep green leaves, varying from 6 to 10 inches or more in length. The small, white, very fragrant flowers, which are produced in fall, are borne in crowded woolly panicles 4 to 7 inches long. The fruit, which ripens in spring, varies in shape from spherical to pyriform, in color from pale yellow to deep orange, and in the best varieties is sometimes 3 inches in length. The skin is thin and smooth, but tougher than that of an apple. The flesh is firm and meaty in some varieties, more melting in others, almost white to salmon-orange in color, juicy, and of a sprightly flavor suggestive of a cherry. The seeds, which are about ¾inch long and dark brown in color, vary from one to eight or nine in number, four or five being common. They occupy a large amount of space in the center of the fruit, the reduction of the proportion of seed to flesh being one of the points most sought in breeding. The loquat is eaten while fresh, or is made into pies, jams, jellies, preserves and the like.

The tree is successful on a wide variety of soils, but has done best on clay loam. Ikeda, a Japanese authority, considers that the fruit reaches its highest degree of perfection when grown near the seacoast. For orchard-planting a piece of well-drained land should be chosen, and the trees set 20 to 24 feet apart. Their culture presents few difficulties; in fact the loquat will thrive and produce good crops with less care than many other fruit trees. It does not require a great amount of fertilizer on reasonably good soils, but leguminous cover-crops have been found highly beneficial. Occasional pruning is required to admit light to the center of the tree, and to keep the branches somewhat thinned out. To obtain fruit of good size and best commercial value, it may be desirable to thin the crop as soon as the young fruits have set, leaving no more in a cluster than the tree can properly mature. Picking for market should be done when the fruit has lost its acidity and is fully ripe; if picked too soon the loquat is quite sour. For jelly only acid fruit is used. When packed in boxes holding about thirty pounds, the fruit can be shipped successfully to nearby markets, but for distant markets smaller packages and great care in packing are necessary.

Pear blight (*Bacillus amylovorus*) and loquat scab (*Fusicladium eriobotryæ*) are at times troublesome in the California orchards, and a borer is reported from Japan which occasionally attacks the tree.

While in many countries the loquat is usually propagated from seed, there is as much variation among the seedlings as with other tree-fruits, and good varieties can be perpetuated only by some vegetative means of propagation. Both budding and grafting are practised, budding being the method preferred in the United States, and usually employed when trees are desired for commercial planting. Seedlings are often planted in dooryards, where they not only serve as admirable ornamental trees, but produce an abundance of reasonably good fruit. In budding and grafting, seedling loquats are generally used as stocks. When budded on quince, the tree is considerably dwarfed; this stock is sometimes used, however, because its fibrous root-system readily permits of transplanting. Seeds should be planted as soon as removed from the fruit, either singly in pots, or in flats from which they can be potted off later on. A light loam should be used, covering the seeds to a depth of about 1 inch. When the young plants have attained a height of 6 or 7 inches, they may be planted in nursery rows in the open ground, where they can be grown until the stems are about ½ inch in diameter at the base, when they are ready for budding. This is best done during October or November, depending upon climatic conditions. The buds are allowed to lie dormant until early spring, when they must be forced into growth. Budwood should be of young and smooth wood, preferably that which has turned brown and lost its pubescence, and from which the leaves have dropped. Shield-budding, essentially the same as practised with the citrous fruits, is the method commonly used. The buds should be cut somewhat larger than for the orange, preferably not less than 1½ inches in length. After inserting them in T-incisions made in the stocks at a convenient point not far above the ground, they should be tied with raffia, soft cotton string, or waxed tape, and left about three weeks, when they should have formed a union. At this time they may be unwrapped, and if necessary, rewrapped loosely, so as to allow the buds to start into growth. When not rewrapped, the bark sometimes opens up around the bud and exposes it to the air, causing its death. The stock must be cut back to a point about 3 inches above the bud, and all adventitious buds rubbed off as fast as they make their appearance. Difficulty is sometimes experienced in forcing the bud into growth.



2212. Loquat. (×¼)

In grafting, a simple cleft graft is used, with a cion of about the diameter of a lead pencil, and of well-matured wood.

Most of the named varieties of the loquat have originated in Japan, Algeria and California. Ikeda mentions forty-six varieties of Japanese origin, of which eight are recommended as the best for cultivation. Trabut of Algiers describes twelve varieties of Algerian origin, though none of them is considered so desirable, from a commercial standpoint, as Tanaka, with the possible exception of Taza, which resulted from a cross between Tanaka and one of the local forms. Tanaka is of Japanese origin, but has been grown in Algeria for several years, and also to a very limited extent in California, where it has not, however, become as popular as several varieties of local origin. Most of the varieties originated in the United States have been produced by C. P. Taft, of Orange, California, who has done more to improve the loquat than any other man. Among the best may be mentioned Advance, a bright yellow, pyriform fruit, sometimes 3 inches in length, produced in very large, compact clusters and ripening from March to June; Champagne, oval to pyriform, 2 to 3 inches in length, white-fleshed, produced in clusters as large as those of Advance but less compact, considered the best of all in flavor; Premier, oval, not quite so large as Advance, salmon-orange in color; Victor, a very large and showy fruit, in loose clusters, not considered valuable in California because it ripens late in the season; Early Red, a pyriform, deep orange-colored fruit, 1 to 2 inches in length, produced in medium-sized clusters, valuable because it is the earliest of all, commencing to ripen in late January. Tanaka is an attractive fruit of large size and deep orange-color, with unusually good shipping qualities, but it ripens too late to be of commercial value in California. The earliest fruits are the ones which yield the greatest returns, because they come into market at a time when fresh fruits are scarce.

F. W. Popenoe.

LORÁNTHUS (*strap-flower*, from the form of the petals). *Loranthàceæ*. Several hundred parasitic evergreen shrubs, mostly of tropics in many countries; one of the extensive mistletoe family. They are not horticultural subjects, but attempts are sometimes made to grow them, it is said with success, by sowing them on the exposed roots or branches of their hosts. The lvs. are opposite or alternate, entire, usually either thick or fleshy: fls. usually perfect, often showy, the 4–6 petals free or more or less joined to form a tubular corolla; calyx entire or 4–6-toothed; stamens as many as petals and attached on them: fr. a berry or drupe, with mucilaginous viscid contents. They are parasitic on upper parts of trees or shrubs or sometimes on the ground.

LOROPÉTALUM (Greek *loros*, strap, and *petalum*, alluding to the strap-shaped petals). *Hamamelidàceæ*. Ornamental shrubs grown chiefly for their white flowers, appearing in winter or early spring.

Evergreen, stellate-pubescent: lvs. alternate, short-petioled, entire, without stipules: fls. fascicled at the end of short branchlets, sessile; calyx short, 4-lobed; petals 4, linear; stamens 4, with very short filaments; ovary inferior, 2-celled: caps. woody, dehiscent, 2-seeded.—Two species in China.

Only *L. chinense* is in cultivation, a handsome much-branched shrub with rather small dull persistent foliage and clustered white or sometimes yellowish or greenish white feathery flowers in early spring. It will probably be hardy as far north as Washington, D. C. It is a desirable plant for the cool greenhouse and if grown in pots a peaty and sandy soil will suit it best. Even where the plant is hardy out-of-doors, the flowers are liable to be injured by frost. Propagation is by seeds, and probably by grafting on Hamamelis.

chinénse, Oliver (*Hamamèlis chinénsis*, R. Br.). Shrub, to 12 ft.: branchlets densely ferrugineous-pubescent: lvs. ovate to ovate-lanceolate, acuminate, rounded and oblique at the base, glaucescent below and hairy on the veins, ciliate, 1–2 in. long: fls. in clusters of 4–5; petals strap-shaped, ¾–1 in. long, white, yellowish or greenish white. March, April. Cent. and S. E. China. B.M. 7979. G. C. II. 19:152; III. 15:343. Gn. 65, p. 255. J.H. III. 18:235. R.H. 1904, p. 571. I.T. 2:58. G. 26:69.

Alfred Rehder.

LÒTUS (an old Greek name). *Leguminòsæ.* Herbs and subshrubs, grown for the yellow, purple, rose-colored or white flowers.

Plants glabrous, silky or hirsute: lvs. with 3–5 lfts. crowded at the apex of the petiole and commonly 2 joined to the st. and resembling stipules: fls. mostly pea-shaped, often in axillary few-fld. umbels, rarely solitary; standard broad, contracted at base; wings obovate; keel incurved or inflexed, beaked; calyx-lobes longer than the tube; stamens 9 and 1, connate but free from the petals: pod oblong or linear.—Species 80–100, largely in the Medit. region, but also in S. Afr., Temp. Asia and Austral. By some botanists, the genus Hosackia (which see) has been united with Lotus, but it differs in having usually more lfts., short calyx-teeth, obtùse keel. One lotus (*L. corniculatus*) has become established in N. Amer. *Lotus nigricans* of cult. is *Kennedya nigricans.*

Lotus meant several things to the ancients: (1) the Greek lotus, a leguminous plant on which horses fed. This was probably what we call to-day *Lotus corniculatus,* the common bird's-foot trefoil of temperate regions. (2) The Cyrenean lotus, an African shrub, the fruit of which was eaten by certain North African tribes who were called lotus-eaters. The fruit was said to be honey-sweet, the size of an olive and in taste like a date. This was probably *Zizyphus Lotus,* a prickly shrub whose fruit is, however, considered inferior to that of the common jujube, *Zizyphus sativa.* Other conjectures have been: *Celtis australis,* a tree which has a small, sweet berry; *Nitraria tridentata,* a thorny desert shrub whose succulent fruit has a stimulating quality, and *Rhamnus Lotus,* another North African plant. European lotus is a name for *Diospyros Lotus,* a kind of date plum which is cultivated in southern Europe, but the fruit is hardly edible. (3) The Egyptian lotus or sacred lily of the Nile. This is *Nymphæa Lotus,* which, like the Hindu lotus, has rose-colored as well as white flowers. American cultivators at the present time almost universally consider that the true Egyptian lotus is *Nelumbium speciosum,* now called *Nelumbo,* but *Nelumbium speciosum* is not a native of Egypt. (4) The Hindu and Chinese lotus, also called the sacred or Pythagorean bean. This is *Nelumbo indica,* better known as *Nelumbium speciosum.* The name lotus was doubtless used for other water-lilies, particularly the blue-flowered *Nymphæa cærulea.*

A. *Lvs. thread-like: fls. odd, scarcely pea-shaped.*

Bertholètii, Masf. (*L. peliorhýncus,* Hook. *L. pelyorénsis,* Hort.). Coral Gem. Small, much-branched, slender bush, with a silvery hue: lfts. whorled, 8–9 lines long: fls. 1½ in. long, in loose clusters of about 20 toward the end of the branches, short-pedicelled, scarlet or crimson fading to orange; standard recurved like a horn; keel acuminate, longer than the wings. Cape Verde, Canaries. B.M. 6733. R.H. 1895:308; 1914, p. 185. G. 25:255. G.L. 27:169.—Peliorhyncus means "bruised or discolored nose." This name, however, is apparently more recent than *L. Bertholetii.* Grown chiefly in hanging-baskets; in S. Calif. it is much used for sunny rockeries. Prop. by division or cuttings. The odd long-pointed fls. make this an interesting and showy species. Var. **atrococcíneus,** Hort., is an easily grown greenhouse plant for baskets, differing from the species in its darker-colored glossy deep scarlet black-spotted fls.

mascaénsis, Burch. A recent species from Teneriffe: similar to *L. Bertholetii* in foliage, but more compact and bushy, with shorter branches: fls. pure shining canary-yellow, produced freely. M.D.G. 1912:253.

AA. *Lvs. not thread-like: fls. pea-shaped.*

B. *Fls. yellow.*

corniculàtus, Linn. Bird's-foot Trefoil. Babies' Slippers. Perennial, prostrate or ascending, a few in. to 2 ft. high, glabrous or hairy: lfts. obovate or ovate, ½in. long, the 2 stipular ones broader and very oblique: fls. yellow, often tinged bright red, 5–10 in an umbel; calyx-lobes about as long as the tube. Temperate regions and Austral.; run wild at certain places in U. S. and Canada. Var. **flòre-plèno** has showy double fls.—A hardy trailer for covering dry banks and rockwork, blooming all summer and autumn. Also grown for forage.

BB. *Fls. pink or white.*

austràlis, Andr. Perennial, diffuse, sometimes subshrubby, glabrous or pubescent: lfts. narrower than in *L. corniculatus,* and the stipular ones less dissimilar, but varying from obovate and under ½in. long, to linear and 1–1½ in. long: fls. usually pink, but varying from white to purple-red. Austral. B.M. 1365. L.B.C. 11:1063 and B. 5:211 (as *L. albidus*).

BBB. *Fls. normally dark purple or dark red.*

C. *Lfts. linear-lanceolate.*

Jacobæus, Linn. Perennial, subshrubby: lfts. few, narrow and long-acuminate: fls. about 3 in a flat-topped cluster, dark purple, almost black. Cape Verde. B.M. 79.—Treated as a tender annual bedding plant: blooms for a long season. A yellow-fld. form is mentioned.

CC. *Lfts. obovate to elliptic.*

Tetragonólobus, Linn. (*Tetragonólobus edùlis,* Link. *T. purpùreus,* Moench). Winged Pea. Annual trailer: lfts. 3, broad-ovate: fls. solitary or twin, purplish cardinal-red: pods 4-sided, 2–3 in. long, somewhat fleshy at first; seeds yellowish, nearly globular or somewhat flattened. Medit. region. B.M. 151.—Tetragonolobus was once considered a separate genus, largely because of the 4 leafy wings of the pod. Grown chiefly for food, the pods being eaten when young and the seeds, when roasted, substituted for coffee. Seeds are sown in drills in April. The plants require no special care except water during drought.

Wilhelm Miller.
L. H. B.†

LOÙRYA (Jules Louis Charles Boys de Loury). *Liliàceæ;* by some referred to *Hæmodoràceæ.* An aspidistra-like plant of recent intro.: perennial herb with creeping rhizome: lvs. basal, lengthened and stalked: fls. in dense heads or spikes at the surface of the ground; parts of perianth ovate, becoming spreading; at the throat a corona; anthers 6, sessile. One species: **L. campanulàta,** Baill. Rootstock stout, subterranean: lvs. 1–2 ft. long, oblong-lanceolate, tapering at both ends: fls. basal, larger and more showy than those of Aspidistra and in longer spike, pale yellow (white?) with purple center, broadly campanulate, the 6 lobes broad: fr. blue, 1 in. long. Cochin-China: a very worthy plant. B.M. 7482. G.C. III. 33:107. R.H. 1889, p. 129. It looks like Curculigo, but differs botanically in having basal ovules and in the characters of stamens, the filaments being united in a dark purple membrane which nearly closes the tube, the anthers small and erect.

L. H. B.

LOUSEWORT: *Pedicularis.*

LOVAGE: *Levisticum.*

LOVE-IN-A-MIST: *Nigella.* **Love-lies-bleeding:** *Amarantus caudatus.*

LOWBERRY. A kind of bramble berry lately originated by Stuart Low & Co., Bush Hill Park, Enfield, England. In 1908, the Royal Horticultural Society gave it an award of merit as "a reputed cross between the blackberry and the loganberry, with the color of the former and the size of the latter. The fruits had been ripened under glass." It is hardy in England, making an annual growth of 12 to 18 feet; it is recommended as an ornamental plant for arbors as well as for fruit. Apparently it has not been thoroughly tested in North America.

The fruit is described as very large and long, jet-black when ripe. The flavor resembles that of the blackberry and is sweeter than the loganberry. The berries make excellent jam, with fewer seeds and less cores than that made from blackberries. The cultural treatment should be that given the loganberry.

LOWIÀRA. A generic name for a garden hybrid (Stuart Low & Co., England) between *Sophronitis grandiflora* and *Brassolælia* "Helen." The name follows the form of Linneara and Adamara (which see). The hybrid is *Lowiàra insígnis*, Rolfe. "The fls. show much of the Sophronitis character, but the sepals are not widely spreading; the sepals and petals are 2½ in. long, the latter nearly 1¼ in. broad, and the color dark rosy salmon; the lip is 2 in. long and entire, with an undulate crenulate margin, and the color rose-purple with a yellowish white throat; the column is broad, whitish and over ½in. long." O.R. Dec., 1912.

LOXOSCÀPHE (Greek, *an oblique boat*). *Polypodiàceæ.* A small group of low southern hemisphere ferns of doubtful relationship; by some botanists referred to Asplenium, by others to Davallia. Indusium forming a compressed, suborbicular or cup-shaped sac, open only at the top: lvs. with linear segms. For cult., consult *Davallia.*

thecíferum, Moore (*Davállia concínna,* Schrad.). Lf.-stalks 3–4 in. long; lf.-blades 6–9 in. long, bipinnate; segms. 2–3 lines long, ½ line wide. S. Amer. and Afr.

fœniculàceum, Moore (*Davállia fœniculàcea,* Hook.). Lf.-stalks 6–8 in. long; lf.-blades 9–18 in. long, quadripinnate; segms. less than ½ line wide. Fiji Isls.

L. M. Underwood.
R. C. Benedict.†

LUCÙLIA (probably adapted from a native name). *Rubiàceæ.* Glasshouse plants grown for the flowers.

Two species of tender shrubs from the Himalaya and Khasia Mts., bearing in winter terminal corymbs sometimes a foot across, composed of 20–40 pink or white, fragrant, salver-shaped fls. with 5 rounded lobes, each fl. being 1½–2 in. across. A plant of *L. gratissima* is on record which attained 6½ ft., bearing 24 bunches of fls. each 2 ft. in circumference, beside 30 smaller bunches. Calyx-tube top-shaped; lobes unequal, deciduous; stamens 5, inserted on the tube of the corolla; filaments very short; disk annular; ovary 2-celled; style 2-branched: caps. almost woody, 2-valved, many-seeded.

For house decoration, *L. gratissima* is one of the most beautiful winter-flowering shrubs, and deserves to become more popular with florists for Christmas sales. The wood ripened after flowering furnishes the best cuttings. Newly rooted plants require a night temperature of 60° at first, but the temperature should be gradually reduced and the plants hardened off before they are planted outdoors for the summer. Young plants should never be allowed to get dry from the time of first potting until they are taken outdoors. For potting, a light soil is desirable. When the pots are well filled with roots, apply liquid manure two or three times a week until the buds appear. During the summer the plants should be syringed daily, as they are subject to red-spider. The plants should be lifted, potted and brought indoors the last week of August. If left out later they do not set flower-buds so well. As soon as the buds appear the plants should be moved to a warmer house, with a night temperature of 55°. After flowering, the plants should be trimmed somewhat, given less water, kept in a night temperature of 45° and syringed daily. They start slowly, but make hardy growths for planting out. (George McWilliam.)

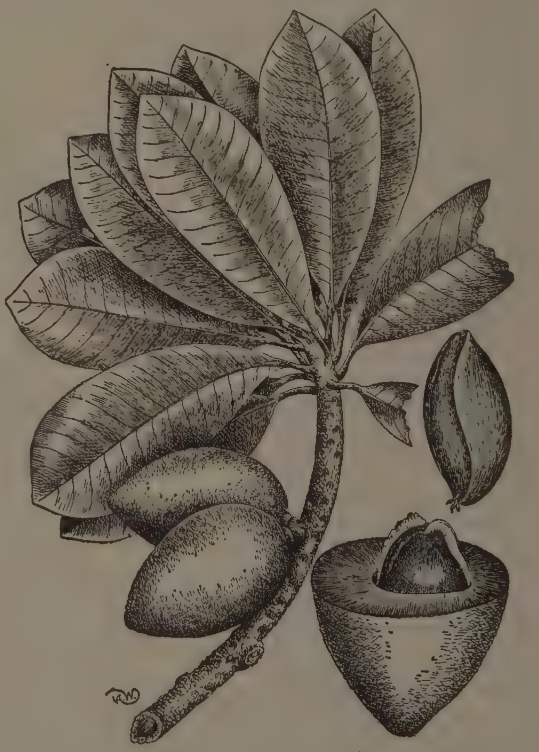
gratíssima, Sweet. In the wild a tree or spreading shrub 10–16 ft.: lvs. opposite, ovate-oblong, acuminate, acute at the base, 4–6 in. long: panicle decussately branched; fls. pink or rose, forming a gorgeous rounded mass; corolla-lobes 1½ in. across, imbricated in the bud; stamens inserted in the tube, slightly exserted. Temperate Himalaya, 4,000–6,000 ft. altitude. B.M. 3946. G.C. III. 21:81; 43:12. R.H. 1843:385; 1890:180. Gn. 35, p. 58; 41, p. 469; 55, pp. 42, 107; 59, p. 49; 78, p. 623. J.H. III. 48:457; 54:459. G. 1:581; 29:671 H.F. 4:120. H.U. 4, p. 353. A.F. 7:443; 10:679.—*L. speciòsa,* Hort., is apparently a form of this species with large and deep-colored fls., and strong growth.

L. Pinceàna, Hook. Bush, 4–6 ft.: lvs. smaller than in above, elliptic-lanceolate and acuminate: fls. in a compound cyme, the lobes pure white above, changing to a cream, with a rosy tinge, outside rosy and the tube red. Distinguished by the presence of 5 pairs of tubercles at the base of each sinus. Khasia Mts., etc., 3,000–5,000 ft. B. M. 4132. Gn. 35, p. 59, and 41, p. 469.

Wilhelm Miller.

LUCÙMA (Peruvian name of one species). *Sapotàceæ.* A group of tropical trees and shrubs, several of which are cultivated, principally in America, for their edible fruits. Other well-known trees which belong to the same family are the sapodilla (*Achras Sapota*) and the star-apple (*Chrysophyllum Cainito*), both of which resemble the lucumas in having fruits with soft, melting flesh of very sweet flavor.

The genus is characterized by lvs. more or less elongate, usually broadened upward; by the imbricate calyx, with lobes in 1 or 2 series; and by the tubular corolla, with stamens opposite the lobes, alternating



2213. The mamey sapote.—Lucuma mammosa. (Spray × ⅙) with the staminodes. The fr. is a berry, 2–10-celled, the seeds exalbuminous.—Species perhaps 60, mostly in Amer. but extending to New Guinea and Austral.

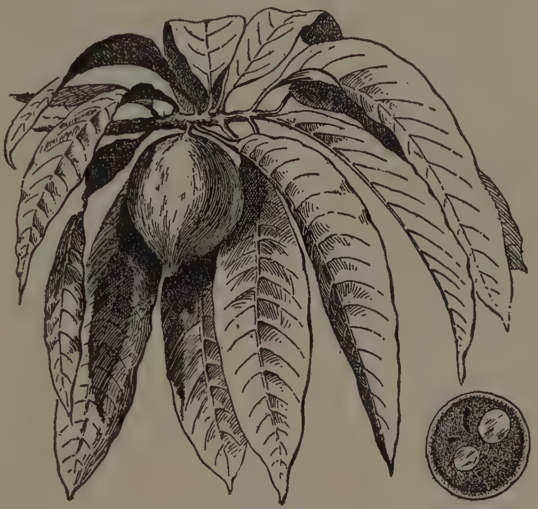
mammòsa, Gaertn. Marmalade Fruit. Mamey Sapote. Mamey Colorado. Sapote. Fig. 2213. A large erect tree, 30 to nearly 100 feet high, cult. in Mex., Cent. Amer., the W. Indies, and N. S. Amer. Lvs. obovate to oblanceolate, cuneate at base, rounded to acute at apex, 4–10 in. long, 1½–4 in. broad, glabrous, light green above, paler or brownish beneath: fls. pedicellate or subsessile, in glomerules of 2–5; calyx-lobes 8–10; corolla white, 5-lobed, ciliate; stamens 5, inserted slightly lower than the staminodes, anthers elliptic-ovate; style conical-elongate, obtuse at tip; ovary 5-celled: fr. globose to elliptical, 3–7 in. long, rusty brown, usually 1-seeded by abortion. Considered a native of Cent. Amer. Pittier has referred this species to *Calocarpum mammosum*, Pierre, while Cook makes it *Achradelpha mammosa.*

nervòsa, A. DC. (*L. Rivicòa* var. *angustifòlia*, Miq.). Ti-es. Egg-Fruit. Canistel. Fig. 2214. A small tree, 10–25 ft. high, with spreading branches: lvs. oblong-obovate to oblanceolate, 4–8 in. long, glabrous, bright green, acute: calyx-lobes 5, the inner ones rounded at the apex; corolla whitish, lobes ovate; style columnar, stigma slightly dilated; ovary 5-celled: fr. globose to ovoid, orange-yellow, 2–4 in. long, usually 2- or 3-seeded. A native of N. S. Amer., but cult. in other parts of Trop. Amer., naturalized on some of the Florida keys.

Caimìto, Roem. (*Poutèria Caimìto*, Radlk.). Abiu. A small tree, about the size of *L. nervosa*, and very similar in appearance: lvs. obovate to lanceolate, 4–8 in. long, acute, bright green, glabrous: fr. ovate-elliptical, bright yellow, 2–4 in. long, usually 2- or 3-seeded. A native of Peru, but cult. in other parts of S. Amer., especially on the coast of Brazil.

In addition to the above may be mentioned the jacana, or hakana, of Porto Rico (*L. multiflòra*, DC.), with oblong or globose frs. 1½–2 in. diam., and sweet, mealy, yellow, edible pulp resembling in appearance the yolk of an egg, inclosing 1–3 seeds. Another noteworthy species is *L. obováta*, HBK., the "lucuma" of Peru and N. Chile, with fr. about the size and shape of a small orange, containing yellow pulp of excellent quality surrounding 1 to several seeds and inclosed in a thin, bright, dark green skin. According to W. E. Safford, specimens of this fr., usually divided into halves, and of the glossy subglobose seeds, are frequently found in prehistoric graves of the coast tribes of Peru, and facsimiles of the fr. in the form of terra-cotta vases are also dug up with Peruvian mummies. *L. Pálmeri*, Fern., is listed in S. Calif.: shrub, to 10 ft., with reddish brown bark on young branches: lvs. dark green, oblanceolate or narrow-obovate: fls. in 2's or 3's or solitary, the corolla twice as long as calyx; stamens and staminodia inserted at top of corolla-tube: fr. over 1 in. long, yellow. Mex. *L. salicifòlia*, HBK., has proved hardy at Santa Barbara: lvs. 5–7 in. long and 1 in. wide, lanceolate, somewhat acuminate, entire and shining: fls. yellowish green, in 2's or 3's, axillary; ovary hirsute, ovate; style about equaling the corolla. Mex. *L. Sellòwii*, A. DC. Lvs. linear or linear-lanceolate, acute, entire or somewhat repand, shining, the young ones tomentose: fls. on solitary or twin axillary pedicels, the corolla tubular, the calyx-lobes and corolla-lobes 4: drupe oblong, size of a pigeon's egg, beaked. Brazil. R.H. 1900, pp. 33, 34.

The most important member of the genus is without doubt *L. mammosa*, the mamey sapote, a common fruit in Cuba, and not infrequently seen on the Central American mainland. It can be grown in extreme south Florida, though it does not seem to thrive on shallow calcareous soils. California has so far proved too cool for it, and no trees of any size are known in the state. It is said to prefer a deep, rich soil and a rainfall of about 70 inches per annum. The fruit is commonly elliptical, and about 6 inches in length. Within the thick woody skin, somewhat rough and rusty brown on the surface, is the soft melting flesh, of a beautiful reddish salmon color, and of about the same consistency as a ripe canteloupe. The large elliptical seed can be lifted out of the fruit as easily as that of an avocado; it is hard, brown and shining, except on the ventral surface, which is whitish and somewhat rough. To one unaccustomed to tropical fruits, the flavor of the mamey sapote is at first somewhat cloying because of its utter lack of acidity; when made into a sherbet, however, as is done in Havana, it is delicious and sure to be relished at first trial. Although natives of tropical countries commonly eat the fruit while fresh, it is also made into marmalade, or used as a "filler" in making guava cheese. The Cubans prepare from it a thick jam, known as *crêma de mamey colorado*, which is delicious. The fruits are picked when mature, and laid away in a cool place to ripen, which takes about a week. If shipped as soon as picked from the tree they can be sent to northern markets without difficulty, and are occasionally exported from Cuba and Mexico to the United States. The season of ripening is during the summer; in Costa Rica the tree is said to lose its foliage in the dry season, flowering at the same time. The seed contains a large oily kernel, which has a strong smell and a bitter taste. According to Pittier, it is used in Costa Rica, after being finely ground, to prepare an exquisite confection; the same authority states that it is sometimes used by the Indians, after being boiled, roasted and ground, to mix with cacao, imparting a bitter taste to the beverage. The foliage of the mamey sapote resembles that of the loquat (*Eriobotrya japonica*), except in its lighter color and entire margins. Propagation is by seed, young trees coming into bearing at the age of five to seven years. Before planting it is well to remove the hard outer husk from the seed; it is then easily germinated by planting in light, sandy loam, barely covering it with soil.



2214. The Ti-es.—Lucuma nervosa. (×¼)

The ti-es (*L. nervosa*) is esteemed in Cuba, where it is called canistel, and is also popular among many of the residents of southern Florida. It is too tender to be grown in California, unless in the most sheltered locations. Unlike the mamey sapote, the tree succeeds on thin poor soils, and seems to be at home on the Florida keys. Its season, in Florida, is from December to March. The fruits when ripe are broadly oval to round, orange-yellow in color, commonly about 3 inches in length, and produced upon short stems toward the ends of the branches. The flesh is dry and sometimes mealy in texture, bright orange-yellow, often likened to the yolk of a hard-boiled egg, which it greatly resembles in appearance but not in taste. The flavor is sweet and rather cloying, to the novice at least, while the aroma is peculiar and somewhat musky. The seeds are one to three in number, oval, about an inch in length, hard, dark brown and shining, except on the ventral surface, which is dull, pale brown. The fruits usually require several days to soften after being picked from the tree, and as the skin is soft and delicate they do not ship so well as those of the mamey sapote. This species is not put to many different uses, the fruit usually being eaten while fresh. The tree is ornamental in appearance, with bright green, glossy foliage, and rarely grows to a height of more than 20 feet. It is usually propagated by seeds, young plants requiring three to five years to come into bearing. The hard outer husk should be removed from the seed before planting.

The abíu of tropical Brazil (*L. Caimito*), greatly resembles the ti-es in growth and foliage, but is easily distinguished by its light yellow fruit, with translucent, whitish, rather juicy flesh, of less cloying flavor than that of the ti-es. The abíu is very popular among the Brazilians, and is commonly cultivated at Rio de Janeiro, Bahia, and other points along the coast. The fruits vary from 2 to 4 inches in length, are usually ovate in form, and have a thick, closely adhering skin, within which lies the soft and melting flesh and two or three large oval seeds. It must be fully ripe to be appreciated; if cut while still firm, a milky latex exudes which is sticky and objectionable in the mouth, while the fruit has a strong taste of tannin. The same is true of other species. The tree, called *abiero* in Portuguese, thrives on a rich clay loam, with an abundance of moisture, and is propagated by seed.

Little has been done to improve any of the lucumas. There is much variation among seedlings, not only in size and quality of fruit, but in productiveness and other characters as well. The best ones should be selected and propagated by some vegetative means, such as budding.

F. W. Popenoe.

LUDDEMÁNIA: *Lueddemannia.*

LUDWÍGIA (C. G. Ludwig, botanist and botanical author at Leipzig, 1709–1773). Sometimes spelled *Ludvigia. Onagràceæ.* Herbs, listed among aquatics.

Annual or perennial aquatic or semi-aquatic small herbs: fls. small and inconspicuous in the axils of the lvs., the parts usually in 4's: fr. a terete ribbed or winged caps.: lvs. mostly small and entire or very nearly so, usually not distinctly petioled, alternate or opposite, the opposite-lvd. species by some referred to Isnardia.—Species about 25, widely spread in warm and temperate regions. The sts. are often creeping, sometimes floating. The ludwigias have little standing as horticultural subjects. They are sometimes useful in bog-gardens, and one is advertised for aquaria. Three names are in the American trade.

A. *Lvs. alternate.*

alternifòlia, Linn. Seed-box, or Rattle-box. An erect shrub, 2–3 ft. or more tall, in appearance not unlike an epilobium, the root sometimes tuberous: lvs. lanceolate or oblong-lanceolate, narrowed below, entire or sometimes with mere suggestions of teeth: fls. large for the genus (½in. across), with yellow caducous petals: caps. large, square in cross-section. Bogs and wet woods in eastern half of U. S.—Interesting, but not showy.

AA. *Lvs. opposite.*

palústris, Ell. (*Isnárdia palústris*, Linn.). Water Purslane. Trailing in muddy places or floating on shallow water, rooting at the joints: lvs. oval or oval-oblong, narrowed into a short petiole: fls. very small, usually reddish.—Nova Scotia to Calif. and Mex.; Eu., Asia; offered as a bog-plant.

Mùlerttii, Mulertt. Lvs. oval to lance-oblong, narrowed into short petioles, entire: fls. yellow: fr. oblong, truncate on top, ⅜in. long.—Intro. from S. Amer. by Hugo Mulertt, then of Cincinnati, and described in "Isis" (published in Germany) in 1880 or 1881, and also in the "Aquarium," Vol. III, pp. 43, 64. It is now widely distributed amongst growers of aquarium plants. It seems not to have been studied by systematic botanists. It is prized for its graceful habit and because it is evergreen. Grows well from cuttings and from seeds. Mulertt, now residing in Germany, gives the following additional information: From the soil coming with rhizomes of nymphea from the Amazon Valley in 1878 this ludwigia made its appearance. At first the plants were not considered to be unusual, but it soon became a favorite with customers, and it has now been widely distributed among aquarists. In Germany, where it is now frequently prop. from seed, several varieties have appeared, but although they retain the evergreen character they do not develop the graceful shape and brilliant crimson coloring of the foliage of the type. "The plant wants a shady location with a high temperature in a water-depth of about 15–18 in. to display its full character below the water-surface. In a sunny location, during summer, it grows above water, the foliage then displaying glossy dark brownish green on top and crimson-purple (or violet-crimson) below. Yellow flowers soon appear in the axils of the lvs. and develop into little caps. that bear the seeds. If left in the caps., these retain life for 6 or 8 years."

L. H. B.

LUEDDEMÁNNIA (Herr Lueddemann). *Orchidàceæ.* A small group of S. American orchids, allied to Cycnoches, but resembling Acineta in habit and requiring treatment similar to the acinetas: sepals oblong and acute, arched; petals cuneate-oblong and acute; ovary pubescent or velvety; fls. handsome, very many on a pendulous peduncle.

L. Lèhmannii, Reichb. f. (Cycnoches Lehmannii, Reichb. f.). Lvs. long and petioled, acute: pseudobulbs furrowed, pyriform, 6 or 7 in. long: fls. 20–30, wax-like, orange-yellow; sepals copper-colored on exterior. Colombia.—*L. Pescatòrei*, Reichb. f. (Cycnoches Pescatorei, Lindl. & Paxt.). Lvs. lanceolate, glaucous, leathery: fls. 30–50, about 1¾ in. diam., sepals orange-brown; petals and lip deep yellow, the disk hairy: peduncle 3 ft. Colombia. B.M. 7123.—*L. Sanderiàna*, Kränzl.=Lacæna bicolor.—*L. tríloba*, Rolfe. Pseudobulbs and lvs. smaller than in two preceding, the lvs. about 1 ft. long and the ovoid pseudobulb about 2½ in. long: fls. deep orange-yellow, the peduncle short (about 6 in.); lip marked with chocolate-red; sepals with a crimson flush. Andes.—*L. Vyvereàna*, Schlecht. Allied to L. Pescatorei, but lip with a longer claw and different shape, with a smaller basal callus, and a less prominent thickening in middle of the blade. Peru.

L. H. B.

LUÈHEA (F. Karl van der Lühe, Austrian botanist interested in the Cape of Good Hope). *Tiliàceæ.* About 16 species of trees and tall shrubs from the warmer parts of Amer., with usually toothed lvs. and handsome white or rosy fls. borne in a terminal panicle, or sometimes in the axils: sepals and petals 5; stamens numerous, the outer ones often without anthers; ovary 5-celled: caps. rather woody, loculicidally semi-5-valved. A species was intro. into Santa Barbara, some years ago, from Paraguay. It is probably *L. divaricàta*, Mart., with lvs. oblong or elliptic to oblong-lanceolate, irregularly serrate, grayish beneath. Luehea is also spelled Luhea, and the genus of this name of the Verbenaceæ is a S. African group referred to Stilbe.

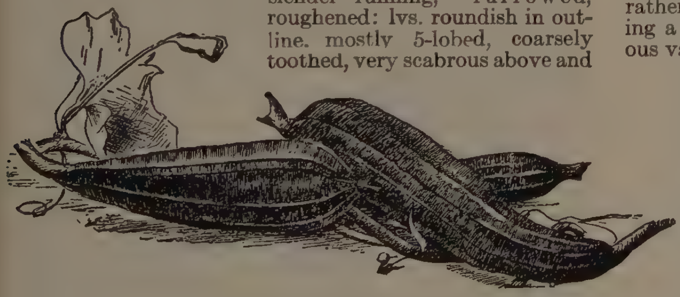
LUÈTKEA (after Fr. Luetke, Russian sea captain, in charge of the fourth Russian voyage around the world). Syn. *Eriogýnia. Rosàceæ.* A prostrate and trailing undershrub, forming dense carpets, with ascending flowering shoots 2–6 in. high, small alternate trifid lvs. and small white fls. in upright racemes. It is closely related to Spiræa, but differs in its habit, the 3-cleft lvs., in the carpels being dehiscent on both sutures and in the stamens being connate at the base. It is best adapted for rockeries and to be treated like other alpine plants; it is rarely seen in cult. Prop. is by greenwood cuttings and division. The only species is **L. pectinàta,** Kuntze (*Spiræa pectinàta,* Torr. & Gray. *Eriogýnia pectinàta,* Hook.). Lvs. 3-cleft, with linear lobes trifid at the apex, bright green, with the petiole ½–¾in. long: racemes 1–2 in. long; fls. white, ⅓in. across. Alaska to Calif., in the high mountains. Bot. Gaz. 15:241, pl. 14. Hooker, Fl. Bor. Am. 88.

Alfred Rehder.

LÚFFA (*luff* is the Arabic name). *Cucurbitàceæ.* Rag Gourd. Dish-cloth Gourd. Vegetable Sponge. About 8 species of annual tendril-climbing herbs, inhabiting the tropics of the Old and New Worlds, mostly in the former. Lvs. 5–7-lobed: tendrils simple or multifid: fls. monœcious or diœcious, the staminate ones in a long-stalked raceme or cluster, the pistillate solitary and shorter-peduncled; calyx bell-shape or top-shape, strongly 5-lobed; corolla of 5 soft yellow or whitish petals, sometimes ragged-edged; stamens usually 3, borne in the calyx-tube: fr. a long, gourd-like, 3-celled pepo, becoming dry when ripe and the fibrous interior sponge-like. In the South it has been called "California okra."

The luffas have come into more or less prominence in American gardens, being an importation from the tropics, and China and Japan. In other countries, the fruit is eaten when young, being cooked like squash or served in soups and stews. The young fruit is sometimes sliced and dried. (See Georgeson, A. G., Sept., 1892, and Bailey, Bull. 67, Cornell Exp. Sta.) In this country, luffas are grown mostly for curiosity and ornament. The fibrous interior of the dried fruit, when bleached and prepared, is used as a sponge for the bath and for scrubbing (whence "vegetable sponge"). The culture is the same as for cucumbers and melons. They are tender plants, running 10 to 15 feet. The luffas are widely dispersed in the tropics as cultivated plants. The genus divides itself into two groups,—those species (*L. cylindrica* and *L. acutangula*) with fruits not spiny or tuberculate, and those with spiny fruits.

cylíndrica, Roem. (*Momórdica cylíndrica,* Linn. *L. ægyptìaca,* Mill. *L. Petòla,* Ser. *L. Veìtchii,* Naudin. *L. fœtida,* Hort. [at least in part], not Cav. *L. Fabiàna, L. japónica, L. mexicàna* [?] and *L. noctiflòra álba,* Hort.). Naga itouri of Japanese. Sua-kwa of Chinese. The commonest dishcloth gourd: sts. slender-running, furrowed, roughened: lvs. roundish in outline, mostly 5-lobed, coarsely toothed, very scabrous above and beneath: staminate fls. 2–3 in. across, wilting in the sun; ovary cylindrical or clavate, pubescent, destitute of distinct ridges, ripening into a slender cylindrical curved fr. 1–2 ft. long; seeds black or rarely whitish, narrow-winged. A var. *macrocárpa* is listed. Probably native to the Old World, but widely distributed in the tropics. A.G. 13:526.



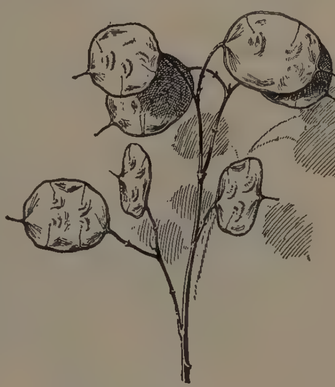
2215. Luffa acutangula. (×⅑)

acutángula, Roxbg. (*L. fœtida,* Cav.). Sing-kwa of Chinese. Fig. 2215. Lvs. rounded, scarcely lobed, very coarsely toothed: ovary 10-ribbed, ripening into a strongly ribbed fr.; seeds black and wingless. Tropics, probably indigenous in Asia. B.M. 1638. Gt. 48, p. 136.

L. H. B.

LUÍSIA (after Don Luis de Torres, Spanish botanist). *Orchidàceæ.* Curious epiphytic orchids, grown indoors.

Stems with simple or branched erect sts. bearing alternate, elongated, fleshy-terete lvs.: fls. sessile, on short lateral spikes; sepals and petals sub-similar, connivent or half-spreading; labellum adnate to the column, somewhat concave, with small lateral lobes and a large, spreading, entire or bifid middle lobe; column short; pollinia 2, on a broad, short pedicel.—About 20 species in Trop. Asia, the Malay Archipelago, and Japan. These plants are rarely cult. They grow well in any warm or intermediate house, requiring the treatment given to aërides. A few of the species are listed by orchid specialists, but are not in the general popular trade.



2216. Lunaria annua. (×¼)

L. Amesiàna, Rolfe. Habit of Vanda teres: fls. rather large, in clusters at sides of st.; sepals and petals pale yellow, brown outside; lip white, shaded yellow and spotted purple. India. G.C. III. 14:32.—*L. burmánica,* Lindl.=L. teretifolia.—*L. platyglóssa,* Reichb. f.=L. teretifolia.—*L. Psỳche,* Reichb. f. Sts. erect: lvs. about 6 in. long, quill-like: fls. axillary, in 2's; sepals and petals green; lip marked with deep purple. Burma. B.M. 5558.—*L. teretifòlia,* Blume (L. burmanica, Lindl. L. platyglossa, Reichb. f. L. zeylanica, Lindl.). Stout, often producing very many downy roots: fls. small, chocolate-brown, in few-fld. clusters; petals and sepals sometimes whitish; lip convex, oblong. Burma. B.M. 3648 (as Cymbidium triste).

L. H. B.†

LUNÀRIA (*luna,* Latin for moon; name referring to the silvery white partition of the large pods). *Cruciferæ.* Satin Flower. Moonwort. Honesty. Herbaceous perennials and annuals, natives of Europe and western Asia, of two species, both of which are cultivated in old gardens.

Leaves rather large, simple, broad or more or less cordate: fls. purple, in terminal racemes or panicles, rather large and showy: fr. stalked in the calyx, becoming a very large flat disk-shaped silicle, with deciduous valves and a thin persistent septum; seeds winged, 2–4 in each compartment.—The plants are of easy cult. under any ordinary garden conditions. They are interesting for their showy fls., but are grown mostly for their great flat pods, which are used in winter bouquets. They are called "honesty" because the seeds can be seen through the pods. Prop. by seeds; or the second species rarely by division. The species sometimes escape from gardens for the seed readily self-sows.

ánnua, Linn. (*L. biénnis,* Moench). Fig. 2216. Loose-hairy plant, 1½–2½ ft. tall, branching as it matures: lvs. somewhat cordate or halberd-cordate, coarsely and irregularly toothed, stalked: fls. numerous, pink-purple, fragrant, in May and June: pods about 2 in. long and somewhat narrower, very flat, rounded at the ends, tipped with the persistent style, interesting. Eu. R.H. 1857, p. 30.—Frequent in old-fashioned gardens; especially useful in sandy damp places, even in shady spots. There is a recent form with handsomely variegated lvs. Var. **corcyrénsis,** Hort., has blue fls. Corfu. There is a white variety which is much admired, since the fls. do not possess the bright color of the type species which is objectionable to many persons.

redivìva, Linn. Differs from the last in being perennial, the fls. usually larger and lighter colored (often grayish purple), May and June, and the pod elliptic or lance-elliptic, and tapering to either end: 1½–7½ ft. tall. Eu.—Less common and less valuable than *L. annua*. Thrives best in partial shade.

L. H. B.
A. C. Hottes.†

LUPÌNUS (from the Latin *lupus*, a wolf, because a crop of lupines was supposed to destroy fertility). *Leguminòsæ*. Lupine. Usually herbs adapted to borders in masses, and to all places in which low-growing showy herbs would be found; some make good bedding-plants, others cut-flowers.

Mostly annuals or herbaceous perennials, 2 species in cult. being shrubby: lvs. usually digitate, with 5–15 entire lfts.: fls. with calyx deeply bilabiate, 5-toothed, unequal; corolla with simple erect broadly ovate standard, having strongly reflexed sides; wings united at the apex and inclosing the keel; stamens united into a closed tube: pod 2-valved, flattened, inclosing several large seeds.—A group of about 300 species mostly confined to W. N. Amer., a few growing in E. N. Amer., Peru, Brazil, Mex., Guatemala, Afr., and in the Medit. region. A very variable genus in the garden. There are numerous garden hybrids of unknown parentage. Some of these names will be found in the supplementary list. Voss groups these under the name of *L. hybridus*, Hort., and its vars. *atrococcineus* and *roseus*, or florists' lupines. They have variegated fls.

In addition to those described below the following native species have been advertised, mostly by Gillett, in 1881, for western collections. Probably they are not in cultivation. They are mostly described in Bot. Calif.: *L. albicaulis*, *L. Chamissonis*, *L. lepidus*, *L. leucophyllus*, *L. ornatus* and *L. villosus*.

The lupines are showy plants with conspicuous flowers in terminal racemes, those of the species in cultivation being mostly verticillate. The flowers are blue, white or yellow, or a union of these, papilionaceous and free-blooming. All are of easy cultivation in any garden soil, except that they are said not to succeed in soil containing lime. They are propagated by seed, the perennials also by division. They do not bear transplanting when once established, hence it is recommended to sow seed where the plants are finally desired. A few species are of value economically for soiling or plowing under.

1. **arbòreus,** Sims. Tree Lupine. Lfts. 7–11, lanceolate-linear, acute, silvery downy below, entire: fls. somewhat verticillate, in tall, loose racemes, sulfur-yellow, fragrant: pods pubescent, 1½–3 in. long. July–Sept. Common in Calif. B.M. 682. Gn. 30, p. 289; 47:398. —Shrub, 4–10 ft. high, somewhat pubescent, not hardy at the north. Var. Snow Queen or Queen of the Snow is pure white. Var. **lùteus** has been advertised.

2. **densiflòrus,** Benth. (*L. Menzièsii*, Agardh). A dwarf shrub, 18 in. tall with long hairy lf.-stalks and handsome compound lvs.: fls. in a long dense raceme, deep yellow, large. Calif. B.M. 5019.—A very attractive plant.

2217. Lupinus parviflorus.

3. **diffùsus,** Nutt. Deer Cabbage. St. decumbent and many-branched, 1–2 ft., somewhat woody at the base, densely silky: lvs. large, oval or oblong-ovate, obtuse, mucronate, on long, soft-silky petioles: fls. more or less alternate, on a very long (6–12 in.) spike, light blue, the standard with a greenish yellow center: pods oblong, flattish, very woolly. April. Sandy barrens, N. C. to Fla.—Hardiness N. not determined.

4. **perénnis,** Linn. Sun-Dial. Common Wild Lupine. St. erect, 1–2 ft. high, rather stout, minutely pubescent: lvs. long-petioled, soft-downy; lfts. 7–9, obovate-oblong to lanceolate, obtuse, glabrous above, soft-downy below: fls. in large, loose terminal spikes or racemes, alternate, blue, varying to white. June, July. Canada to Fla. B.M. 202. Mn. 6:101. B.B. 2:269.—

Desirable species, growing in the poorest soil, preferring sandy land. Grows from subterranean rootstocks.

5. **parviflòrus,** Nutt. Fig. 2217. Fls. light blue, smaller than in *L. perennis:* lfts. 5–11, broad-linear to oblanceolate. N. Mex. to Wash.

6. **argénteus,** Pursh. Fls. blue or cream-colored: lfts. 5–8, linear-lanceolate. W. N. Amer. B.B. 2:269. Var. **ròseus,** Hort. Fls. rosy-pink, lower half slightly paler. Suitable for herbaceous border.

7. **rivulàris,** Douglas (*L. cytisoìdes,* Agardh). Perennial, 4–6 ft. high: sts. stout: lvs. large and handsome; lfts. 7–9, oblanceolate: fls. deep pink or rose-purple, in long racemes. W. N. Amer.

8. **polyphýllus,** Lindl. (*L. grandiflòrus,* Lindl.). Stout, erect species, forming tufts 2–5 ft. high: lvs. distant, mostly radical, long-petioled; lfts. lanceolate, glabrate above, silky hairy below, 2–6 in. long: fls. on long stalks, alternate, pedicelled, deep blue: pod 1–1½ in. long, narrow. June–Sept. Wash. to Calif. Gn. 45, p. 459; 55, p. 215.—A common garden species of merit, succeeding in any good soil. Var. **Mòerheimii,** Hort. A very beautiful new intro. from the firm of B. Ruys at Dedemsvaart in 1906–7. Two to 3 ft. tall, much more compact and erect than the true polyphyllus forms: fls. long-lived, bright pink, rose to white. Without doubt it is the best variety which exists. R.B. 37:225; 38:217. G.M. 51:613. Var. **albiflòrus,** Hort. (var. *álbus*), is white, bold and showy. Var. **bícolor,** Hort., is variegated blue and white. Var. **Fóxei** is uncertain.

9. **nootkaténsis,** Donn. St. hairy, decumbent, with long, spreading hairs, 2–3 ft. high: lfts. 5–9, narrowly obovate-oblong, smooth above, hairy below, mucronate; stipules lanceolate, nearly as long as the lfts.: fls. in dense racemes, blue, variegated with red and yellow, with large veins, variable. May–July. Nootka Sound. B.M. 1311; 2136.—Coarse stocky species, said to be unsuitable for small gardens, but of merit.

10. **platténsis,** Wats. One to 1½ ft. high: lfts. 7–10, oblanceolate, spatulate or narrowly oval: raceme loosely fld., terminal; corolla blue, standard with a conspicuous dark spot. June, July. Neb., Wyo., Dak. B.B. (ed. 2) 2:348.

11. **sulphùreus,** Douglas. St. very erect, white silky: lfts. narrowly lanceolate, densely hairy on both sides, shorter than the petiole: fls. in tall, dense racemes, sulfur-yellow: pods woolly, 1 in. long. July, Aug. Mountains of Ore. R.H. 1890:252.—Strong species branching above, bare below.

12. **lùteus,** Linn. Yellow Lupine. Fig. 2218. St. erect, nearly simple, hairy, 2 ft. high: lfts. lanceolate, acute, hairy: fls. on pubescent stalks longer than the lvs., verticillate, yellow, fragrant: pod oblong, flat. June, July. S. Eu. B.M. 140.—Succeeds in the poorest soil. Useful for cut-fls., for the border, for fodder or for plowing under to improve sandy soils. As a fodder, it may be fed green or as hay.

13. **pilòsus,** Linn. St. hairy, 2–4 ft. high: lfts. oblong-lanceolate, hairy: fls. verticillate, pedicelled, rose, the middle of the standard red. S. Eu.

14. **micránthus,** Douglas. St. slender, 3–12 in. high, hairy: lfts. linear, ¼–1 in. long: fls. in short, dense racemes, somewhat verticillate, very small, violet, standard and wings narrow: pod linear. Gravelly places, Ore. to Calif.—A slender plant of branching habit.

15. **affínis,** Agardh. St. rather stout, 8–10 in., pubescence very short: lfts. broadly wedge-obovate, obtuse, long, more or less smooth above; stipules one-half the length of lvs.; petioles twice longer than the lfts.: fls. on a long stalk, deep blue: pod linear. Early spring. Calif.—A free, hardy species, often growing very rank.

16. **hirsùtus,** Linn. Blue Lupine. St. hairy, 2–3 ft. high, branching toward the top: lfts. 7–9, oblong or oblong-oval, hairy, long-petioled: fls. somewhat verticillate or scattered, large, mostly purple, sometimes variegated with blue or violet: pod large, very hairy. July, Aug. S. Eu.—Used ornamentally and as an economic plant for the same purposes as *L. luteus.* It is valuable for fodder and for plowing under. Var. **álbus,** Hort., has white fls. Var. **rùber,** Hort., and var. **fòliis ròseis** are advertised.

2218. Lupinus luteus.

17. **hirsutíssimus,** Benth. Annual, 1½–2½ ft. high: sts. rather stout, covered with stiff hairs: lfts. 5–7, cuneate-obovate: fls. large, deep reddish purple, very showy. Calif.

18. **álbus,** Linn. White Lupine. Erect st., 1½ ft. high: lfts. obovate-oblong, 5–7, hairy below, 1½–2 in. long: fls. alternate stalked, on erect sts., quite large, white: pods large. Summer. Asia and S. Eu.—A good fodder plant said to be of greater thrift than *L. luteus,* and remaining green longer. Succeeds well on the poorest soil and is valuable for plowing under. Seeds are sown April–July, and the plants are plowed under when in flower.

19. **pusíllus,** Pursh. Lfts. about 7, mainly oblong, acute: fls. blue or purple. Prairies. B.B. 2:270.

20. **Hártwegii,** Lindl. St. erect, 2–3 ft. high, somewhat branching: lfts. 7–9, oblong, obtuse, very hairy: fls. in many-fld. elongated racemes, blue; standard whitish, then reddish. June–Sept. Mex. B.R. 25:31. Var. **álbus** is also sold. Possibly a perennial but cult. as an annual.

21. **mutábilis,** Sweet. St. erect, branched, somewhat woody, 5 ft. tall: lfts. 7–9, lanceolate, obtuse, hairy below and somewhat glaucous: fls. large, somewhat verticillate, fragrant; standard white mixed with blue, becoming blue with a large yellow mark in the center; wings and keel white. June–Aug. Mountains of S. Amer. B.M. 2682.—Attractive species, erect and branching but half-hardy.

Var. **Crúckshanksii,** Hook. (*L. Crúckshanksii,* Gray). Fls. large, fragrant, white, the standard yellow-rose, becoming violet. B.M. 3056.

22. **subcarnòsus,** Hook. St. 3–10 in. high, ascending, silky pubescent: lfts. 5–7, obovate-lanceolate, obtuse, somewhat fleshy, smooth above, silky below and on margins: fls. in pyramidal racemes, alternate; standard orbicular, deep blue with a white spot in the center divided by a longitudinal fold: pod linear-oblong, silky. Spring. Texas. B.M. 3467.—Spreading species of merit.

23. **nànus,** Douglas. St. slender, ½–1 ft., often branching from the base, hairy: lfts. 5–7, linear to oblanceolate, pointed, pubescent both sides, stalks 1–3 times longer: fls. in elongated, loose racemes, verticillate on slender stalks, large, white, pointed with clear blue, edged with deeper blue; wings bluish, hiding white-

brownish keel: pod hairy. June, July. Calif. B.R. 1705.—This species and its varieties are very floriferous, giving a fine effect in masses and in the border. Var. **álbus** Hort., white tinged with lilac. Var. **álbo-coccíneus,** Hort. A very compact variety, the lower half of the spike rosy red, the upper white; forms compact tufts and is called a superior variety.

L. angustifòlius, Linn., with blue fls., is much grown in Eu. as a fodder plant and for plowing under: annual. Native to the Medit. region.—*L. pubéscens*, Benth. Perennial or subshrubby, the pubescence short, spreading, hardly silky in the new parts: lfts. 7–9, oblong-lanceolate, acute, shorter than the petiole, pubescent on both sides: fls. loosely arranged almost in whorls: pedicels shorter than the calyx: pod hirsute, 4–6-seeded. The above is from the original description. Bentham neglects to state the color of the fls., but an allied species has blue fls. Mottet must be in error in calling this an annual. Mex., Cent. Amer., Colombia.—*L. villòsus*, Willd., is mentioned occasionally in garden literature.

The following are garden hybrids of unknown origin. They mostly have variegated fls. and are common in cult.: *L. atroviolàceus*. Perennial, 2 ft. high: fls. dark violet, striped with white and yellow.—*L. cœléstinus*. Annual, 2 ft. high: fls. light blue.—*L. Dúnnettii*. Fls. lilac-purple, gold and white. According to Voss, this is the same as the kinds known to the trade as L. superbus, L. insignis (Vilmorin, not Dippe), L. tricolor elegans and L. superbus Dunnettii. There is also a double form.—*L. hýbridus*. Probably mixed kinds.—*L. trícolor*. See L. Dunnettii.

A. Phelps Wyman.
John W. Harshberger.†

LÙZULA (Latin *lux*, light, in diminutive derivation, from some fanciful attribute or interest). *Juncàceæ*. Wood Rush. About forty species of grass-like or rush-like, often cespitose, perennial herbs of wide distribution in temperate and frigid regions, some of them adapted to borders and for colonizing. Several species are native in the United States and Canada, but none of them seems to be listed in the trade; two European species are offered abroad. By some, the name Juncoides is used in place of Luzula.

These are plants of mostly inconspicuous green or scarious fls. (sometimes white) in umbel-like, paniculate, corymbose or congested infl., the fls. always bracteolate; perianth parts distinct, glumaceous; stamens usually 6; ovary 1-celled: fr. a dry 3-seeded caps.: lvs. soft, usually hairy or webby: dry ground. Juncus, to which the genus is closely related, differs in its mostly 3-celled and many-seeded caps.

sylvática, Gaud. (*L. máxima*, DC. *L. sylvéstris*, Hort. *Juncoìdes sylváticum*, Kuntze). Rhizome woody: st. 12–18 in. or more high: lvs. linear-lanceolate, hairy-edged, shining, striate: panicle double-compound, much exceeding the lf.-like bracts; perianth-segms. bristle-pointed; filaments very short. Eu.—There is a form with variegated (striped?) foliage.

nívea, DC. (*Juncoìdes níveum*, Kuntze). Fls. pure white, large, in thick panicles that are shorter than the lf.-bracts; filaments about equaling the anthers: plant 12–18 in.: lvs. linear, hairy on margin. Eu., Alps.—Useful in dry bouquets.

L. H. B.

LYCÁSTE (fanciful name). *Orchidàceæ*. Epiphytic and terrestrial orchids; very popular as greenhouse subjects.

Pseudobulbs ovate or oblong-ovate, bearing 1 to several plicate lvs. at the summit, and sheathing lvs. from the base: sepals subsimilar, spreading, the lateral pair united with the base of the column and forming a spur-like chin or mentum; petals smaller, projecting forward, with the tips often recurved; labellum 3-lobed, the lateral lobes erect, middle lobe ascending or recurved, with a fleshy, tongue-like callus on the disk; pollinia 4.—About 30 species, all natives of S. Amer., Mex., and the W. Indies. The fls. are freely produced and remain in good condition on the plant for several weeks. They are normally borne singly on erect or sub-erect bracted scapes, but sometimes twin-fld. stalks occur. In Lycaste the scape arises from the very young leafy axis, which does not develop until several months later. The scape, therefore, appears from the base of the bulb. Among the species, *L. Skinneri* is a favorite orchid with growers. The species of Lycaste are very distinct from each other and do not fall readily into natural groups. The arrangement in the key is purely artificial, and does not indicate close relationship among the species grouped together.

The genus Lycaste is closely allied to Maxillaria and has a similar geographical range, being found from Mexico and the West Indies to Peru and southeastern Brazil. Notwithstanding this wide distribution, however, they readily subject themselves to one general mode of treatment, and may be grown in a bright cool portion of the cattleya or warm end of the odontoglossum department, where they should receive plenty of indirect solar light, moisture and sufficient ventilation to ensure an active atmosphere. During winter, the night temperature should range from 50° to 55° Fahr. and that of the day from 60° to 65°, or a few degrees higher, with sun heat and ventilation. In summer, the air should be as cool as possible, and contain plenty of moisture. When lycastes are growing they need a good supply of water at the roots, and should never be allowed to remain dry for a long time, even when at rest. Light syringing overhead is beneficial at all times in bright weather when air can be admitted. The deciduous species, however, must be carefully watered when at rest, for it must be remembered that in casting their foliage they lose most of their active radiating surface, thus reducing evaporation to a minimum.—For special treatment, they may be divided into three groups, *L. aromatica*, *L. costata* and *L. tetragona* forming good types. The *L. aromatica* section embraces, besides the type, *L. candida*, *L. cruenta*, *L. Deppei*, *L. lasioglossa*, *L. macrobulbon* and kindred sorts, all more or less deciduous. These grow best in pots in a mixture of equal parts chopped peat fiber and sphagnum moss, with a small quantity of leaf-mold added. About one-third of the pot space should be devoted to drainage of broken charcoal or potsherds, and the compost must be carefully and rather firmly pressed in about the roots, leaving the base of the pseudobulbs on a level with or a little below the rim of the pot. The best time for transplanting is just after the plants start into new growth, at which time give a more abundant supply of water.—The *L. costata* group includes, besides the type, such species as *L. lanipes*, *L. locusta* and *L. Skinneri*, which, excepting the last, are but semi-deciduous, large-growing species. They succeed best under pot culture, and should be grown in a compost of about equal parts chopped sod, from which some of the fine soil has been removed, and decomposed leaves, adding a little chopped live sphagnum to keep the soil porous and to retain moisture. The compost should become nearly dry occasionally to prevent it from becoming sour.—The *L. tetragona* section is small; all are sempervirent and grow best under basket culture in porous material consisting of chopped peat fiber and live sphagnum, well mixed and interspersed with nodules of charcoal. The compost should be pressed in moderately firm about the roots to keep the plant steady, and newly imported pieces should be held in place by copper or brass wire crossed between the pseudobulbs.—Lycaste stock is usually supplied by new importations, but plants may be increased by cutting through the rhizome between the pseudobulbs, two at least being left to each piece. (Robert M. Grey.)

KEY TO THE SPECIES.

A. *Middle lobe of lip semi-oblong or rounded, usually obtuse or truncate.*
B. *Lip pilose with long hairs* .... 1. **lasioglossa**
BB. *Lip glabrous or short-pubescent.*
C. *Fls. white, sometimes green-tinged (some white forms of L. Skinneri might be sought here).*
D. *Sepals ivory-white; disk-plate grooved and emarginate* ...... 2. **costata**
DD. *Sepals greenish white; disk-plate with 3–5 parallel raised lines* .... 3 **lanipes**
CC. *Fls. not entirely white.*
D. *Petal white.*
E. *Sepals oblong, but little longer than petals.*
F. *Front lobe of lip entire; sepals pale green* .... 4. **candida**
FF. *Front lobe of lip denticulate; sepals olive* .... 5. **plana**
EE. *Sepals lanceolate, much longer than petals* .... 6. **Schilleriana**
DD. *Petals not white.*
E. *The lip toothed or fringed.*
F. *Sepals and petals olive, much longer than the maroon orange-bordered lip* .... 7. **gigantea**
FF. *Sepals and petals dull green, about as long as the green white-bordered lip* ...... 8. **locusta**
EE. *The lip entire.*
F. *Size of fls. 3 in. across or less; sepals yellowish green.*
G. *Sepals and petals streaked with red-brown; lip white* ..... 9. **tetragona**
GG. *Sepals and petals not marked; lip yellow.*
H. *Base of lip blood-red; front lobe quadrate*. 10. **cruenta**
HH. *Base of lip yellow; front lobe oblong-ovate* .... 11. **macrobulbon**
FF. *Size of fls. 5–6 in. across; sepals rose (white in some forms)* .... 12 **Skinneri**
AA. *Middle lobe of lip spatulate* .... 13. **aromatica**
AAA. *Middle lobe of lip ovate-acuminate*.... 14. **Deppei**

1. **lasioglóssa**, Reichb. f. Pseudobulbs 3 in. long, ovoid, compressed: lvs. 8–12 in. long, elliptic-lanceolate: scape 1-fld.; fls. 5 in. across; sepals spreading, narrowly oblong, dull brown or greenish brown; petals one-third as long, erect, concave, obtuse, golden yellow; labellum as long as the petals, also golden yellow; lateral lobes short, obtuse; middle lobe oblong, covered with long, soft hairs; callus ovate, notched. Autumn and winter. Guatemala. B.M. 6251. G.M. 44:179.—Very odd but not showy.

2. **costàta**, Pseudobulbs oblong, compressed, 3–5 in. long: lvs. 2–3 at the apex, 6–10 in. long, broadly oblong-lanceolate, acuminate: scape erect, as long as the pseudobulb; fls. large, nearly white or creamy yellow; dorsal sepals oblong-lanceolate, the lateral sepal similar but falcate, united with the column to form a blunt spur; petals smaller, somewhat undulate; lateral lobes of the labellum small, erect; middle lobe ovate-rotund, toothed. Peru. B.M. 5706 (as *L. Barringtoniæ* var. *grandiflora*). J.H. III. 42:5. C.O. 10.

3. **lánipes**, Lindl. Pseudobulbs large: lvs. lanceolate, 12–18 in. long: fls. solitary, as many as 15 on a plant, creamy white; sepals and petals oblong-lanceolate; labellum smooth; lateral lobes ovate-obtuse; middle lobe oblong, obtuse, serrate, with a concave, ribbed callus. Oct. Ecuador.—Lindley says the fls. are pale green, 2½ in. long before they expand, without a trace of any other color.

4. **cándida**, Lindl. (*L. brevispatha*, Klotzsch). Pseudobulbs ovoid, much compressed: lvs. oblong-acuminate: fls. about 2 in. across; sepals spreading, reflexed and acute at the apices, oblong, slightly woolly at base, yellowish green, sometimes dotted with light rose; petals whitish, revolute, obtuse; labellum white, with a few rose-colored spots; disk-plate obtuse, emarginate at the apex; column hairy on the inner surface. Costa Rica. C.O. 6. Var. **Lawrenceàna**, Hort. Sepals and petals tinted with rose, otherwise the fls. are like those of the type. Var. **rùbra** has been offered.

5. **plàna**, Lindl. A robust plant, with large ribbed pseudobulbs and ample-pointed oval lvs.: fls. 3–4 in. across; sepals oblong, plane, rich madder-red inside; petals smaller, with recurved tips, white, tipped with crimson; labellum smaller, white spotted with crimson; side lobes crenulate; middle lobe rounded, obtuse, serrate, crested. Winter. Bolivia. B.R. 29:35. Var. **Measuresiàna**, Williams. Sepals reddish brown, tipped with green; petals and labellum white spotted with bright rose, except on the margins of the petals. Autumn.

6. **Schilleriàna**, Reichb. f. Plant resembling *L. Skinneri* in habit: pseudobulbs 2-lvd.: lvs. elongate-lanceolate, up to 2 ft. long: scape 1-fld., suberect, 8 in. long; sepals large, spreading, oblong-lanceolate, 4 in. long, brown; petals erect, with recurved tips, small, 1½ in. long, white, speckled with brown on the back; labellum as long as the petals, white, speckled and tinged with rose; side lobes small; middle lobe ovate-quadrate, crenulate; callus tongue-shaped, concave. Often the parts of the fl. are more or less spotted and hairy in places. July, Aug. Colombia. Gt. 39:1321. Var. **magnífica,** Hort. Sepals long, olive-tinted; petals and lip white.

7. **gigantèa**, Lindl. Pseudobulbs often 6 in. high, bearing 2–3 oblong-lanceolate lvs. 1½–2 ft. long: scape 1-fld., somewhat shorter than the lvs.; sepals ovate to lanceolate, 3 in. long, rather olive-green; petals somewhat smaller, lanceolate, spreading, of the same color; labellum oblong-lanceolate; side lobes acute; middle lobe ovate, acuminate, serrate, rich maroon bordered with a narrow orange margin; crest fleshy, emarginate. The fl.-sts. are said to attain a height of 2 ft., with a single large fl. In most of the specimens in cult. the lip is abruptly rounded off. June–Aug.; Nov., Dec. Widely dispersed in Cent. Amer. B.M. 5616. B.R. 31:34. C.O. 7.

8. **locústa**, Reichb. f. Pseudobulbs pyriform: lvs. oblong-ligulate, acute: fls. smaller than those of *L. Deppei*, all green except the white column; the odd sepal oblong, obtuse; the lateral ones linear-oblong, acute; petals bent down inside of the lateral sepal; labellum with acute side lobes and a semi-oblong, fleshy, convex middle lobe, all green; on the disk are 2 narrow keels, confluent behind into a fleshy emarginate callus. Peru. B.M. 8020. G.C. III. 49:260.

9. **tetragòna**, Lindl. Pseudobulbs ovate, tetragonal: lvs. solitary, ovate-lanceolate: scape 1–4 fld.; fls. greenish streaked with crimson; sepals and petals oblong-ovate, rather obtuse, half-spreading, the 2 lower forming a blunt, projecting angle at base; labellum smaller, white and purple or green and purple, with a shovel-shaped appendage on the disk. Fls. not beautiful, but very fragrant, remaining fresh for two months. June. Brazil. B.M. 3146 and B.R. 1428 (both as *Maxillaria tetragona*).

10. **cruénta**, Lindl. Pseudobulbs compressed: lvs. many, oblong, membranaceous: scape bearing 1 yellow fl. (rarely 2), much larger than those of *L. aromatica;* sepals ovate, obtuse; petals similar, erect and smaller; labellum half as long as the sepals; lateral lobes rounded; middle lobe rounded-truncate, crisp on the margin, pubescent; crest small, fleshy. Like *L. aromatica*, but the lvs. much broader, fls. larger, and the labellum of different shape and somewhat spotted with purple.

March, April. Guatemala. B.R. 28:13 (as *Maxillaria cruenta*). Gn. 44:394 (as *L. aromatica*). C.O. 9.

11. **macrobúlbon,** Lindl. Pseudobulbs very large, ovate, compressed, with several large, oblong, acute lvs.: scapes usually 2 from each pseudobulb, much shorter than the lvs.: fls. large, yellow; sepals ovate-oblong, spreading; petals shorter, somewhat concave, with recurved tips; labellum oblong, as long as the petals, spotted on the disk with brown. Colombia. B.M. 4228 (as *Maxillaria macrobulbon*).

12. **Skínneri,** Lindl. Pseudobulbs oblong-ovate, 3–5 in. high, 1–2-lvd.: lvs. oblong-lanceolate, 9–12 in. long: scapes 5–6 in. long, each bearing a single waxy fl. 5–6 in. diam.; sepals ovate-oblong, white tinged with rose; petals half as long, broadly ovate, pointing forward with acute, reflexed tips, striated and tinged with dark rose; lateral lobes of the labellum erect truncate; middle lobe oblong-ovate, recurved with a fleshy tongue-shaped callus on the disk, dark crimson-purple. Guatemala. B.M. 4445. P.M. 11:1. Gn. 25:410; 30, p. 374; 37:397. F. 1861:65 (var.). A.F. 4:519. J.H. III. 34:367; 60:321. A.G. 14:433. C.L.A. 6:166. G.M. 53:894. C.O. I. O.R. 19:276.—The most useful of the genus. Spring. The following varieties are advertised:

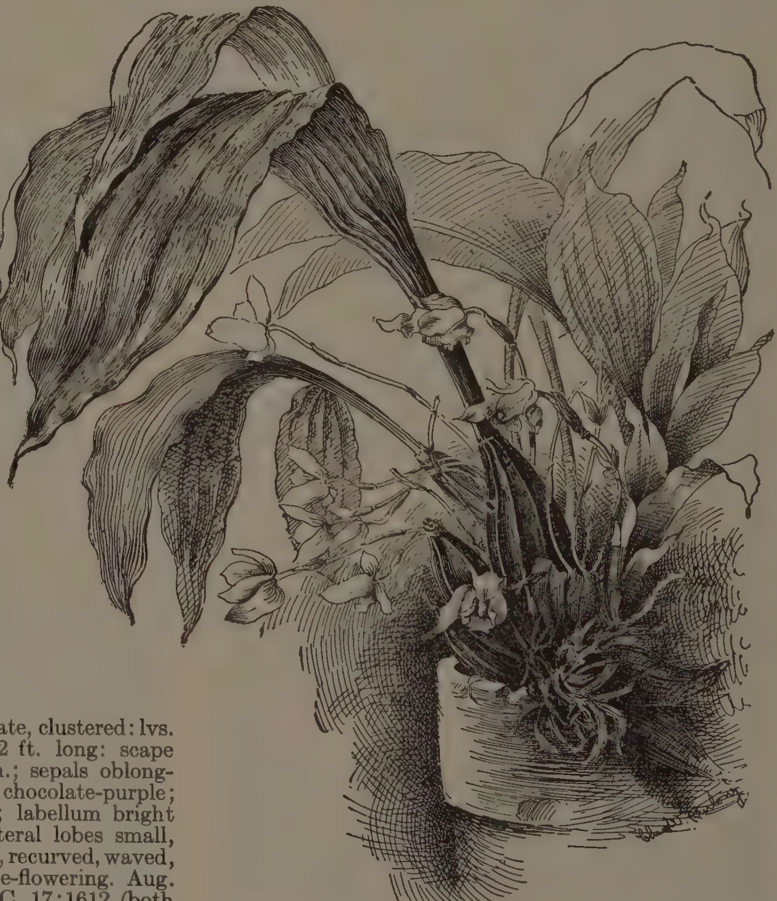
Var. **álba,** Hort. A large-fld. white variety with a tinge of yellow at the base of the labellum and a yellow, tongue-shaped appendage in its throat. I.H. 27:405. Gn. 25:410. F.M. 1872:35. G.C. III. 7:424. A.F. 6:631. J.H. III. 50:253; 62:541. C.O. 1*a*. O.R. 19:177. Var. **álbo-sanguínea.** No description. Var. **armeníaca,** Hort. Sepals white; petals and lips suffused with apricot-yellow. G.M. 53:72. J.H. III. 60:51. C.O. 1*d*. Var. **cándida,** Hort. White. Var. **delicatíssima,** Hort. Fls. large, rose-white; labellum white, blotched with rose. Feb. C.O. 1*b*. Var. **Denholmiàna,** Hort. Upper lobes of fl. rich crimson; lip almost white. Var. **grandiflòra.** No description. Var. **hellemènse,** Cogn. Fls. bright rose-purple. C.O. 1*e*. R.B. 35:53. Var. **purpuràta,** Hort. Sepals and petals rose-white; labellum crimson-purple. Var. **ròsea,** Hort. A beautiful variety with deep rose fls. and a white labellum spotted with crimson. Var. **supérba.** Sepals and petals white; labellum crimson.

13. **aromática,** Lindl. Fig. 2219. Pseudobulbs ovate, compressed: lvs. many, sheathing, oblong-lanceolate: scape erect, 1-fld., shorter than the lvs.; fls. yellow, 2½ in. across; sepals and petals ovate-oblong, acute; the latter smaller and pointing forward; lateral lobes of the labellum with narrow, projecting blades; middle lobe spatulate, dentate, recurved, and having a large truncate plate as a crest. Winter and spring. Mex. B.R. 1871.—Floriferous.

14. **Déppei,** Lindl. Pseudobulbs ovate, clustered: lvs. 3–4, broadly elliptic-lanceolate, 1½–2 ft. long: scape erect, bearing 1 or 2 fls. 4 in. diam.; sepals oblong-lanceolate, dingy green, spotted with chocolate-purple; petals smaller and cucullate, white; labellum bright yellow, with a few purple spots; lateral lobes small, rounded; middle lobe ovate-acuminate, recurved, waved, with a yellow callus. Vigorous and free-flowering. Aug. to May and June. B.M. 3395. L.B.C. 17:1612 (both as *Maxillaria Deppii*). P.M. 2:268 (as *Maxillaria Deppei*). C.O. 11.—Named after Deppe, but originally spelled Deppii. Var. **punctatíssima,** Hort. Fls. much spotted with dark purple. Guatemala.

L. Bàlliæ=L. Skinneri × L. plana var. Measuresiana. Sepals terra-cotta with a rosy flush; petals rose, fading, to white at tips; lip white, irregularly carmine-spotted. O.R. 11:80. G.M. 46:356; 55:219.—*L. Bárringtoniæ*, Lindl. Fls. green to tawny yellow; sepals and petals ovate-lanceolate; lip 3-lobed, the front lobe ovate; fimbriate. W. Indies.—*L. Cáppei*=L. Skinneri × L. plana.—*L. Chárlesworthii*=(?).—*L. Dyeriàna*, Sander. Fls. pale green; lip obscurely 3-lobed, the front lobe elliptic, denticulate, reflexed, obtuse. Peru. B.M. 8103.—*L. eisgrubénsis*=L. Skinneri × L. lasioglossa.—*L. formòsa*=(?). Fls. large, cream-white, with red spots at the base of the petals.—*L. fulvéscens*, Hook. Sepals and petals lanceolate, acuminate, red-brown, paler at base; lip orange-brown, oblong, obtuse. Colombia. B.M. 4193.—*L. Gròganii*=L. aromatica × L. Deppei.—*L. Henniseàna*, Kränzl. Allied to L. lasioglossa. Fls. large; petals nearly white; lip quite glabrous, white or cream-colored; column pure white, hairy above the middle. Colombia.—*L. hýbrida*=L. Skinneri × L. Deppei. Fls. in size between the two parents, cream-color, minutely dark-spotted.—*L. Imschootiàna*, Lind. & Cogn.=L. Skinneri × Maxillaria nigrescens. Sepals pale yellow, red-spotted; petals pale yellow, smaller, less spotted; lip yellow, dark purple at base. Lind. 410. J.H. III. 62:425.—*L. làta*, Rolfe. Allied to L. Barringtoniæ. Fls. white, except sepals and apex of petals which are green. Peru.—*L. Lucianiàna*=L. Skinneri × L. lasioglossa.—*L. macrophýlla*, Lindl.=L. plana.—*L. Micheliàna*, Cogn. In general aspect much resembling L. aromatica, but with the floral segms. broader. Mex.—*L. peruviàna*, Rolfe. Sepals and petals light brown, becoming paler at base, lip nearly white. Peru.—*L. Pourbaixiàna*=L. Skinneri var. superba × L. Deppei.—*L. Rógersonii*=L. Skinneri × L. plana.—*L. trícolor*, Reichb. f., var. *álbens*. Sepals pale green; petals white with greenish tinge at ends. —*L. Túnstillii*=(?). Sepals rose-colored; petals white with rose-pink spots; lip ruby-red, with white markings. G.C. III. 54:415.—*L. xytrióphora*, Reichb. Sepals light greenish brown, with a horny point on the under side; petals yellowish green at base, white above; lip small, white, sometimes stained rose-pink. Peru (?).

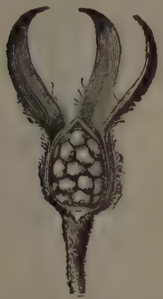
HEINRICH HASSELBRING.
GEORGE V. NASH.



2219. Lycaste aromatica.

LÝCHNIS (from the Greek word for *lamp*, in allusion to the flame-colored fls. of some species). Including *Agrostémma* and *Viscària*. *Caryophyllàceæ.* Interesting flower-garden herbs.

The technical generic characters are so variable as to allow the genus to be thrown into Silene or to be broken up into 7 or 8 distinct genera (for the latter, see Williams, Journ. Bot. 31:167; Journ. Linn. Soc. 32:11), according to the point of view of the particular author. They are mostly erect-growing, and the lvs. are opposite and entire. The caps. usually has but one locule or compartment, and the seeds are borne on a central or axile placenta (Fig. 2220). The styles are usually 5 or rarely 4, in this differing from Silene (in which the styles are 3), and the calyx-teeth are commonly 5. In some species, the styles are 3 and the caps. is more than 1-loculed at base, but in these cases the habit of the plant and minor technical characters enable one to refer them to Lychnis rather than to Silene. The stamens are 10; and the petals 5 and usually with a 2-cleft scale or a pair of teeth at the base of the blade.—As defined above, the genus contains 40–50 species, annuals, biennials, and perennials, of the temperate parts of the northern hemisphere. Agrostemma and Viscaria might be separated, although the distinctions are not very marked. Agrostemma has the 5 stamens opposite the petals and the petals are not appendaged; Lychnis would then be distinguished as having the stamens alternate with the petals, and the latter are often or usually appendaged so as to form a crown in the corolla. If Lychnis is restricted to those species in which the caps. is 1-celled to the base, then Viscaria may be distinguished for certain species that are several-celled at the base (see *Viscaria*). For horticultural purposes these distinctions are not important. Petrocoptis is here kept distinct. In the following synopsis of the garden kinds, little attempt is made to follow technical botanical divisions.



2220. Capsule and seeds of Lychnis Githago. (×¾)

2221. Flower of Lychnis Githago.

Some of the species of Lychnis are amongst the best known of old-fashioned flowers, as the mullein pink, Maltese cross and ragged robin. These are essentially flower-garden subjects, and of simple cultural requirements. Others, as *L. alpina*, are better known as border or rockwork plants (see also *Petrocoptis*). All species are easily grown from seeds, the biennials and perennials blooming the second year. The perennials are often propagated by division. All of them apparently thrive in the sun.

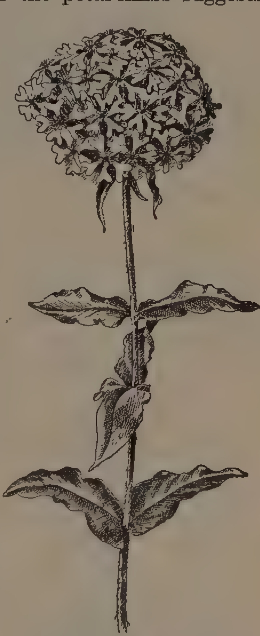
A. *Calyx-lobes long and leafy; petals not crowned.*

1. **Githàgo,** Scop. (*Agrostémma Githàgo,* Linn.). CORN-COCKLE. Figs. 2220, 2221; also 1515. An annual weed in wheat-fields, and difficult to eradicate because the seeds are not readily screened from the wheat in the thresher or fanning-mill: plant strict, 2–3 ft. tall, white-hairy: lvs. nearly linear: fls. long-peduncled, red-purple and showy, the obovate entire petal-limbs exceeded by the narrow calyx-lobes—these lobes falling when the fr. is ripe. Eu.—Rarely cult. in old gardens.

AA. *Calyx-lobes not prolonged and leafy; petals usually crowned.*

B. *Fls. 1 in. or less across, in dense terminal cymes or umbellate heads. (Forms of No. 14 may be sought here.)*

2. **chalcedónica,** Linn. MALTESE CROSS. JERUSALEM CROSS. SCARLET LIGHTNING. Fig. 2222. Perennial, 2–3 ft. tall, usually loose-hairy, the sts. simple or nearly so: lvs. oblong or cordate-lanceolate, clasping (upper ones often narrow and tapering), short-pointed, hairy: fls. 1 in. long, with narrow upward-enlarging ribbed calyx and spreading obcordate-notched limb. June. B.M. 257. Gn.M. 5:17.—Probably Japanese, but long in cult., and one of the best of all old-fashioned fls. The fls. are usually brick-red to scarlet, but there are varieties with rose-colored, flesh-colored and white blossoms; also with double fls. G. 4:391. The arrangement of the petal-limbs suggests the Maltese cross, hence one of the common names. Rarely persists for a time as a weed.



2222. Lychnis chalcedonica. (×⅛)

3. **fúlgens,** Fisch. (not Hort.). An erect-stemmed perennial, hairy: lvs. ovate to ovate-oblong, roughish, tapering below but scarcely petioled: fls. few, in a rather dense terminal cluster, bright scarlet, each petal divided into 2 broad lobes, on the outer side of which are 2 other and very narrow lobes, the ends of the main lobes slightly toothed; calyx oblong or ovate, 10-ribbed, with erect teeth. Siberia, China, Japan. B.M. 2104. B.R. 478.—Perhaps not in cult. in this country. The plant that passes under this name is probably a form of *L. coronata*. From *L. chalcedonica* it is distinguished by lower stature, much larger fls., and the well-marked side teeth or lobes on the petals.

4. **alpìna,** Linn. (*Viscària alpìna,* Don). Glabrous, tufted, a foot or less tall: lvs. mostly at the base, thickish, linear or oblong: fls. pink, with 2-lobed petals (segms. linear), and short broad calyx with red teeth. N. Asia, Eu., and Amer.; arctic and subarctic. B.M. 394. L.B.C. 9:881 (as *L. suecica*). *L. lappónica,* Hort., is apparently a form of this species; said to be perhaps somewhat dwarfer and deeper in color. G.M. 50:209.—An attractive alpine.

BB. *Fls. mostly larger, borne singly or in loose clusters, or at least the clusters not all terminal.*

C. *Plant white-woolly throughout.*

5. **Coronària,** Desr. (*Agrostémma Coronària,* Linn. *Coronària tomentòsa,* A. Br.). MULLEIN PINK.

Dusty Miller. Rose Campion. Fig. 2223. Biennial or perennial, 1–2½ ft. tall, forking toward the top: lvs. oblong, oblong-oval or oblong-spatulate, the lower ones obtuse or nearly so, tapering to a more or less clasping base: fls. large (1½ in. across), circular in outline, crimson or rose-crimson, borne singly on the ends of the branches; petals with appendages at the throat; calyx with filiform teeth. Eu. and Asia. B.M. 24. J. H. III. 57:571. Gn. W. 26:43. G. 30:401.—A common plant of old gardens, and sometimes escaped. The glowing fls. and white foliage make it a conspicuous plant. A hybrid of this and *L. Flos-Jovis* is figured in G. C. III. 2:101.

2223. Lychnis Coronaria.

6. **Flós-Jòvis,** Desr. (*Agrostémma Flós-Jòvis,* Linn. *Coronària Flós-Jòvis,* A. Br.). Flower of Jove. Fig. 2224. Perennial, 12–18 in., making a clump: lvs. in a rosette, also cauline, oval-lanceolate, more or less clasping: fls. small (½in. or less across), bright red or rose, in a rather dense, umbel-like cluster. Eu. B.M. 398.—Hardy perennial, rarely seen in old gardens.

cc. *Plant not white-woolly, green.*

d. *Petals 2-notched or 2-cleft.* (*Forms of No. 14 may be sought here.*)

e. *Annuals.*

7. **Cœli-ròsa,** Desr. (*Agrostémma Cœli-ròsa,* Linn. *Silène Cœli-ròsa,* Rohrb. *Coronària Cœli-ròsa,* Fries). Rose of Heaven. Fig. 2225. A very floriferous annual, 12–18 in., glabrous: lvs. linear, long-acuminate and very sharp-pointed: fls. on slender sts., about an inch across, the petals only slightly notched, rose-red, with a linear bifid scale at the throat; calyx club-shaped. Medit. region. B.M. 295.—A popular garden annual, loving the sun. There is a white-fld. form; also var. **fimbriàta,** Hort., with toothed petals; and other forms. For an account of the leading garden forms, see Rehder, M.D.G. 1897, p. 346.

2224. Lychnis Flos-Jovis.

Var. **oculàta,** Hort. (*L. oculàta,* Backh. *Viscària oculàta,* Lindl.), is a handsome form with purple-eyed fls. B. R. 29:53. B. M. 4075.

ee. *Biennials and perennials.*

8. **diòica,** Linn. (*L. diúrna,* Sibth.). Red or Morning Campion. Fig. 2226. Coarse, hairy and usually somewhat viscid, 1–2 ft. tall, forking above: lvs. ovate-lanceolate or oblong, the cauline ones broad-based or clasping: fls. normally red (varying to pink and white), in loose, elongating or forking clusters (or at first single on the ends of the branches), opening in the morning, not fragrant, more or less diœcious; calyx oblong, reddish, not exceeding ½in. length: fr. or caps. large and globose, wide-mouthed, the teeth recurved. Eu. and Asia.—Frequent in old gardens, and also run wild in waste grounds in the eastern states. There are double-fld. forms. G.C. III. 48:105 (double).

9. **álba,** Mill. (*L. vespertìna,* Sibth.). White or Evening Campion. Fig. 2227. Very like the last, and perhaps not specifically distinct, but more viscid: lvs. longer: fls. usually white and fragrant and opening at evening; calyx longer and green: caps. ovate to conical, with teeth erect or spreading, not recurved. May, June. Eu.—In old gardens and also escaped. There is a double-fld. form. G. 4:319; 8:511; 30:400. This and the last are easily grown biennials or perennials.

10. **Viscària,** Linn. German Catchfly. Interesting hardy perennial, 6–20 in. high, glabrous but with viscid patches beneath the fl.-clusters: lvs. long-linear, the lower ones tapering toward the base: fls. not large, red, in opposite short-stalked clusters, which form an interrupted glomerate panicle; calyx ¾in. long, reddish, usually somewhat swollen above the middle, with short teeth. Eu., N. Asia. G. C. III. 20:122.—Sometimes seen in old gardens, and a useful plant with a tufted habit; a most profuse bloomer in sunny places. Var. **álba,** Hort. Fls. white. G. M. 56:455. G. 30:401. Var. **spléndens,** Hort., has rose-pink fls. Var. **élegans,** Hort., has scarlet and white-striped fls. There are double-fld. forms. G. 25:347.

11. **Préslii,** Sekera. Perennial (?), 1–1½ ft., with many root-lvs. which are oval-lanceolate or obovate, acuminate: st.-lvs. oval and obtuse, dark green: fls. about 1 in. diam., purple, in forked panicled clusters; petals 2-notched (?); crown fringed, rose; calyx reddish and much inflated. Bolivia.—Apparently little known horticulturally.

2225. Lychnis Cœli-rosa. (Natural size)

12. **yunnanénsis,** Baker. Allied to *L. Flos-cuculi,* but with much the habit of *L. sibirica* (see suppl. list, next page): perennial, many-stemmed, 6 or 7 in. high, the sts. slender and pubescent: lvs. lanceolate or linear-lanceolate, sessile, glaucous-green and pubescent, acute: fls. white, the petals much longer than calyx and usually 2-lobed; filaments longer than calyx, the latter 10-nerved, tubular-campanulate, reddish at margin and the segms. ovate and somewhat glandular. China.—Recently offered.

DD. *Petals 4-lobed or parted.*

13. **Flós-cùculi,** Linn. (*Agrostémma Flós-cùculi,* Don. *Coronària Flós-cùculi,* A. Br.). Ragged Robin. Cuckoo Flower (note the Latin name). Fig. 2228. Perennial, slender, 1–2 ft. tall, slightly roughened, and glandular above: root-lvs. oblanceolate; st.-lvs. lance-linear to linear and rather small: fls. in a loose, cymose-paniculate cluster, red or pink, the petals cut into 4 linear segms.; calyx short-oblong, 10-ribbed. Eu., N. Asia. G. 26:401 (var. *rosea*).—Common in old gardens and also naturalized in parts of the eastern country. The double form (red or white) is prized for its close-packed fimbriate fls. An old-time and deserving favorite, blooming profusely and for most of the season. Hardy.

2226. Lychnis dioica. (×⅕)

Var. **plenissima,** Hort. (*L. plenissima semperflòrens,* Hort.), is an excellent very double form, blooming from spring till autumn, and also forcing well.

DDD. *Petals several-toothed or fimbriate or nearly entire, not simply 2-lobed (perhaps exceptions in some of the forms).*

2227. Lychnis alba. (×⅕)

14. **coronàta,** Thunb. (*L. grandiflòra,* Jacq.). Perennial, or often biennial under cult., erect, glabrous, 1–1½ ft.: lvs. oval-elliptic and acute, the cauline ones sessile or nearly so: fls. very large (2 in. or more across), the wide-spreading petals sharply several-toothed or somewhat laciniate, brick-red, salmon, or cinnabar, scattered or in an open panicle. China, Japan. B.M. 223. L.B.C. 15:1433. G.C. III. 28:205 and 42:189 (the same cut). R.H. 1911:12. G.M. 51:141. F.S. 10:979.—Half-hardy or tender perennial, growing 1–1½ ft. high, mostly a spring and summer bloomer. Of this handsome plant there are various forms, and to at least some of them the name *L. fulgens* is frequently applied.

Var. **speciòsa,** Bailey (*L. speciòsa,* Carr. *L. grandiflòra* var. *speciòsa,* Voss. *L. japónica speciòsa,* Hort.). Usually not so tall, very bushy: lvs. narrower and sharper: fls. very large and redder (usually scarlet), the petals less toothed and indistinctly 2-notched. R.H. 1870–1:530.

Var. **Sièboldii,** Bailey (*L. Sièboldii,* Van Houtte. *L. grandiflòra* var. *Sièboldii,* Voss). Fls. large and pure white, with lacerate and obscurely 2-notched petals.

15. **Miquelìana,** Rohrb. Much like *L. coronata* but well distinguished by petals not eroded, bracts and bractlets short and strict, the infl. spreading, peduncles often about as long as calyx: described as a pretty species forming a spreading bush of olive-green foliage and freely producing salmon-red large fls. in Aug. and Sept. Japan.

16. **Haageàna,** Lem. (*L. fúlgens* forma *Haageàna,* Voss. *L. grandiflòra* var. *Haageàna,* Hort.). Hybrid of *L. fulgens* and *L. coronata* var. *Sieboldii,* and a good intermediate, the fls. being large, with 2-notched petals and 2 short side teeth or lobes and dentate ends to the large lobes. It is a hardy or half-hardy, more or less hairy perennial, 12 in. or less high, in summer producing large clusters of orange-red, scarlet or crimson fls., which are nearly 2 in. across. Very desirable. I.H. 6:195. G.C. III. 42:243. G. 34:675. F.S. 22:2322.

17. **Sénno,** Sieb. & Zucc. Erect-growing villous perennial, with sessile, ovate or lance-ovate lvs. and 1–3 large fls. at the ends of the branches, deep carmine (or in some forms with striped fls.), the petals deeply cut (half their length) into several divisions which are again toothed at the ends; possibly a form of *L. coronata.* Japan.—Little known in this country.

L. Árkwrightii, Hort. Garden hybrid between L. chalcedonica and L. Haageana. Shades of scarlet.—*L. Lagáscæ,* Hook. f.=Petrocoptis.—*L. pyrenàica,* Berger = Petrocoptis. —*L. Sártori,* Hort. Said somewhat to resemble L. dioica but has narrower and more lanceolate lvs. and the inflated calyx is more elongated, the fls. being similar color of purple and ½in. across: about 9–12 in. high. China (?).—*L. sibírica,* Linn. Perennial, from Siberia, apparently not in commerce: cespitose: lvs. linear, somewhat hairy: fls. long-peduncled; calyx campanulate-globose, the lobes very short and obtuse; petals 2-lobed.—*L. striàta,* Hort., offered abroad, "deep scarlet with distinct white stripes," is probably not L. striata, Rydb., of W. U. S.; the latter is a perennial with exserted white or purplish 2-cleft petals and strongly 10-nerved calyx, growing at an altitude of 6,000–10,000 ft. in Colo., Wyo., Utah.

L. H. B.

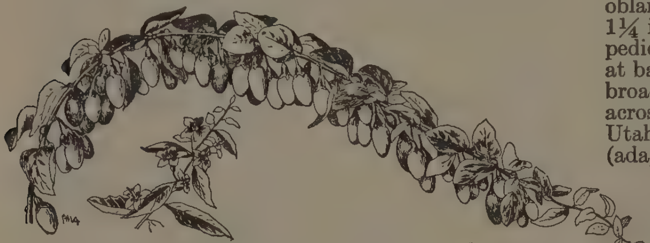
2228. Lychnis Flos-cuculi. (×⅕)

LÝCIUM (Greek, *Lykion,* a name given to a Rhamnus from Lycia, transferred by Linnæus to this genus). *Solanàceae.* Matrimony-Vine. Box-Thorn. Ornamental shrubs grown for their flowers and for the attractive fruits, scarlet in most species.

Deciduous or evergreen, thorny or unarmed: lvs.

alternate, often fascicled, short-petioled, entire, without stipules: fls. axillary, solitary or clustered; calyx campanulate, 3–5-toothed; corolla funnelform, with usually 5-lobed limb; stamens mostly 5: fr. a berry, with few to many seeds.—About 100 species, distributed through the temperate and subtropical regions of both hemispheres.

The matrimony-vines are shrubs with usually spiny branches, rigid in some species, slender and arching or procumbent in others, with rather small and narrow usually grayish green leaves and dull-colored, whitish, purplish or violet flowers, followed by scarlet, rarely yellow or black berries. Most of the species are tender, but *L. halimifolium*, *L. chinense*, and also *L. turcomanicum* and *L. ruthenicum* are hardy North. *L. pallidum* has proved hardy at the Arnold Arboretum. The two first named are especially attractive in fall, when the long and slender branches are loaded with scarlet or bright red fruits, which contrast well with the green foliage. The leaves remain fresh and unchanged in color until they drop, after severe frost. The species are well adapted for covering walls, fences, arbors and other trellis work, but are, perhaps, most beautiful when the branches are pendent from rocks or from the top of walls. They are also used sometimes for hedges, and for warmer regions, especially, *L. horridum* and *L. afrum* may be recommended. The latter is much used in South Africa for this purpose under the name of "caffir thorn." The box-thorns grow in almost any soil that is not too moist. They should not be planted near flower-beds or similar places, where the suckers are apt to become troublesome. Propagation is accomplished readily by hardwood cuttings or suckers; also by layers and seeds.



2229. Lycium chinense. (×⅓)

A. *Lvs. 1 in. long or longer: fls. 5-lobed.*

B. *Corolla-lobes as long or nearly as long as the tube: fls. purplish.*

halimifòlium, Mill. (*L. vulgàre*, Dun. *L. fláccidum*, Koch). Shrub, with long and slender, spiny or unarmed branches, recurving or sarmentose, glabrous: lvs. cuneate, narrow, oblong-lanceolate, acute or obtuse, grayish green, 1½–2 in. long: fls. 1–4, long-pedicelled; corolla ½in. across, limb about as long as tube; filaments hirsute at the base: fr. oval, orange-red or sometimes yellow, to ½in. long. May–Sept. China to S. E. Eu. Gn. 31, p. 334; 34, p. 63. B.B. (ed. 2) 3:168. G.W. 15, p. 346. Var. **lanceolàtum,** Schneid. (*L. lanceolàtum*, Poir.). Lvs. lanceolate: frs. oval. Var. **subglobòsum,** Schneid. (*L. subglobòsum*, Dunal). Dwarfer: lvs. lanceolate: frs. subglobose.—This species and also the following are often confounded with *L. europæum* and *L. barbarum*, which are chiefly distinguished by the filaments being glabrous at the base, by the longer tube and by the narrower and smaller lvs. They are not hardy N. and are rare in cult. while *L. halimifolium* and the following are hardy.

chinénse, Mill. Fig. 2229. Similar to the former, of more vigorous growth: branches to 12 ft. long: lvs. rhombic-ovate to lanceolate, bright green, 1½–3 in.: fls. somewhat larger: fr. scarlet or bright orange-red, ovate to oblong, sometimes almost 1 in. long. June–Sept. China. G.F. 4:102. F.E. 28:641.—The larger-fruited form is sometimes distinguished as var. **ovàtum,** Schneid. (*L. rhombifòlium*, Dipp. *L. ovàtum*, Poir. *L. chinénse* var. *macrocárpum*, Hort.). Lvs. rhombic-ovate, to 4 in. long: fr. very obtuse at the apex, large. Var. **inérme,** Schelle, is a spineless form.

BB. *Corolla-lobes much shorter than the tube: fls. pale greenish white.*

pállidum, Miers. Fig. 2230. Much-branched upright shrub, to 4 ft., with spreading, spiny branches: lvs. oblanceolate, obtuse, glaucous, somewhat fleshy, 1–1¼ in. long: fls. solitary or in pairs, nodding, on short pedicels; corolla pale greenish yellow or whitish, pinkish at base, ¾in. long; tube about 3 times longer than the broadly ovate obtuse lobes: berries globose, ¼–⅓in. across, scarlet. May, June; fr. in July–Aug. Ariz. and Utah to Mex. B.M. 8440. G.C. III. 46:232. G.F. 1:341 (adapted in Fig. 2230). M.D.G. 1908:209.—Very floriferous and attractive from the peculiar color of its fls., which are rather large for the genus; the very ornamental frs. do not seem to be produced regularly in cult. Does not produce suckers and does not grow readily from cuttings.

AA. *Lvs. small, ¾in. long or shorter.*

B. *Foliage glabrous or puberulous.*

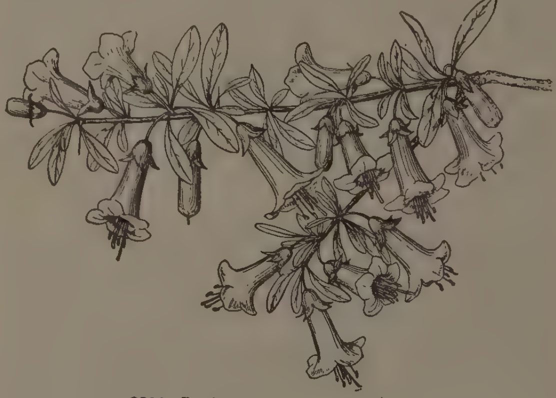
Ríchii, Gray. Shrub, with slender spiny branches: lvs. short-petioled, cuneate, obovate, obtuse, glabrous or minutely puberulous when young, about ½in. long: fls. usually 2–3; calyx as long as pedicels, with elongated teeth; corolla ½in. long, tube longer than 4-lobed limb: fr. globular, bright red, ¼in. across. May–Sept. S. Calif.

hórridum, Thunb. Erect, spiny, much-branched shrub, to 3 ft., glabrous: lvs. sessile, spatulate, glabrous, about ¼in. long: fls. short-pedicelled, small, whitish, with rather slender tube and 3–4-lobed limb. S. Afr.—It is not certain whether the plant in the trade is the true *L. horridum* of Thunberg described above, or *L. afrum*, which is much used in S. Afr. for hedges; the latter is easily distinguished by its large purple fls.

BB. *Foliage glandular-pubescent.*

chilénse, Bert. Shrub, with slender, often procumbent and mostly spineless branches: lvs. cuneate at base, oblong, glandular-pubescent on both sides, grayish green, ⅓–¾in. long: fls. usually solitary; pedicels longer than the 5-lobed, whitish pubescent calyx; corolla about ⅓in. long, pubescent and yellowish outside, limb 5-lobed, purplish within, about as long as tube: fr. orange-red. July–Oct. Chile.—The grayish color and glandular pubescence gives the foliage a frosted appearance. Intro. 1900 by Franceschi, Santa Barbara, Calif.

L. áfrum, Linn. Upright, rigid, spiny: lvs. linear-spatulate, small: fls. solitary, tubular, with short limb, purple, 1 in. long. N. and S. Afr. B.R. 354.—*L. bárbarum*, Linn. Spiny or rarely unarmed shrub, similar to L. halimifolium: fls. 3–6; tube inside and filaments at base glabrous, limb half as long as tube. N. Afr.—*L.*



2230. Lycium pallidum. (×⅔)

califórnicum, Nutt. Spiny shrub, to 2 ft.: lvs. thickish, spatulate, very small: fls. whitish, small: fr. red, small, subglobose. Calif.—*L. europæum*, Linn. (L. mediterraneum, Dun.). Spiny shrub, with spreading branches: lvs. spatulate, thickish: fls. short-pedicelled, with the slender tube much longer than limb. Medit. region.—*L. fuchsioides*, HBK.=Iochroma fuchsioides.—*L. ruthénicum*, Murr. Upright, spiny: lvs. linear, small, thick: fls. small, with rather long tube: fr. globular, black. S. Russia, W. Asia.—*L. turcománicum*, Turcz. Slender, spiny, allied to L. halimifolium: lvs. and fls. smaller, tube more slender and longer: fr. globular. Turkestan, N. China.

Alfred Rehder.

LYCOPÉRSICUM (*wolf peach;* probably an allusion to its inferiority as compared with the peach or possibly to its supposed poisonous qualities). Sometimes written *Lycopersicon. Solanàceæ.* Tomato. Familiar garden fruit or vegetable.

Perhaps nearly a dozen herbs of the western side of S. Amer., two of which are in common cult. for their frs. (which in common speech are classed with vegetables). Fls. small, yellow, nearly rotate when in full bloom, in short superaxillary racemes; stamens 5, connate about the single style; ovary 2-loculed in the non-ameliorated forms, becoming a fleshy many-seeded berry: foliage irregularly or interruptedly pinnate, rank-smelling: plant pubescent, straggling.—Botanically the genus is very close to Solanum, from which it is distinguished by the characteristic pinnately compound lvs., and the longitudinally dehiscing anthers which are prolonged into an empty beak. It is united with Solanum by Wettstein in Engler & Prantl's "Natürlichen Pflanzenfamilien." In native conditions, tomatoes are probably perennial, but in domestication they are treated as if annual. Tender to frost. See *Tomato.*

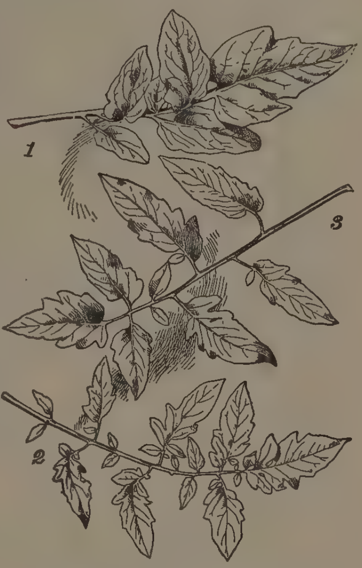
2231. Old-time garden tomato, Lycopersicum esculentum.

esculéntum, Mill. (*Solànum Lycopérsicum,* Linn.). Common Tomato. Figs. 2231, 2235. Plant spreading, with grayish green, mostly conduplicate ("curled") lvs. and slender, ascending shoots: lvs. pinnate, with small, nearly entire lfts. interposed, the main lfts. notched or even lobed toward the base: fls. in a short raceme of 4–6: fr. medium to small, flattened endwise and furrowed on the sides.—In cult. for more than 300 years. Two hundred years ago red and yellow varieties were known. The great evolution of the tomato did not take place until last century, giving rise to the garden race. The plant sometimes escapes from cult. and runs wild for a time.

Var. **vulgàre,** Bailey. Fig. 2232, No. 2. This is the common garden tomato of N. Amer., distinguished by very heavy growth, greener foliage, much larger and plane lvs., the comparative absence of stiffish ascending shoots (in the mature plant), few fls., and larger, "smoother" (i. e., not furrowed) fr., which has numerous locules or cells.—There is every reason for believing that the original tomato had a 2-loculed (2-celled) fr., but the course of amelioration has multiplied the locules; it has also modified the foliage and the stature of the plant.

Var. **cerasifórme,** Hort. (*L. cerasifórme,* Dunal). Cherry Tomato. Still grown for its little globular frs. (in red and yellow), which are often 2-loculed: plant less large and dense-foliaged, the lvs. smaller, grayer: growth more erect.—Probably a very close approach to the wild plant. Frs. used for pickles and conserves.

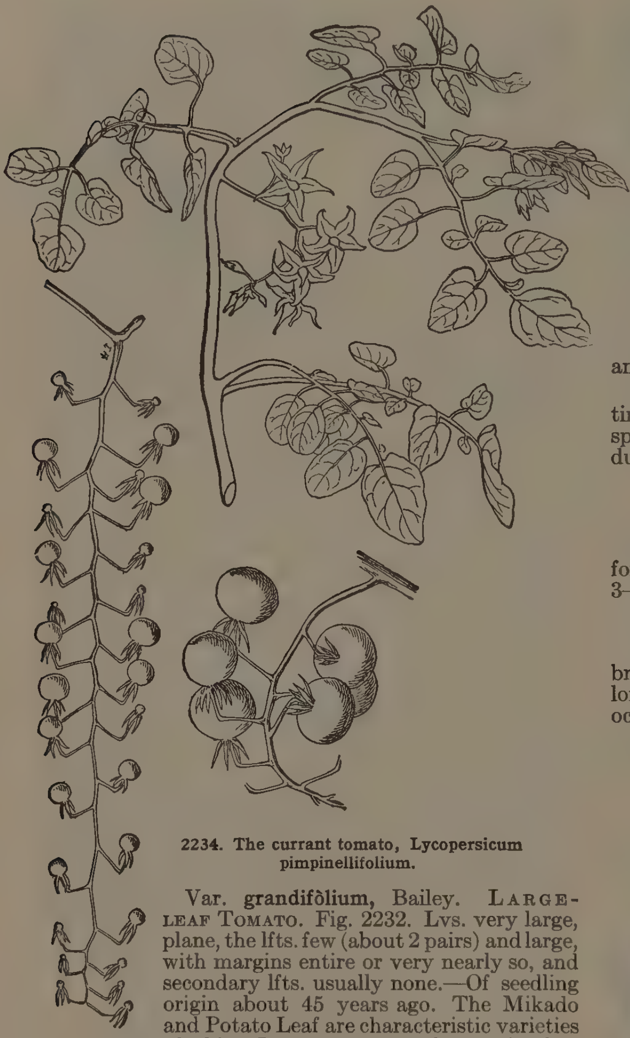
Var. **pyrifórme,** Hort. (*L. pyrifórme,* Dunal). Pear and Plum Tomato. Differs from the last only in having pear-shaped or oblong frs.—Probably occurs wild in very nearly the form seen in old gardens.



2232. Leaves of tomatoes: *1,* Lycopersicum esculentum var. grandifolium; *2,* var. vulgare; *3,* cross of the two.

Var. **válidum,** Bailey. Upright Tomato. Fig. 2233. A remarkable cultural form, of low stiff erect growth, and small, condensed, curled lvs.—Originated as a chance seedling in France about 65 years ago. Looks like a potato plant.

2233. Tree tomato, Lycopersicum esculentum var. validum.



2234. The currant tomato, Lycopersicum pimpinellifolium.

Var. **grandifòlium**, Bailey. Large-leaf Tomato. Fig. 2232. Lvs. very large, plane, the lfts. few (about 2 pairs) and large, with margins entire or very nearly so, and secondary lfts. usually none.—Of seedling origin about 45 years ago. The Mikado and Potato Leaf are characteristic varieties of this. In very young plants, the lvs. are usually entire. This race has produced crosses of commercial value with var. *vulgare*. In Fig. 2232, No. 2 is a lf. of var. *vulgare*, No. 1 is var. *grandifolium*, and No. 3 is a lf. of a hand-made cross between the two.

pimpinellifòlium, Dunal (*L. racemígerum* and *L. racemifórme*, Lange. *Solànum racemiflòrum*, Vilm., not Dunal). Currant Tomato. Fig. 2234. Plant weaker, very diffuse and twiggy, scarcely pubescent: lvs. with small ovate nearly entire lfts., and very small secondary lfts.: racemes elongating, distichous, bearing 10–40 small currant-like red berries. S. Amer.—Grown as a curiosity and for ornament. The plant makes an excellent summer cover for brush or rubbish piles. The frs. are edible, but are too small for domestic use. However, it has been intro. as a garden vegetable under the name of German Raisin tomato. It hybridizes with *L. esculentum* (see Fig. 2235). L. H. B.

LYCOPÒDIUM (Greek, *wolf-foot*). *Lycopodiàceæ*. Club-moss. Ground-pine. Running-pine. A group of pteridophytes, with erect or trailing stems, commonly used for holiday decorations.

Leaves narrow, needle- or scale-like, arranged in 4 to many ranks, and bearing spores in sporangia, located either in the axils of ordinary lvs. or in the axils of modified lvs. clustered in spikes.—About 100 species are known. The spores of some species form the officinal lycopodium powder. The plants which florists grow as lycopodiums are selaginellas. Horticulturally, the species of Lycopodium are valuable mainly as oddities. The hardy species are not always easy to get started, and the tender species need special cult. for good results. See *Selaginella*.

A. *Lvs. many-ranked.*

B. *Sporangia in the axils of unaltered lvs.*

Selàgo, Linn. Sts. erect, 3–9 in. long, dichotomously branched: lvs. ascending, hollow at base, glossy green, not reflexed. Northern hemisphere, usually in high altitudes.

lucídulum, Michx. (Fig. 2236), much like preceding, but usually larger, is more common in lowlands and has lvs. wide in the middle and erose.

squarròsum, Forst. Sts. pendulous, 1–2 ft. long, 2–3 times dichotomously branched: lvs. firm, dark green, spreading, ½–¾in. long: sporangia in the axils of reduced lvs., forming a spike. E. Indies.

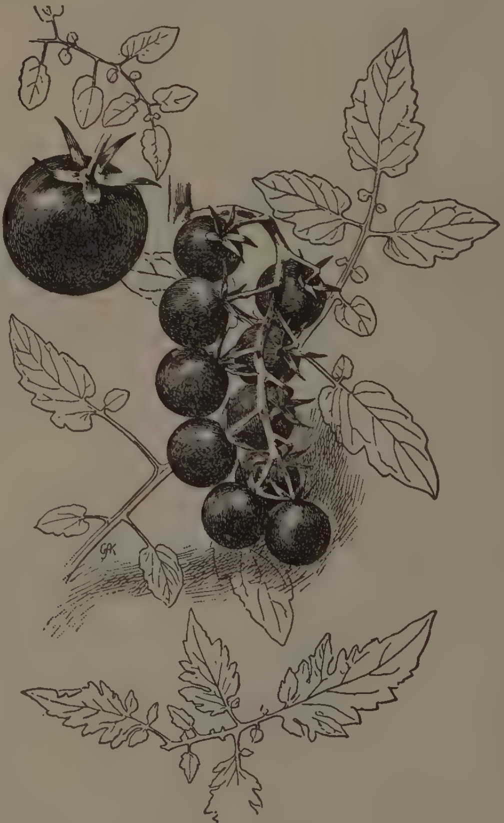
BB. *Sporangia aggregated in terminal spikes.*

C. *Sts. pendulous: lvs. acute.*

Phlegmària, Linn. Sts. ½–2 ft. long, dichotomously forked: lvs. ½–¾ in. long, ovate: spikes copious, lax, 3–6 in. or more long. Tropics of Old World.

CC. *Sts. erect, tree form.*

cérnuum, Linn. Sts. erect, reaching 3–4 ft., copiously branched: lvs. crowded, linear: spikes sessile, ¼–¾in. long, curved downward. Tropics of both hemispheres, occasionally in our Gulf states.



2235. Lycopersicum esculentum beneath; L. pimpinellifolium at top; hybrid between.

obscùrum, Linn. (*L. dendroídeum,* Michx. *L. japónicum,* Thunb.). Fig. 2236. Sts. 6–12 in. high, much-branched, forming a somewhat tree-like growth: lvs. loose, erect: spikes erect, ½–1½ in. long. Temp. N. Amer. to Japan. G.W. 9, p. 520.—The common ground-pine.

CCC. *Sts. (main ones) wide-trailing, with erect branches.*

annótinum, Linn. Sts. trailing, often several feet long, with numerous ascending branches 6–8 in. high, which bear sessile, solitary spikes. Arctic and North Temperate Zones of both hemispheres.

clavàtum, Linn. Fig. 2236. Main st. trailing to the length of several feet, usually much branched: spikes 1–4 on an elongated peduncle. Arctic and North Temperate regions of both hemispheres.—The common club-moss.

AA. *Lvs. 4-ranked, on fan-like branches.*

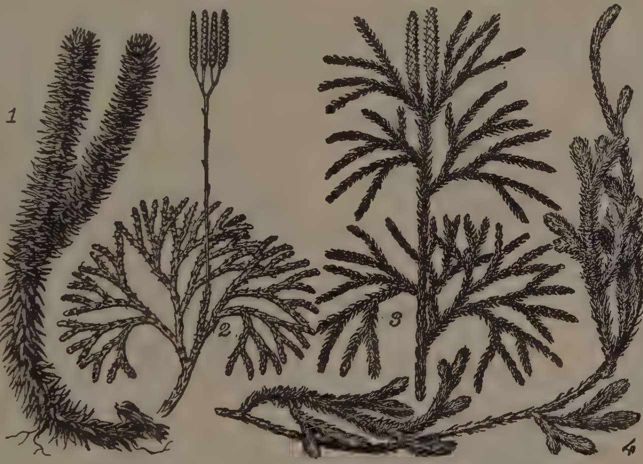
complanàtum, Linn. Fig. 2236. Sts. trailing on the surface of the ground: branches spreading out in a horizontal plane: lvs. of the under side of sts. reduced to slender, spreading, cuspidate apices: first and second forks of peduncles approximate. Northern hemisphere.—*L. Chamæcyparíssus,* R. Br., is an allied species, with sts. growing underground.

L. M. UNDERWOOD.

LYCÒRIS (named probably after a nereid in Greek mythology). *Amaryllidàceæ.* Attractive amaryllis-like bulbous plants from China and Japan.

From Amaryllis, the genus is separated by technical characters of the fl., which has few rather than many ovules in a cell, and by black rather than green seeds. Perianth funnel-shaped, somewhat irregular, with a short cylindrical tube enlarged at the top, sometimes with scales in the throat; segms. oblanceolate, clawed; stamens inserted near the throat, the filaments long and declinate; ovary 3-celled, the style filiform, the stigma minute and capitate: bulb tunicated, short-necked: peduncle solid: lvs. linear or strap-shaped: umbel many-fld., bearing red or yellow blooms.—Species about a half-dozen. At least two species are hardy in New England. Two bloom in summer and two in early autumn. Two have red fls., one has lilac or purple fls., one yellow or orange. Three have the perianth-segms. more or less recurved and fluted or crisped at the margin. In all cases the fls. appear without foliage, being borne on a scape 1–3 ft. long, in umbels of 4–12 fls., each 3–4 in. across. The white filaments and yellow anthers are conspicuous features. The lvs. make their growth, die down, and after a long rest the bulbs send up fl.-stalks alone. These plants are highly esteemed in China and Japan, and bulbs are constantly sent to the western world, but with us they seem to be wayward and uncertain, particularly as to the time of blooming. *L. aurea* reverses the custom of nature. It rests in the wet season and flowers in the dry season. How the bulbs can remain dormant during the early Chinese summer, with the thermometer at 85° in the shade and a yearly rainfall of 100 in., is a mystery. Botanically this genus is placed next to Hippeastrum, an American genus, in which the seeds are numerous in a locule, and usually flat, while in Lycoris they are few in a locule and turgid. Horticulturally Lycoris is most nearly comparable to Nerine, but the seeds of the former are black and of the latter green; in Nerine the tube is nearly or quite wanting, stamens inserted at base of segms., filaments thickened at base and 3 shorter, style obscurely tricuspidate, fls., red.

For many years, *L. aurea* has been cultivated in American gardens, although it is not a common plant. More recently, with large importations of *L. radiata,* the interest in the genus has widened. These species have the handsomer flowers, and are preferably cultivated under glass, although the bulbs are probably hardy in warm protected borders; at least they have more than once been frozen in pots at Elizabeth, New Jersey, without apparent harm. In its habitat in China, *L. aurea* rests in the wet season, and the most success in culture has been found in growing it in a warmhouse, taking care to cultivate the foliage and rest the bulbs in warmth and moist earth. The same general directions may be followed for *L. radiata.* As with all bulbs, a vigorous growth of foliage is essential to the future appearance of flowers. *L. squamigera* amd *L. sanguinea* are perfectly hardy; their leaves appear in March, mature and disappear. The flowers come in the nature of a surprise in August. The former species has a columnar scape 2 to 3 feet tall and a cluster of large, amaryllis-like flowers, of a bright rosy purple, rather attractive in the back row of a garden, but not of first rank. *L. sanguinea* has a scape 1½ to 2 feet, with small orange-red flowers, dull and curious rather than striking. The two former species have the beauty of the nerines, but the two latter have none of this resemblance. (J. N. Gerard.)



2236. Species of Lycopodium: *1*, L. lucidulum; *2*, L. complanatum; *3*, L. obscurum; *4*, L. clavatum. (After Knobel)

A. *Blooming in July and Aug.*

B. *Fls. red.*

sanguínea, Maxim: Bulb ovoid, 1 in. diam.; neck 1–2 in. long: lvs. linear. fls. red, 4–6 in an umbel on a peduncle 12–18 in. high; tube ½in. long; stamens shorter than the perianth-segms. Japan.—The only species with segms. neither wavy or reflexed. Statements that the blooming period is May and June are probably erroneous. A var. **álba** is advertised. It is said that the lvs. of this and the next appear in March; also that the fls. of *L. sanguinea* are dull brownish red.

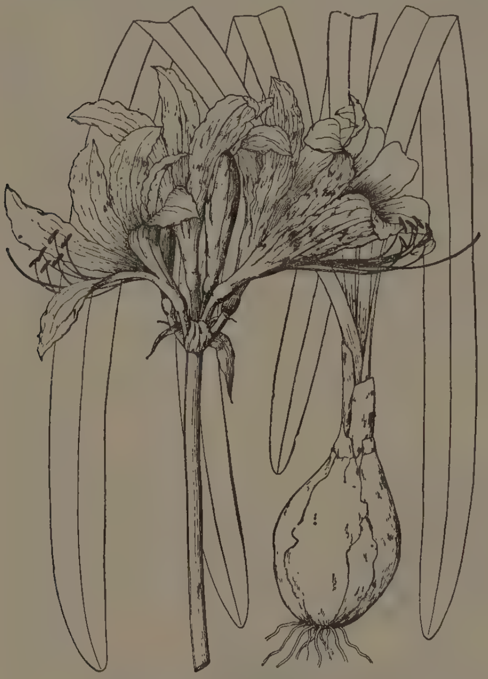
BB. *Fls. rosy lilac.*

squamígera, Maxim. (*Amarýllis Hállii,* Hort.). Fig. 2237. Bulb globose: lvs. produced in spring, 9–12 lines wide: fls. rosy lilac, banded yellow; segms. curving, much narrowed below and forming a tube nearly an inch long with truncate scales in the throat (whence the name). Japan. B.M. 7547. G.C. III. 21:137. A.G. 25:119. G.F. 3:177 (reduced in Fig. 2237).—The only fragrant kind. Var. **purpùrea,** Hort., intro. about 1898. This species is hardy in New England. It was intro. into this country by Geo. R. Hall, Bristol, R. I. (see p. 1578 for account of Dr. Hall). Apparently the most popular species.

AA. *Blooming from Sept. to Nov.*

B. *Fls. orange-colored.*

aûrea, Herb. (*Amarýllis aùrea,* L'Her. *Nerìne aùrea,* Bury). GOLDEN SPIDER LILY. Bulb 2 in. diam.: lvs. sword-shaped, 6–9 lines wide, glaucous, produced in May. China. B.M. 409. B.R. 611. G.C. III. 17:263; 18:545; 47:12, 13. Gn. 47:42.—Baker says it blooms in Aug. and has bright yellow fls., but the colored plates show orange-colored fls.



2237. Lycoris squamigera. (×⅛)

stramínea, Lindl., allied to *L. aurea,* and probably not in commerce: segms. pale straw-color with pink keel and a few scattered red dots: tube very short. China.

BB. *Fls. bright red (a white form).*

radiàta, Herb. (*Amarýllis radiàta,* L'Her. *Nerìne japónica,* Miq.). Bulb globose, 1½ in. diam.; neck short: lvs. 5–6, produced in winter, linear: stamens much longer than the perianth-segms. China and Japan. B.R. 596. A.G. 13:211.—The perianth-segms. are more recurved than in other species. The tube is very short, while in all the other kinds here described it is ½in. or more long. Var. **pùmila,** Hort., is much dwarfer than the usual forms. Var. **álba,** Hort. Pure white shaded cream. S. Japan.

Recent names in horticultural literature are: *L. incarnàta* (Sprenger, Naples). Scape 1–1¾ ft., bearing 6–12 fls., which are large and widely expanded, pale flesh-colored or bright rose and fragrant; segms. scarcely undulate, not much reflexed. Cent. China. G.W. 10:489.—*L. Sprèngeri,* Comes. Fls. rose-pink or purplish rose, on long pedicels, without perianth-tube; spathe-valves short, ovate. Probably Japan. G.C. III. 32:suppl. Dec. 27. G.W. 10:489. Allied to L. squamigera, but with shorter less pointed spathe-valves; perianth-tube ½in. long.

WILHELM MILLER.
L. H. B.†

LYGÈUM (Greek, *lugoein,* to bend). *Gramíneæ.* Spikelets 1-fld., 1½–2 in. long, with a hard, curved beak, 2–3 together at the summit of the culms, partially inclosed in a foliaceous sheath: sts. slender, wiry, 2–3 ft., from a hard scaly running rootstock: blades involute, flexuous.—Species 1, **L. Spártum,** Linn., of arid parts of the Medit. region. This species, together with *Stipa tenacissima* (which see), forms the "Esparto" of commerce, which comes mostly from Spain and Algeria.

A. S. HITCHCOCK.

LYGÒDIUM (Greek, *twining*). *Schizæàceæ.* CLIMBING FERNS. A group of ferns with twining vine-like lvs., with the sporangia borne singly under overlapping scales on the under surface of reduced portions of the lf.—Some 30 species are known from all parts of the world. They make an especially attractive growth, and do well when allowed to twine on wires or strings in a large conservatory. For cult. see *Ferns,* p. 1215.

A. *Sterile pinnules palmate. (Native hardy species.)*

palmàtum, Swartz. HARTFORD FERN. Lvs. 2 ft. or more high, twining, bearing pairs of cordate-palmate pinnules 1½–2 in. long, on short petioles; fertile pinnules 3–4-pinnatifid, with the ultimate divisions linear. Mass. to Fla. and Tenn.—Requires light moist soil and partial shade.

AA. *Sterile pinnules pinnate. (Exotic glasshouse species.)*

scándens, Swartz. Lvs. many feet long; pinnules 4–8 in. long, 2–4 in. broad, with a terminal segm. and 4 or 5 on each side, which are simple and usually ovate. India and China.—Most of the American material cult. under this name belongs to the next species.

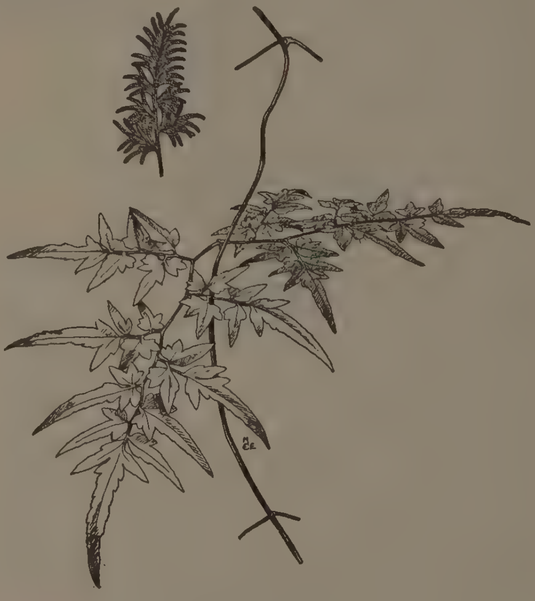
japónicum, Swartz. Fig. 2238. Lvs. many feet long; pinnules 4–8 in. long, nearly as wide, deltoid, with a pinnatifid terminal segm. and 2 or 3 lateral ones on each side, all unequal and the lowest long-stalked and pinnate in the lower part. Japan and the E. Indies. —The common species in cult.

AAA. *Sterile pinnules forked.*

circinàtum, Swartz (*L. dichótomum,* Swartz). Pinnules practically sessile, once forked, the divisions deeply 5–6-lobed, or sometimes forked twice; the sterile segms. 4–12 in. long, ½–¾in. broad, the fertile segms. very much contracted. Malaysia.

L. M. UNDERWOOD.

LYÒNIA (after John Lyon, who introduced many American plants into England; died before 1818, in Asheville, N. C.). Syn., *Xolísma.* *Ericàceæ.* Ornamental shrubs, sometimes grown for their white flowers and dense foliage.



2238. Lygodium japonicum. (×⅛)

Deciduous or evergreen: lvs. alternate, short-petioled, entire or serrulate: fls. fascicled or panicled, white; calyx-lobes 4–5, valvate; corolla globular or urceolate, pubescent; stamens 8–10; anthers oblong, truncate at the apex; disk 8–10-lobed: caps. 4–5-valved, with ribs at the sutures and intruded at the apex; seeds numerous, with a loose reticulate testa.—About 10 species in E. N. Amer., W. Indies and Mex. Allied to Pieris and often included under Andromeda.

The lyonias are much-branched shrubs with dull green medium-sized foliage and small white flowers in clusters or panicles. Only the deciduous *L. ligustrina* is hardy North, but is less desirable than other hardy species of allied genera. It prefers moist peaty soil, while the evergreen tender *L. ferruginea* thrives best in a sandy, well-drained soil. Cultivated and propagated like leucothoë and pieris.

ligústrina, Muhl. (*Xolísma ligústrina,* Brit. *Andrómeda paniculàta,* Ait. *A. ligústrina,* Muhl. *A. parabólica,* Duham. *L. paniculàta,* Nutt.). Deciduous, much-branched shrub, to 10 ft.: lvs. obovate to oblong-lanceolate, entire or obscurely serrate, pubescent beneath, 1–2 in. long: fls. in leafless racemes, forming terminal panicles; corolla globose, whitish, ⅙in. long. May–July. Canada to Fla., west to Tenn. and Ark. B.B. (ed. 2) 2:691. Var. **foliosiflòra,** Fern. Racemes less crowded, often elongated, conspicuously leafy-bracted. Var. **pubéscens,** Rehd. (*Andrómeda ligústrina* var. *pubéscens,* Gray. *A. tomentòsa,* Hort., not Dum.-Cours.). A form with soft dense pubescence.

ferrugínea, Nutt. (*Xolísma ferrugínea,* Heller. *Andrómeda ferrugínea,* Walt.). Evergreen shrub or small tree: lvs. cuneate, obovate to oblong, with revolute margin, scurfy when unfolding, especially below, 1–2 in. long: fls. nodding, globular, white, in clusters in the axils of the upper lvs. Feb., March. S. C. to Fla. S.S. 5:234. L.B.C. 5:430.—Handsome evergreen shrub, but rarely cult., hardy only S. Var. **arboréscens,** Rehd. (*Andrómeda rígida,* Pursh). Of vigorous growth, more rigid and with crowded lvs., growing into a small tree. Var. **fruticòsa,** Rehd. (*Xolísma fruticòsa,* Nash. *A. rhomboidàlis,* Nouv. Duh.). Shrubby: lvs. sparser, conspicuously reticulated. ALFRED REHDER.

LYONOTHÁMNUS (*Lyon's shrub;* named for W. S Lyon, who sent specimens to Asa Gray from Santa Catalina Island, California). *Rosàceæ.* Ornamental woody plant grown for its handsome foliage and the large clusters of white flowers.

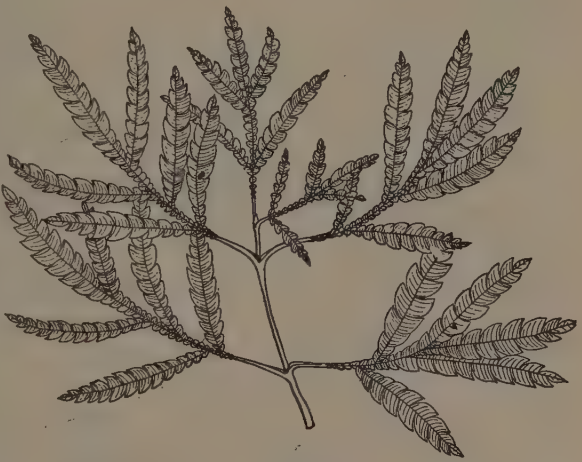
Evergreen shrub or small tree: lvs. opposite, petioled, lanceolate and nearly entire or pinnate: fls. perfect, in terminal flat corymbs; calyx with 2–3 bractlets at the base; tube hemispherical; lobes 5; petals 5, orbicular; stamens 10, inserted at the margin of the 10-lobed, lanate disk: carpels 2, developing into woody dehiscent caps., each with 4 ovate-oblong seeds.—One species on the islands off the coast of S. Calif. The pinnate-lvd. variety is grown to some extent in N. and S. Calif. and is locally known as "ironwood" or "palo fierro." It is difficult to prop.; seeds are rarely obtainable and only a small percentage germinate; cuttings are usually not successful, but it is said that basal sprouts root more readily

floribúndus, Gray. Usually shrubby: lvs. of the typical form lanceolate, crenulate or subentire, dark green and lustrous above, yellowish green and glabrous or pubescent below, 4–8 in. long and ½–¾ in. wide: fls. white, ⅙–¼in. across in large corymbs 4–8 in. wide. June, July. Various transitional forms between the foliage of the type and that of the following variety are shown in Zoe. 1:5. Var. **asplenifòlius,** Brandegee (*L. aspleniifòlius,* Greene). Fig. 2239 (after Hall). Sometimes tree-like, to 75 ft.: lvs. pinnately divided into 3–8 incisely lobulate segms. S.S. 4:297.—This variety is quite plentiful on the island of Santa Cruz and also on Santa Rosa and is cult. for its handsome fern-like foliage; the type, which is found only on the island of Santa Catalina, is less handsome and was never brought under cult. ALFRED REHDER.

LYSICHÌTUM (Greek, a *loose* or *free cloak;* probably referring to the spathe). Also written *Lysichiton. Aràceæ.* A genus of one species; a hardy plant resembling the skunk cabbage, which has been offered by dealers in native plants.

Nearly stemless swamp herb with large lvs. from a thick horizontal rootstock: spathe peduncled, sheathing at base, with a broad colored lamina or none, at first enveloping the cylindrical spadix, which becomes long-exserted upon a stout peduncle; fls. perfect, crowding and covering the spadix; perianth 4-lobed; stamens 4; ovary 2-celled, 2-ovuled; ovules horizontal, orthotropous: fr. a 2-seeded berry, immersed in the spadix.

camtschatcénse, Schott. Lvs. 1–4 ft. long, 3–15 in. wide, oblong-lanceolate: peduncle shorter than the lvs. May, June. E. Siberia, Japan, Alaska, Ore., Calif. B.M. 7937. G.C. III. 27:219; 57:301. G.M. 48:330. L. H. B.



2239. Lyonothamnus floribundus var. asplenifolius.

LYSILÒMA (Greek, probably meaning *free border*). *Leguminòsæ.* About a dozen unarmed trees and shrubs of the American tropics, scarcely cult. They bear bipinnate lvs., and fls. in heads or in cylindrical spikes; petals united into a 5-lobed corolla: pods straight and flat, the valves opening away from the persistent sutures. Some of these plants are often called acacias. *L. acapulcénsis,* Benth. (*Acàcia acapulcénsis,* Kunth). Tree-like: pinnæ 8–9 pairs, the lfts. very many, oblong-linear and pubescent, glands 2 or 3 between some of the pinnæ; fls. white in cylindrical axillary spikes; stamens many, monadelphous. Mex. Reported in Santa Barbara.—*L. bahaménsis,* Benth. (*L. latisíliqua,* Gray, not Benth.). WILD TAMARIND. Tree, to 50 ft., wide-spreading: pinnæ 3–5 pairs; lfts. 20–50; blades of the latter oblong or oblong-lanceolate, acute, glabrous or nearly so: fl.-heads white, less than ½in. diam.: pod oblong, flat and undulate. S. Fla., Bahamas, Cuba.—*L. Schiedeàna,* Benth. Pinnæ 6–9 pairs: lfts. 40 pairs, linear, obtuse, glabrous or minutely puberulent; stipules semi-ovate to falcate: fls. white, in 1–3 axillary pedunculate heads. Mex.—*L. divaricàta* (*Mimòsa divaricàta,* Jacq.) is a doubtful species with synonymy apparently yet to be cleared up. L. H. B.

LYSIMÀCHIA (probably after King Lysimachus). *Primulàceæ.* LOOSESTRIFE. Erect or creeping leafy herbs grown in damp wild gardens and borders.

Leaves opposite or whorled, entire, usually black-punctate: fls. spicate, racemose or solitary, with a rotate or campanulate, 5-parted corolla with an equal number of slightly monadelphous stamens opposite the lobes: caps. 1-loculed, with many seeds on a central placenta. —Over 100 species found in temperate and subtropical regions of all parts of the world. Only a few in cult., and these all perennials. They differ from related genera in the absence of staminodia between the stamens, which are usually slightly united. Revision, Knuth in Das Pflanzenreich, hft. 22, p. 256 (1905).

The loosestrifes are of easy culture, thriving best in moist situations. Propagation is by division in late autumn or early spring.

KEY TO THE SPECIES.

A. *Plant shrubby*...................... 1. **Hillebrandii**
AA. *Plant herbaceous.*
B. *Color of fls. yellow.*
C. *St. creeping: lvs. round-ovate, obtuse*...................... 2. **Nummularia**
CC. *St. erect: lvs. ovate-lanceolate or linear, mostly acute.*
D. *Fls. in dense axillary pedunculate clusters*.................. 3. **thyrsiflora**
DD. *Fls. in dense terminal clusters surrounded by large lvs.: cauline lvs. very small*....... 4. **paridiformis**
DDD. *Fls. racemose or axillary.*
E. *Whole plant glabrous or nearly so: fls. 3–6 lines broad.*
F. *The fls. in terminal racemes*................ 5. **terrestris**
FF. *The fls. axillary*......... 6. **quadrifolia**
EE. *Whole plant densely pubescent: fls. 9–12 lines broad.*
F. *Calyx 2 lines long, dark-margined: fls. in leafy panicles*.............. 7. **vulgaris**
FF. *Calyx 3½–5 lines long, not dark-margined: fls. axillary*.................. 8. **punctata**
BB. *Color of fls. white: pedicels short.*
C. *Lvs. opposite, somewhat connate*.. 9. **Ephemerum**
CC. *Lvs. alternate, attenuate at base.*
D. *Blades glaucous beneath, oblong-linear* ....10. **barystachys**
DD. *Blades green, lanceolate or ovate-lanceolate.*
E. *Plant glabrous: lvs. oblong*..11. **Fortunei**
EE. *Plant puberulent: lvs. ovate*..12. **clethroides**
BBB. *Color of fls. red, blue or purple.*
C. *Calyx-lobes acuminate, slightly shorter than the entire-lobed corolla*.....................13. **Leschenaultii**
CC. *Calyx-lobes obtuse, much shorter than the usually erose-lobed corolla*....................14. **nutans**

1. **Hillebrándii,** Hook. Shrub 1½–8 ft. high, densely branched, often red-tomentose: lvs. alternate, subopposite or subverticillate, lanceolate, ovate or linear, acuminate at each end, coriaceous, short-petioled: calyx-lobes acuminate; corolla reddish purple, campanulate; lobes obovate, obtuse; stamens included. Hawaiian Isls.

2. **Nummulària,** Linn. Moneywort. Creeping Charlie. Creeping Jenny. Glabrous, forming large patches: lvs. opposite, rarely cordate, petiolate, ½–1 in. long: fls. 8–12 lines broad; sepals cordate or lanceolate, acute, half as long as the 5 oval, sparingly dark-dotted corolla-lobes; filaments glandular. June–Aug. Eu.; also naturalized extensively in the E. U. S. R.H. 1891, p. 303; 1899, p. 21. B.B. 2:589.—Very useful for rustic vases and baskets, also for carpeting ground in shady places. Sometimes a low weed in lawns. Var. **aùrea,** Hort. Lvs. all or in part bright yellow.

3. **thyrsiflòra,** Linn. (*Naumbùrgia guttàta*, Moench). Glabrous: st. simple, 1–3 ft. high: lvs. opposite, lanceolate: fls. small, 2–3 lines long, yellow, in short pedunculate axillary heads; calyx-lobes narrow; corolla-lobes linear, dotted. Swamps, N. E. N. Amer. and Eu. B.M. 2012.—Prefers shallow water.

4. **paridifórmis,** Franch. Glabrous: st. verticillately branched above: upper lvs. large, 3–5 in. long, whorled, sessile, elliptic or obovate-lanceolate, acuminate, glaucous beneath; lower very small, opposite: fls. large, yellow, condensed into a dense cluster surrounded by large lvs., sometimes also axillary clusters; sepals lance-subulate; corolla campanulate; lobes lanceolate, acute; stamens included. China. B.M. 7226.

5. **terréstris,** BSP. (*L. stricta*, Soland.). Simple or branched, glabrous, 8 in. to 2 ft. high: lvs. opposite, lance-linear, acute at both ends, glaucous beneath, scarcely veiny, 1–3 in. long: fls. 3–5 lines broad, very numerous, in a distinct, elongated, terminal raceme; pedicels 3–9 lines long, slender; corolla yellow, the lobes elliptical, streaked with dark lines; filaments glandular. Common on moist ground in the E. U. S. B.M. 104 (as *L. bulbifera*). B.B. 2:588. Blanchan Nat. Gard., p. 324.—Often bears bulblets in the lf.-axils after flowering.

6. **quadrifòlia,** Linn. Usually simple, sometimes slightly pubescent, 1–3 ft. high: lvs. verticillate, in 3's–4's, rarely some opposite, lanceolate, oblong or ovate, acute, 1–4 in. long, green beneath, veiny: fls. axillary, 3–6 lines broad, on very slender pedicels, which are ½–1½ in. long; calyx and corolla as in *L. terrestris*. Dry soil. E.U.S. B.B. 2:588.

7. **vulgàris,** Linn. Common Yellow Loosestrife. Tall and erect, 2–3 ft. high, and stout; branched above, downy, especially on the st.: lvs. verticillate, in 3's–4's, ovate-lanceolate or lance-oval, acute at both ends, nearly sessile: fls. in the upper axils, or densely paniculate at the summit; calyx often dark-margined; corolla large, the lobes broad, glabrous. Eu., Asia. R.H. 1891, p. 303.; 1899, p. 21.—Very showy when grown in clumps.

8. **punctàta,** Linn. (*L. verticillàta*, Bieb.). Tall and stout: lvs. verticillate, in 4's, lanceolate, ovate or cordate-ovate, acute, subsessile: corolla-lobes oval, denticulate, glandular-ciliate, acute; stamens united. Very similar to *L. vulgaris*, but differs in the larger calyx-lobes not dark-margined: fls. in axillary, equidistant whorls, not paniculate, and corolla glandular. Eu., W. Asia. B.M. 2295 (as *L. verticillaris*). G.M. 57:111.

9. **Ephémerum,** Linn. Smooth: lvs. opposite, glaucous, elongate-lanceolate, obtuse, connate and somewhat decurrent: raceme long, terminal: bracts equaling the short (2–4 lines long) pedicels; fls. white, often tinged with purple; calyx-lobes ovate, obtuse; corolla-lobes ovate, obtuse, twice as long as the calyx; stamens slightly exserted. S. Eu. B.M. 2346. R.H. 1891, p. 303.

10. **barýstachys,** Bunge (*L. brachýstachys*, Hort.). St. strict, simple, hispid and leafy above: lvs. few, alternate, linear-oblong, abruptly acute, attenuate at base, appressed puberulent, glaucous beneath: raceme at first nodding, dense, terminal, spike-like: bracts exceeding the short pedicels: fls. white; calyx shorter than the corolla; the lobes ovate, obtuse, ciliolate, membranous-margined; corolla-lobes oblong-linear, obtuse, longer than the stamens. China. R.H. 1881:90.

11. **Fórtunei,** Maxim. Glabrous: lvs. alternate, oblong-lanceolate, acuminate or mucronate; base acuminate, cartilaginous-margined: raceme dense: bracts equaling the short (1–2 lines long) pedicels: fls. white; calyx broadly campanulate; the lobes obtuse, mem-

branous-margined; corolla longer; the lobes ovate, obtuse. China, Japan.

12. **clethroìdes,** Duby. Tall and stout, 3 ft. high or less, sparingly pubescent, rarely glabrous: lvs. opposite, large, 3–6 in. long, and sessile, broadly lanceolate, attenuate at each end, radical spatulate: fls. ½in. diam., in a very long, slender, terminal spike; pedicels short, bracts subulate; fls. white; calyx blackish, shorter than corolla; lobes lanceolate, acute, membranous-margined; corolla-lobes ovate-lanceolate, obtuse; stamens included. China, Japan. Mn. 8, p. 141.—Fine for cut-flowers, also for border.

13. **Leschenaùltii,** Duby. Somewhat branched: lvs. opposite or verticillate in 3's, lanceolate, acuminate, glabrous, short-petioled: raceme dense, terminal: bracts shorter than the pedicels: fls. blue or purple; calyx much shorter than corolla; lobes narrow, acuminate; corolla campanulate; lobes obovate, obtuse, entire; stamens unequal, exserted. Mountains of India. R.H. 1891, p. 303.

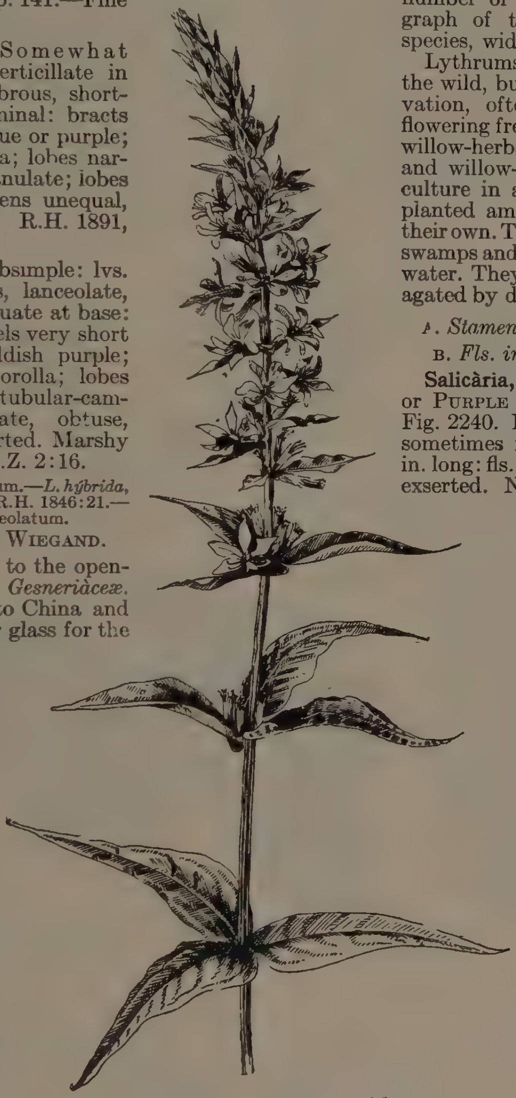
14. **nùtans,** Nees. St. subsimple: lvs. opposite or verticillate in 3's, lanceolate, acuminate, very smooth, attenuate at base: racemes dense, terminal; pedicels very short at first; fls. deep bright reddish purple; calyx one-third as long as corolla; lobes lance-linear, obtuse; corolla tubular-campanulate; lobes lance-spatulate, obtuse, erose-denticulate; stamens exserted. Marshy regions, S. Afr. B.M. 4941. G.Z. 2:16.

L. ciliàta, Linn.=Steironema ciliatum.—*L. hýbrida,* Michx.=Steironema lanceolatum. R.H. 1846:21.—*L. lanceolàta,* Walt.=Steironema lanceolatum.

K. M. Wiegand.

LYSIONÒTUS (name refers to the opening of the caps. at the back). *Gesneriàceæ.* Six to 10 small shrubs, India to China and Japan, grown sometimes under glass for the blue or white fls., but apparently not in the trade. Some or all are epiphytic; glabrous: lvs. opposite or in 3's: fls. in few- to many-fld. inconspicuously bracted cymes; sepals narrow; corolla tubular and straight, inflated at middle, 2-lipped; stamens 2 perfect and 2 or 3 staminodia; the filaments flattened; disk ring-like: caps. very narrow, 2-valved. *L. serràta,* Don (*L. ternifòlia,* Wall.), is about 1 ft. high: lvs. elliptic or lanceolate, serrate or sinuate: fls. pale lavender or white and purple-veined, an inch or two long, about 10 or less in peduncled clusters. Subtrop. Himalayan region, 2,000–7,000 ft. B.M. 6538. *L. carnòsa,* Hemsl. Dwarf shrub with straight rigid branches: lvs. in 3's, short-stalked, thick and fleshy, ovate, few-toothed: fls. 1½ in. long, white tinged lilac, in pairs in the upper axils. China. *L. warleyénsis,* Hort. Little shrub, 9 in. high: lvs. opposite or in 3's, oblong to lanceolate, few-toothed, fleshy, white beneath, the petiole crimson: fls. white with 3 purple lines, 2 in. long. China.—A beautiful plant, of very recent intro. *L. carnòsa,* Hemsl., is a dwarf shrub from China, glabrous, with straight and rigid green branches: lvs. in 3's, short-stalked, fleshy, ovate, to 2 in. long, dentate: fls. 1¼ in. long, white tinged lilac, in pairs in the upper axils.

L. H. B.



2240. Lythrum Salicaria. (×⅕)

LÝTHRUM (Greek, *blood;* possibly from the styptic properties of some species, or the color of the flowers). *Lythràceæ.* Herbs or subshrubs, of which three are cultivated in hardy borders.

Branches 4-angled: lvs. opposite, or alternate, rarely whorled, linear-oblong or lanceolate, entire: fls. rosy purple or white, in the upper axils usually solitary, lower down more or less whorled; calyx-tube cylindrical, 8–12-ribbed; petals 4–6, obovate; stamens as many or twice as many: caps. 2-celled, with an indefinite number of seeds.—Koehne in his monograph of the Lythraceæ recognizes 24 species, widely scattered.

Lythrums grow about 2 to 3 feet high in the wild, but improve markedly in cultivation, often attaining 4 to 5 feet and flowering freely. Some of them are called willow-herbs from their strong, erect habit and willow-like leaves. They are of easy culture in any moist soil, and are usually planted amid shrubbery, where they hold their own. They are denizens of low grounds, swamps and meadows, often growing in the water. They flower in summer and are propagated by division. (F. W. Barclay.)

A. *Stamens twice as many as the petals.*

B. *Fls. in an interrupted, leafy spike.*

Salicària, Linn. (*L. ánceps,* Hort). Spiked or Purple Loosestrife. Black Blood. Fig. 2240. Height 2–3 ft.: lvs. opposite or sometimes in whorls of 3, lanceolate, 2–3 in. long: fls. purple; stamens barely if at all exserted. North temperate regions. Austral. B.B. 2:473. G. 3:622.—Best of the genus. Koehne has made 29 botanical varieties and subvarieties of this one species. Var. **supérbum** and var **ròseum,** Hort., have rose-colored fls. Var. **ròseum supérbum,** Hort., may be the same as the preceding varieties. It is large-fld., rose-colored, more robust (4–6 ft.); somewhat later in blooming. July–Sept.; a clearer, finer colored form than the species. It is generally sold as *L. roseum superbum* (not as a variety of *L. Salicaria*). G. 29:167. Var. **atropurpùreum,** Hort., is a fine variety producing large spikes of very dark rose-purple fls. Var. **tomentòsum,** DC. Lvs. tomentose. Var. **ròseum,** Perry's Variety, has cherry-red fls., larger and upon longer spikes. Excellent for the bog-garden.

BB. *Fls. solitary in the upper axils, racemose.*

virgàtum, Linn. (*L. austriacum,* Jacq.). Lower lvs. opposite, rounded at the base: calyx not bracted: fls. smaller than *L. Salicaria* and rose-purple. Eu., N. Asia.—Of good landscape value and compact growth: the brightest colored kind of lythrum. Var. "Rose Queen" is much catalogued.

AA. *Stamens not more numerous than the petals.*

alàtum, Pursh. Two ft. tall: half shrubby, with twiggy 4-angled branches: lvs. mostly alternate, obtuse: stamens exserted: fls. crimson-purple. June to Sept. N. Amer.

Wilhelm Miller.
A. C. Hottes.†

M

MAÀCKIA (after Richard Maack, Russian naturalist who explored northeastern Asia; 1825–1886). *Leguminòsæ.* Trees grown out-of-doors for their handsome foliage and the panicles of white flowers.

Deciduous: winter-buds free, scaly: lvs. alternate, odd-pinnate, with entire, opposite or nearly opposite short-stalked lfts.: fls. white, papilionaceous, in dense upright racemes, usually several in terminal panicles; calyx campanulate, 5-toothed; stamens 10, more or less connate: pod linear-oblong, compressed, with 1–5 seeds.—Two or three species in E. Asia; usually united with Cladrastis, but easily distinguished even without fls. by the free scaly winter-buds and the opposite lfts.; in Cladrastis the winter-buds are naked and inclosed in the base of the petiole and the lfts. are alternate.

The maackias are small or medium-sized trees or rarely shrubs with rather large pinnate foliage and upright dense panicles of small white flowers appearing in summer. They are hardy North and not particular as to the soil, but prefer a warm and sunny position to bloom well. Propagation is by seeds sown in spring or by root-cuttings like cladrastis.

amurénsis, Rupr. (*Cladrástis amurénsis,* Koch). Tree, to 40 feet.: lfts. 7–11, elliptic- or oblong-ovate, rounded at the base, glabrous, 2–3 in. long: racemes erect, dense-fld., usually panicled, 4–8 in. long: fls. whitish, about ⅓in. long: pod 1½–2 in. long. July, Aug. Manchuria. B.M. 6551. Gn. 24, p. 265; 33, p. 444; 44, p. 60. F.S.R. 3, p. 23. G. 6:379. H.F.II. 13:298. Var. **Buèrgeri,** Schneid. (*Cladrástis amurénsis* var. *floribúnda,* Shirasawa), from Japan, has the lvs. pubescent beneath. S.I.F. 1:50.

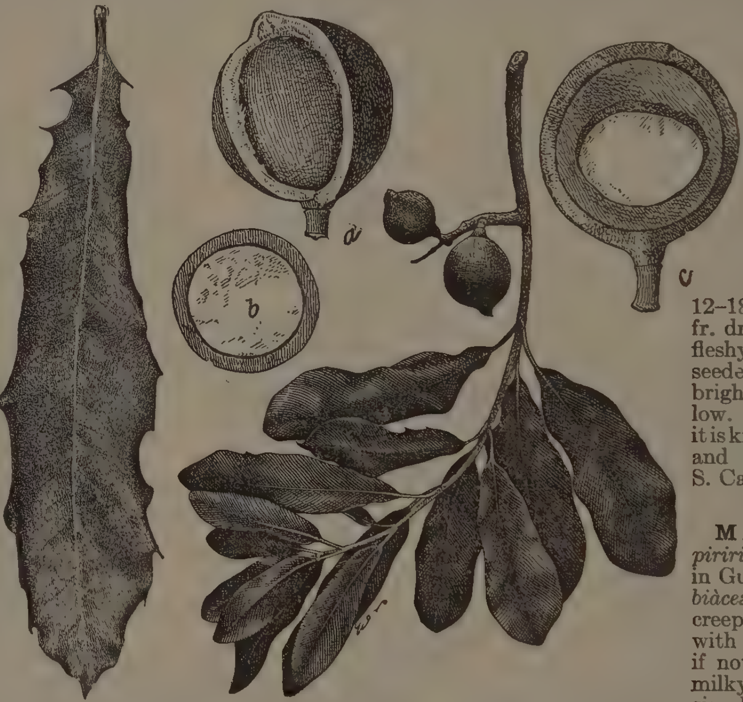
M. Tashiròi, Makino (Cladrastis Tashiroi, Yatabe). Shrub: lfts. 9–15, nearly glabrous, ½–1½ in. long: fls. smaller; standard not emarginate. Japan. Tokyo Bot. Mag. 6:10.

Alfred Rehder.

MÀBA (native name). *Ebenàceæ.* Some 60–70 species of trees and shrubs in the warmer regions of the world, mostly with hard ebony-like wood. Closely allied to Diospyros, the floral parts mostly in 3's instead of 4's or 5's, stamens usually 9 but varying from 3 to many, ovary 3- or 6-celled: lvs. usually smaller than in Diospyros. Lvs. alternate, simple and entire: fls. axillary, solitary or in short cymes, usually diœcious; corolla bell-shaped or tubular; styles 3, or 1 and 3-parted: fr. a berry, ovate or globose, 1–6-seeded. Two species have been intro. S. as ornamental subjects.

natalénsis, Harv. Much-branched evergreen shrub, with flexuous branches: lvs. wide, ovate, oblong or elliptical, obtuse, dark green above, paler beneath, glabrous, netted-veined beneath: female fls. solitary; calyx cup-shaped, glabrous, entire; abortive stamens 6–7; ovary glabrous: berries in large bunches, black. Natal; offered in S. Fla.

sandwicénsis, A. DC. Attractive tree, 20–40 ft.: lvs. thick and leathery, dull green, elliptic or ovate-oblong, distichous: fls. single or the males rarely clustered, small, the corolla 3-toothed and densely hairy on upper half; male fls. with 12–18 free stamens: fr. dry or somewhat fleshy, usually 1-seeded at maturity, bright reddish yellow. Hawaii (where it is known as "lama") and Fiji; offered in S. Calif. L. H. B.



2241. Macadamia ternifolia; a, nut showing dehiscence of husk; b, cross-section; c, longitudinal section. (Spray ×⅓, separate leaf ×¼, nuts ×1)

MABÈA (from *piriri-mabe,* the name in Guiana). *Euphorbiàceæ.* Climbing or creeping shrubs, some with economic uses, if not in cult. Juice milky: lvs. alternate, simple, pinnately veined, short-petioled, pubescent: fls. monœcious, apetalous; staminate calyx 3–5-lobed, lobes imbricate; stamens 10–70; styles connate into a long, slender column, free above; ovary 3-celled, 1 ovule in each cell; seeds carunculate.—Thirty species in Trop. S. Amer. Related to Sapium and Stillingia. *M. fistulòsa,* Mart., is used in Brazil for pipe-stems and in medicine. This species and *M. occidentàlis,* Benth. (*M. Pirìri,* Benth.), yield some rubber. J. B. S. Norton.

MACADÀMIA (after John Macadam, M.D., secretary Philosophical Institute, Victoria, Australia). *Proteàceæ.* A small group of Australian trees or tall shrubs, of which *M. ternifolia* is cultivated for its edible fruit, and is the best known.

Leaves verticillate, entire or serrate: fls. hermaphrodite, pedicellate in pairs or scattered, in terminal or axillary racemes or panicles; perianth regular or nearly so; stamens inserted a little below the blades, filaments short; ovary sessile, with a long straight style, ovoid or clavate at end, stigma small; ovules 2: fr. globular; seeds either solitary and globular or 2 and hemispherical; testa membranous.

ternifòlia, F. Muell. QUEENSLAND NUT. Fig. 2241. In its typical form this is a tall tree, with dense foliage, the young branches and infl. minutely pubescent: lvs. sessile or nearly so, glabrous and shining, in whorls of 3 or 4, oblong or lanceolate, acute or obtuse, serrate or entire, from a few inches to 1 ft. long: racemes almost as long as the lvs.; perianth minutely pubescent or glabrous; ovary villous, style end clavate: fr. with a 2-valved leathery exocarp, endocarp smooth and shining, thick and very hard; seeds 1 and globular or 2 and hemispherical. Queensland and New S. Wales. G.C. 1870: 1181.—Other species are *M. Whèlanii*, Bailey, Queensland, a medium-sized tree; *M. preálta*, Bailey, Queensland, sometimes lofty, wood of reddish color, useful for cabinet-work, as is that of nearly all species; *M. Lòwii*, Bailey, Queensland, the Maroochie nut, tree 15–20 ft. high, forming 6–20 woody sts. from a hard, spreading rhizome, and with a pointed, ribbed fr. about 1 in. diam., edible; *M. mìnor*, Bailey, Queensland, the small-fruited Queensland nut, small tree or large shrub, sending up numerous sts. from base, lvs. up to 2 in. long, fr. up to 1 in. diam., velvety outside, sometimes inversely conical in form, edible.—The Queensland nut is cult. to a small extent in S. Calif. and S. Fla., and has recently fruited in Cuba, where it appears to thrive. It is slow in growth, rarely coming into bearing before 6–8 years of age, and delights in a deep rich loamy soil, containing plenty of moisture. It has succeeded in Calif., however, with very little water, though its growth under such conditions is naturally slower. Several distinct forms of the tree are thought to exist, but the typical one is upright, sometimes 50 ft. in height, with a clean trunk and a deep green umbrageous head of foliage. The nuts are about 1 in. diam., with a hard shell about ⅛in. thick, which is rather difficult to crack. The kernel is ½in. or more in diam., white, crisp, and of a flavor resembling that of the Brazil nut (*Bertholletia excelsa*) but milder and more delicate. The tree is evergreen, and even while young withstands slight frosts (perhaps 26° F.) uninjured. For its ornamental appearance alone it is worthy of a place in parks and gardens. Its close-grained reddish timber is considered of value for cabinet-making. Prop. is usually by seeds, which may be stratified in sand or planted singly in pots of light, porous, sandy soil. If planted during the summer or if artificial heat is provided they will usually germinate within a month or 6 weeks; otherwise they may take a long time. When the seedlings make their appearance water should be given sparingly, as they are likely to damp-off if kept too wet. Plants may be set out in the open ground when about 18 in. high, and should be staked to keep them shapely. Practically no pruning is required. A promising tree for intro. into the American tropics and the warmest parts of the U. S. F. W. POPENOE.

MACARÁNGA (the Madagascar name). *Euphorbiàceæ.* Trees or shrubs, rarely cult. in greenhouses or in tropical lands. Lvs. alternate, simple, entire, palmately nerved, peltate: fls. diœcious or monœcious, inconspicuous, apetalous; calyx valvate; anthers 3–4-celled; styles free, short, undivided; ovary 1–3-celled, 1 ovule in each cell. Species more than 100 in the Old World tropics. Related to Mallotus and Mercurialis. Prop. and cult. similar to codieum. *M. Porteàna*, André (*Máppa Porteàna*, Hort.), of Philippine Isls. A very striking plant, with orbicular-ovate, strongly ribbed lvs. nearly 3 ft. wide, and small fls. in red panicles, is in cult. in Eu. R.H. 1888, p. 176. G.C. III. 16:284. B.M. 7407. *M. kilimandschárica*, Pax, resembles *M. Porteana* in habit, but is smaller, with peltate lvs., bronze-colored when young. German E. Afr. The other species appear not to be in cult. J. B. S. NORTON.

MACFADYÈNA (Dr. J. Macfadyen, author of a flora of Jamaica). *Bignoniàceæ.* As defined by Bentham & Hooker, 21 species of tall-climbing shrubs in Trop. Amer. and extra-Trop. S. Amer., including Dolichandra; as defined by Schumann in Engler & Prantl, 3 species in S. Amer., excluding Dolichandra and others. The plant in the trade (offered in S. Calif.) is **M. cynanchoìdes,** Morong (or **Dolichándra cynanchoìdes,** Cham.). It is a glabrous liana of S. Brazil and Argentina: branches slender and terete: lvs. opposite, of 2 oblong, ovate or ovate-lanceolate acute entire lfts. and usually a 3-parted tendril at end: fls. single or few on the peduncle, red; calyx cut to the middle, spathaceous; corolla long, tubular (2¼ in. long); stamens 5, one being a rudiment, exserted: stigma exserted: fr. a caps. 3 in. long and ¾in. wide.

M. dentàta, Schum. (Bignonia Fraseri, Hort. B. Tweediana, Griseb., not Lindl. M. Tweediana, Griseb.). A strong climber, self-clinging, with 3-forked tendrils: lfts. 2, ovate to ovate-oblong, short-acuminate, dentate, lepidote on both sides, glossy above, 1½–2½ in. long: fls. axillary, solitary; calyx split; corolla tubular funnelform, yellow, 2½ in. long, outside lepidote; ovary lepidote: caps. linear, 7–12 in. long. Brazil to Argentina. Intro. in S. Calif.

L. H. B

MACHÆRIUM TIPU: *Tipuana speciosa.*

MACHINERY AND IMPLEMENTS. The American farmer is known by his tools and machinery. Labor costs much and land relatively little. The American is inventive. The result is that there is a tool to expedite and lighten almost every labor. The effort of each man is multiplied. Not only are the American tools numerous and adapted to almost every agricultural labor, but they are trim, light and comely in design.

A tool is properly a hand implement, used to facilitate mere manual labor. A machine is a contrivance, usually more elaborate, that multiplies and transmits power or motion. Yet tools and machines merge so completely that it is impossible to make a definite category of one or the other. The word implement is more generic, and applies to any intermediary device by means of which a man accomplishes a given work. The phrase "agricultural implements," as used by tradesmen, usually refers to both tools and machines. In general discussions the word tool is used somewhat indefinitely, as in this sketch; but even then it does not include complicated machinery.

The machines and tools used by horticulturists may be thrown into five general categories:

1. To till the land, as plows, harrows, rollers, cultivators, weeders, hoes, rakes. See *Tillage.*
2. To facilitate various handwork, as seed-sowers, transplanters, markers, pruning implements, and most greenhouse devices.
3. To facilitate the destruction of insects and fungi, as fumigators, syringes, spraying devices. See *Diseases and Insects*, Vol. II.
4. To transport, as carts, barrows.
5. To aid in packing and sorting. See article on *Packing.*

In the multiplicity of tools, one is often at a loss what to purchase. The buyer should have a definite idea of the kind of labor that he needs to have performed and he should then consider how well adapted the tool may be to perform it. Once purchased, the tools should be cared for. A tool-shed or -room is the greatest convenience and often good economy. Labor is expedited and annoyance saved if each tool has its place. Every farm or garden should be provided with a room that can be warmed in cold weather, in which repairs can be made on machinery and implements. No farm establishment is complete without such a room. The care of tools not only contributes to the longevity and usefulness of the implements themselves, but it sets distinct ideals before the farmer and thereby is a means of educating him. The greater the variety and the better the quality of the tools the more alert the user of them is likely to be. One should look up the new ideas in tools each year as one does in markets or crops. The advertising pages of rural journals are suggestive in this direction.

Hoeing the ground.

Plow drawn by men.

Plow drawn by oxen.

2242. Tools in the sculptures on a Theban tomb.

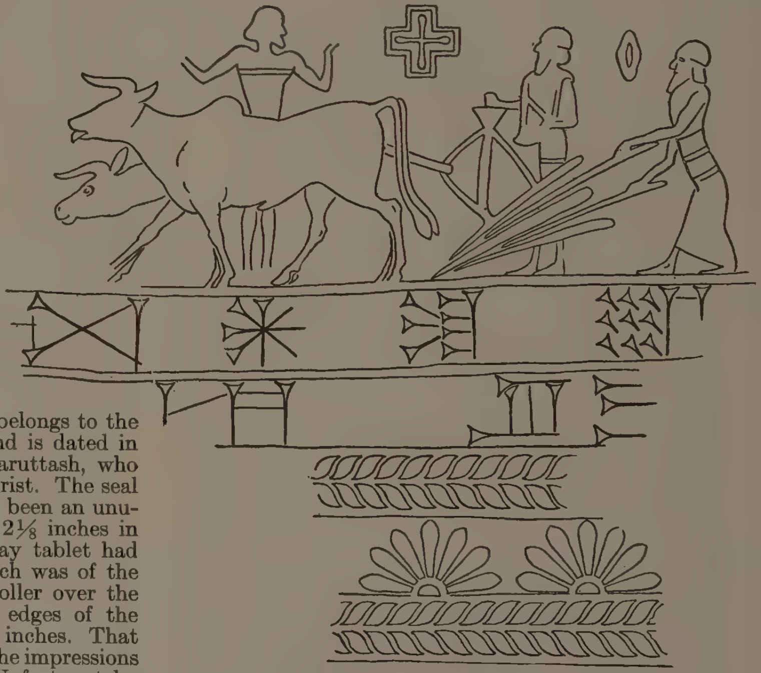
The very early tool for opening or tilling the ground appears to have been a forked or crotched stick, one prong of which was used as a handle and the other as a cleaving instrument. From this the hoe and the plow appear to have developed. (Fig. 2242.) This set of illustrations shows sculptures from a Theban tomb "of the eighteenth or the beginning of the nineteenth dynasty;" it is reproduced from Daubeny's "Lectures on Roman Husbandry," in which it is said that "The plough itself is nothing more than a modification of the hoe, which was first dragged along the ground by manual labor, before the force of oxen was substituted."

In "The Museum Journal," published by The University Museum of Philadelphia, June, 1910, Babylonian Section, is an interesting account by A. T. C., of "an ancient plow," together with an illustration (Fig. 2243). "An exceedingly interesting seal impression depicting a plow, drawn by two oxen, is found on a clay tablet with a cuneiform inscription in the University Museum. This tablet belongs to the Cassite period of Babylonian history, and is dated in the fourth year of the reign of Nazi-Maruttash, who lived in the fourteenth century before Christ. The seal used to make the impression must have been an unusually large one, for it measured about 2⅛ inches in length. After the surface of the soft clay tablet had been covered with writing this seal, which was of the usual cylindrical form, was run like a roller over the inscription on both sides and the four edges of the tablet, which measure about 2¾ by 4½ inches. That is, the entire document was covered with the impressions of different parts of this large seal. Unfortunately, there is no complete impression of the seal on the tablet. Some of the parts were repeated a number of times, but other parts seem to be entirely wanting. Moreover, the surface of a portion of the tablet has suffered considerably, due probably to the moisture in the earth, or exposure to the atmosphere after the tablet had been excavated. The accompanying drawing of the seal impression (Fig. 2243) was made after a careful study of the different traces found on the various parts of the tablet by Herman Faber, Miss Baker and the writer.

"The plow gang consists of three men. The one depicted larger in size than the others is doubtless the chief. He appears to be driving the animals, as is indicated by his raised arm, perhaps holding a whip. Another, having a bag over his shoulder, is in the act of feeding the tube or grain-drill, through which the seed was dropped into the furrow made by the plow, which is being guided by the third man. The animals drawing the plow, known as *alpu*, 'ox,' in the inscription, are in use in Babylonia at the present time. It is the Zebu or humped bull (*Bos indicus*).

"The individual for whom the seal was cut regarded himself as a devotee of Nin-Sar, the god of vegetation, as the first line of the inscription shows (Arad-NIN-SAR). Unfortunately the name of the owner in the second line is so imperfectly preserved that it cannot be read.

"For some time other representations of the plow in antiquity have been known, but in no instance is it so accurately represented as in this seal impression. A boundary stone of Meli-Shipak, of the Cassite period, recently found at Susa, contains the picture of a plow, which has hitherto been regarded as the earliest. It does not seem to have a tube. There is another picture of a plow found on an undated fragment belonging to the same period. Later representations of plows with tubes are found on monuments of Sennacherib and Esarhaddon. Plows similar to the one found in this seal impression are in use in Syria at the present time. The plow on the Museum tablet, here discussed, is the earliest known, being about a century earlier than the one on the boundary stone belonging to the reign of Meli-Shipak.



2243. Men plowing and sowing. From a Babylonian seal impression, 14th century B. C.

"It is also interesting to note that one of the latest inventions of our Western civilization whereby the grain is sown by machinery was already anticipated by ancient Babylonians at least thirty-three centuries ago. In fact the simple Babylonian device accomplished what no single piece of modern machinery does, in that it combined the processes of plowing and sowing."

A set of ancient plows is shown in Fig. 2244, reproduced from Bradley's "Survey of the Ancient Husbandry and Gardening," 1725. Bradley's explanation is as follows:

> "No. 1. Figure of an ancient Plough, supposed to be used about the Time of the *Romans*.
>
> "No. 2. Figure of a *Spanish* Plough, which some suppose, preserves somewhat of the Manner of the *Roman* Plough, only alter'd to be drawn by one Horse, instead of a Yoke of Oxen. 'Tis said, that the Husbandmen in *Spain*, will plough two or three Acres of light Land in a Day with this Plough.
>
> "No. 3. The common Shoulder Plough or best Plough, used in several Parts of *England*, for cutting or breaking the Surface of Grass Grounds, or Heath Lands; 'tis push'd along by one Man; sometimes cutting the Turf half an Inch thick, sometimes an Inch or two. At A is an Iron turn'd up with a sharp Edge, to cut the Turff from the rest of the green Sward.
>
> "No. 4. Is a Figure of the common Dray Plough, which is good to be used for miery Clays in Winter; but is not so proper to be used in Clays when they are hard.
>
> "No. 5. The Figure of a single Wheel'd Plough, used in *Sussex*.
>
> "No. 6. The Figure of the *Hertfordshire* Wheel Plough, which is of the easiest Draught; proper for any Grounds, except miery Clays, which are apt to clogg the Wheels. The several Parts of this Plough, being understood, will explain to us the Use of the other Ploughs. A is the plough Beam, B the Handle, Tail, Stilts, or Staves, C the Neck, or Share Beam, D the Earth Board, Mould Board, Furrow Board, Shield Board, E the Sheath, F the Share Iron, G the Coulter, H the Plough Pin and Collar Links, I the Plough Pillow, K the Wheels."

With these various forms may be compared those represented in Figs. 2245–2247; and also all the modern implements shown and described in the succeeding pages.

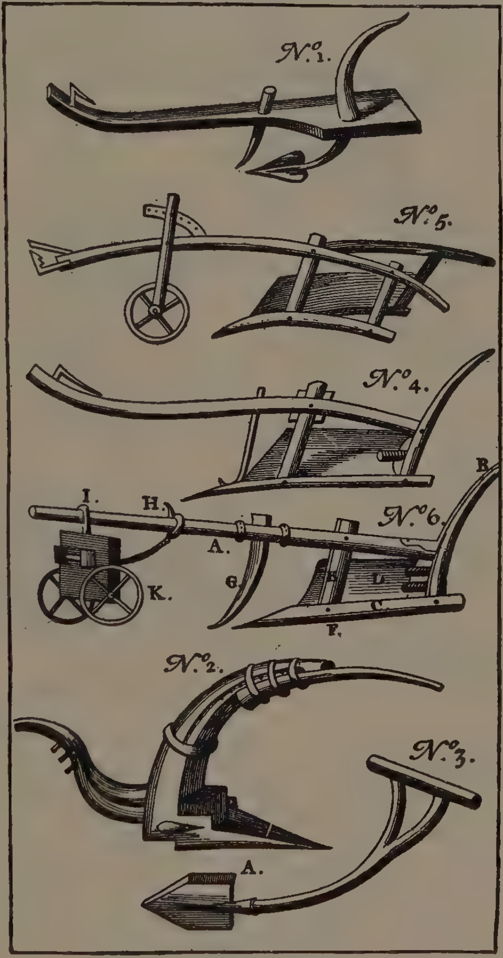
The hoe and the plow, and their many modifications, are still the fundamental or primary tillage tools, one being for hand-work essentially what the other is for power-work. As the necessity of tillage has come to be better understood, these tools have been greatly improved. It is surprising to know that the plow was not perfected until within a century. It is doubtful whether the invention of any of the most important machines of modern times has really meant so much for the welfare of the race as the development of this humble implement. To many persons is ascribed the credit of the invention of the modern moldboard plow, for the implement seems to have originated independently in different countries, and even in America there are various contestants for the honor. Thomas Jefferson, Charles Newbold, David Peacock, and others have been accorded the honor. There is reason for ascribing the modern type of plow to Jethro Wood, of Scipio in Cayuga County, New York. The years 1814 and 1819 are the dates of his most important patents, although the latter is usually regarded as the natal day of the implement. Wood was born in Massachusetts in 1774 and died in 1845 or 1846. (See "Jethro Wood, Inventor of the Modern Plow," by Frank Gilbert, Chicago, 1882.) The study of plows is a curious and profitable undertaking, and one that still needs to be prosecuted.

The large-area farming of North America and the apprehension of the principles that underlie tillage have resulted in the invention of a great number of surface-working tillage tools. These inventions are particularly important in orcharding, as they enable the grower to maintain the necessary surface mulch with small expenditure of labor and without training the trees too high. There are now many cultivators and harrows that cover a wide space and that are adapted to the light stirring of the surface soil without the turning of furrows and the ridging of the land. One who contemplates a serious study of tillage tools should familiarize himself with the inventions of Jethro Tull, before the middle of the eighteenth century. Tull devised implements to facilitate the tillage of plants when they were growing in the field. See Cyclopedia of American Agriculture, Vol. I, page 374.

In hand-tillage tools, the recent development of the wheel-hoe is significant for horticultural operations. This light and simple tool, usually with adjustable blades, performs the labor of many sets of fingers and does the work more effectively so far as tillage is concerned. It also enforces better initial preparation of the land in order that it may do its work more perfectly; and this remark will also apply to the modern seed-sowers.

There has been surprisingly little authoritative early writing on machinery and implements. Practically, our only sustained effort in that direction for many years was Thomas' "Farm Implements and Machinery," 1859 and 1869. Very recently, the subject has been taken up in the colleges of agriculture and elsewhere, and important reports and books are now available.

L. H. B.



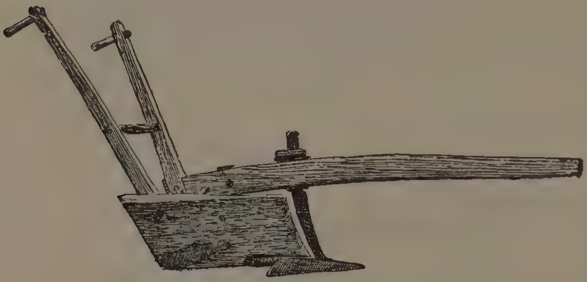
2244. Ancient plows.

The present symposium on machinery and implements in their horticultural relations comprises the following discussions:

- Tillage machinery (Trullinger), page 1942.
- Tools for the orchardist (Alderman), page 1949.
- Machines and implements in vegetable-gardening (Corbett), page 1953.
- Brief lists of implements for greenhouse and grounds (Thilow), page 1955.
- Spraying machinery and tools (Anthony), page 1956.

Tillage machinery.

Soil-tillage may be briefly defined as the art of preparing the land for the seeding and growth of a crop and of maintaining the necessary conditions until the crop has matured. The entire process of tillage for a certain crop consists of several more or less related but nevertheless distinct operations. The agricultural tools and machines which are especially adapted for the different tillage operations, and used in them are known as tillage machinery.

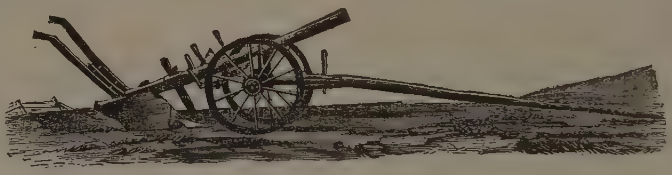


2245. An early Yankee plow, made of wood and the moldboard protected by iron nailed on. (After Roberts)

Purpose of tillage.

The different tillage operations form a chain, each link of which is necessary because it accomplishes one or more of the objects of tillage. The chief of these as stated in other works may be enumerated as follows:

1. To produce a deep, thorough, and uniform granulation, giving a well-marked crumb structure.
2. To regulate soil-ventilation, moisture-content, and temperature.
3. To destroy and prevent the growth of weeds and other undesirable vegetation.



2246. A former European type of plow, still used in improved forms.

4. To effect the deep and thorough incorporation of organic matter.
5. To make available the maximum amount of plant-food required by the particular crop.

In short, the object of tillage is to make the soil physically and chemically fit for crop-growth. Tillage is in itself a mechanical operation, producing at first only physical effects on the soil as shown above by the first four objects. The proper combination of these objects, however, results in the chemical transformation of certain soil compounds and the setting free of a certain amount of plant-food elements for direct assimilation by the crop. Proper tillage is, therefore, of the utmost importance in crop-growing, as it has to do with both the housing and nourishing of the crop.

Different tillage operations.

Tillage operations may be divided into two types or classes according to depth, as (1) plowing or breaking and (2) surface or comparatively shallow cultivation.

The first type of tillage may be applied to the breaking of virgin sod, the plowing under of stubble, or merely the plowing of land often plowed before. Plowing, however, may be considered as the basic operation of tillage. It is the first and most extensive step in the preparation of the soil for the crop and on its depth depends largely the extent of the physical and chemical perfection of the soil with reference to the crop. Furthermore, the success of the second type of tillage operations depends largely on the first type and, in fact, from the standpoint of economical and efficient soil management, the second type of operations is of relatively little use without being preceded by the first type. Although the second type of operations may be repeated a number of times until the proper depth of effective tillage is reached, it has been demonstrated in this country, and in Europe particularly, that such a method of procedure is usually impracticable.

Max Ringelmann, of the Institute Nationale Agronomique, Paris, distinguishes between the two types of tillage operations by calling the first type real-tillage and the second type pseudo-tillage. According to this classification, real-tillage consists in cutting, inverting and partially pulverizing the soil by plowing. The tough sod of the virgin prairie is turned over in a more or less compact slice and much of the dense poorly aërated texture remains. This necessitates the intensifying of the pseudo-tillage operations until the virgin soil is reduced to the well-aërated, loose, crumbly, and productive structure of the well-cultivated soil.

Stubble land is not only cut and inverted by real-tillage, but is usually pulverized to the desired texture much more extensively than is virgin land. Theoretically the pseudo-tillage need not, therefore, be quite so intense to produce the proper tilth, although in practice it can hardly be overdone. On land often plowed before, real-tillage, theoretically, should produce even greater pulverization than on the other two kinds of land. But, as a matter of fact, many such soils have been so repeatedly cultivated that they require progressively deeper plowing and intensive pseudo-cultivation in order to maintain the standard of good tilth.

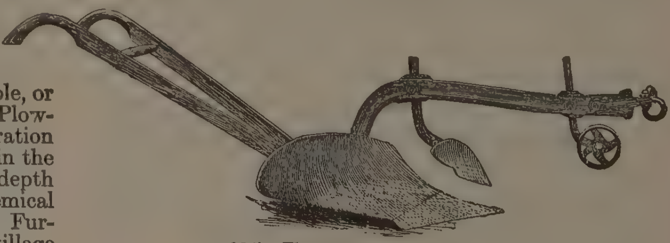
Pseudo-tillage consists mainly of the operations of harrowing, rolling, packing, clod-smashing, weeding, and stirring and pulverizing the surface soil generally. The pulverizing function is the main one in pseudo-tillage as it tends to improve ventilation and moisture-conservation. The rolling and packing function is perhaps next in importance and it is especially important in the drier localities from the standpoint of moisture-conservation.

In accordance with the above, then, the plow is the basic tillage tool and is the sole implement used in the first type of tillage, while the several forms of surface cultivators, including harrows, weeders, rollers, packers, cultivators, scarifiers, and pulverizers, constitute the list of machines used in pseudo-tillage.

The moldboard plow (Figs. 2245–2251).

The plow, without question, stands first among tillage implements. Historically it is probably one of the oldest of farm implements and from the standpoint of evolution its advance has been slow and its changes profound.

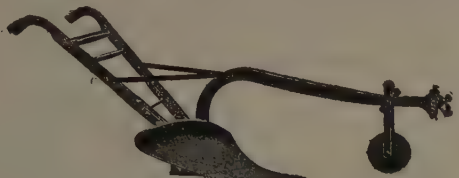
The evolution of the plow is here quoted from Davidson and Chase "Farm Machinery and Farm Motors," New York and Lon-



2247. The perfected American plow.

don, 1908: "The first plow was simply a form of hoe made from a crude stick of the proper shape to penetrate and loosen the soil as it was drawn along, ... The records of the ancient Egyptians illustrate such a plow.

"At an early time the point of the plow was shod with iron. Virgil describes a Roman plow as being made of two pieces of wood meeting at an acute angle and plated with iron. During the middle ages there was but little improvement over the crude Roman plow as described by Virgil. The first people to improve the Roman plow were the Dutch, who found that a more perfect plow was needed to do satisfactory work in their soil. The early Dutch plow seems to have most of the fundamental ideas of the modern plow in that it was made with a curved moldboard and was provided with a beam and two handles. The Dutch plow was imported into Yorkshire, England, as early as 1730 and served as a model for the early English plows.



2248. Moldboard view of a steel moldboard walking-plow showing beam wheel.

"Howard was one whose name may be mentioned among those instrumental in the development of the early English plow. . . . James Small, of Scotland, was another who did much toward the improvement of the plow. Small's plow was designed to turn the furrow smoothly and to operate with little draft. Robert Ransome, of Ipswich, England, in 1785 constructed a plow with the share of cast-iron. In 1803, Ransome succeeded in chilling his plows, making them very hard and durable. The plows of Howard and Ransome were provided with a bridle or clevis for regulating the width and depth of the furrow.

"Before the Revolutionary War, the plows used in America were much like the English and Scottish plows of that period. The plow used during the later Colonial period was made by the village carpenter and ironed by the village smith with strips of iron. The beam, standard, handles, and moldboard were made of wood and only the cutting edge and strips for the moldboard were made of iron. Among those in America who first gave thought to the improvement of the plow was Thomas Jefferson. Daniel Webster is another prominent American who, history relates, was interested in the development of the plow. He designed a very large and cumbersome plow for use upon his farm. It was over 12 feet long, turned a furrow 18 inches wide and 12 inches or more deep, and required several men and yokes of oxen to operate it. Charles Newbold, of Burlington, New Jersey, secured the first letters patent on a plow in 1797. Newbold's plow differed from others in that it was made almost entirely of iron. Jethro Wood gave the American plow its proper shape. The moldboard was given such a curvature as to turn the furrow evenly and to distribute the wear well.

2249. Bottom view of steel moldboard plow.

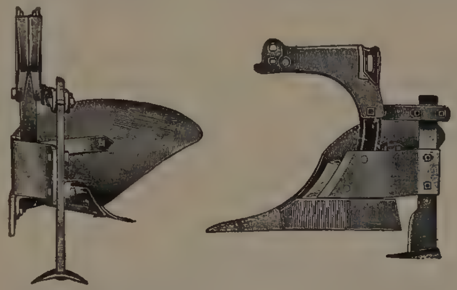
"As farming moved farther west the early settlers found a new problem in the tough sods of the prairie states. A special plow with a very long sloping moldboard was found to be necessary in order to reduce friction and to turn the sod over smoothly. Owing to the firmness of the sod it was found that curved rods might be substituted for the moldboard. Later, when the sod became reduced, it was found that the wooden and cast-iron plows used in the eastern portion of the country did not scour well. This difficulty led to the use of steel in the making of plows. Steel, having the property of taking an excellent polish, permitted the sticky soils to pass over a moldboard made of it where the other materials failed.

"In about 1833 John Lane made a plow from steel cut from an old saw. Three strips of steel were used for the moldboard and one for the share, all of which were fastened to a shin or frame of iron. John Lane secured in 1863 a patent on soft-center steel, which is used almost universally at the present time in the making of tillage tools. It was found that plates made of steel were brittle and warped badly during tempering. Welding a plate of soft iron to a plate of steel was tried and although the iron supported the steel well when hardened it warped very badly. The soft-center steel, which was formed by welding a heavy bar of iron between two bars of steel and rolling all down into plates, permitted the steel to be hardened without warping. It is very strong on account of the iron center which will not become brittle.

"In 1837 John Deere built a steel plow from an old saw which was much similar to Lane's first plow."

The modern steel moldboard plow is a three-sided wedge which is pulled through the soil by means of a beam and held steady by two handles behind. (Figs. 2248–2250.) The main parts of the plow may be enumerated as follows: (1) The share, or cutting edge, of which the point is the part first penetrating the soil. and the heel is the outside corner; (2) the moldboard, forming a twisted face which turns the furrow; (3) the landside, which receives the side pressure produced when the furrow is turned and aids in preventing the furrow from becoming crooked, particularly when irregularities in the texture of the soil are encountered; and (4) the frog, or metal shape to which the moldboard, landside and share are attached.

The functions of the plow with reference to the soil are a cutting function, an inverting function, and a pulverizing function. The cutting of the soil is effected in two planes, one vertical and the other horizontal. The inversion of the furrow-slice requires first a lifting and then a rolling of the slice to one side, bottom up. The pulverizing of the slice of soil is effected by bending the slice upon itself more or less abruptly and then dropping it suddenly upon the ground, the intensity of which effect is governed largely by the shape of the moldboard.

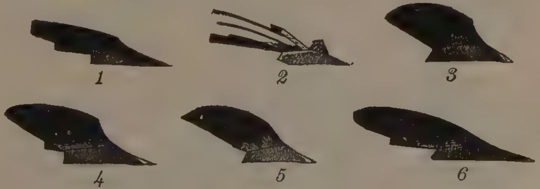


2250. Landside and back view of steel moldboard plow, showing subsoiling attachment.

In general, there are two extreme types of moldboard plow, namely, the breaker and stirring plow. Between these extremes occur several intermediate forms to meet all soil conditions. The average, or medium, of these is the so-called general-purpose plow.

The breaker (Fig. 2251) has a long low moldboard with no abrupt curvature which turns the slice of tough virgin sod gradually with minimum friction and effects little or no pulverization. This type of plow has been adopted for breaking tough prairie land owing to the advantage as regards draft over the other types. In some of the breaker plows the moldboard is replaced by rods bent to the shape of the moldboard, thus further reducing friction and consequently the draft.

The stirring or stubble plow has a short, high, and rather wide moldboard with an abrupt curvature, which turns the furrow-slice of old soil over suddenly and produces the maximum pulverization for a plow in that particular soil.



2251. Types of moldboard plows adapted to different kinds of plowing: *1*, prairie breaker bottom; *2*, rod breaker bottom; *3*, stubble bottom; *4*, general-purpose bottom; *5*, black land bottom; *9*, tame sod breaker bottom.

The general-purpose plow strikes an average between these two as regards shape and operation, and may be used either in stubble or light sod.

Deep plowing is objectionable in some soils, particularly in those having a sand or gravel subsoil, owing to the fact that it is inadvisable to bring this subsoil material too near the surface. Such soils may, however, be plowed deeply if the proper plow is used. Fig. 2252 illustrates a deep-tilling plow, which, it is asserted, is adapted for the deep pulverization of a soil, the subsurface soil of which should not be brought to the surface. It has a broad share and the moldboard is very narrow at the point where it joins the share but widens gradually at the upper end. The share loosens and pulverizes the bottom part of the furrow-slice which then falls through the space between the outer edge of the moldboard and the wing of the share, thus preventing its being brought to the surface. The broad part of the moldboard turns the upper part of the furrow-slice in the usual way.

2252. Deep-tilling plow equipped with jointer and coulter.

The material of the plow-beam may be either of wood or iron. While the iron beam is perhaps lighter and more wieldy than the wooden beam, it is likely to bend out of shape when the plow strikes a root or stump. The wooden beam will probably break under the same circumstances and can be replaced. The steel beam is curved over the moldboard and down to the landside. The wooden beam is fastened to the plow by a beam standard. The plow-handles are usually of wood and are fastened to the beam.

2253. Knife coulter fastened to plow beam.

A beam-wheel (Fig. 2248) is usually fastened to the plow beam, the function of which is to aid in regulating and maintaining the depth of plowing. Its proper adjustment is secured when it simply rolls on even ground without carrying weight.

The more common types of coulter (Figs. 2253, 2254) are the knife and rolling types. The coulter is used chiefly in sod-plowing but may be used in any soil. When the coulter is thick, dull, and improperly located on the beam it is likely to increase the draft. If, however, it is so located just behind the plow point as to cut directly above where the point and share are cutting and lifting the soil, the two parts of the plow should assist each other materially. When the ground is covered with wet corn-stalks, the rolling coulter should usually be set high and slightly back of the point. In very trashy ground it is often advantageous to set the rolling coulter well forward, but not on very hard ground. For stubble ground the rolling coulter had best be set about ⅝ inch outside of the landside and run one-third to one-half the depth of the furrow. For shallow plowing in sod, it may be set closer to the landside and should run the entire depth of the furrow.

2254. Rolling coulter.

The jointer (Fig. 2252) should be used when there is trash or organic matter on the surface which is not thoroughly covered. This implement is attached to the plow-beam in front of the plow and can be gaged to any required depth. As the trash is turned, it strikes the previous furrow a little below the top and is completely covered by the furrow-slice as it turns from the moldboard. In this way trash, and the like, is completely covered but not too deeply. Sod especially can be deep plowed when the jointer is used.

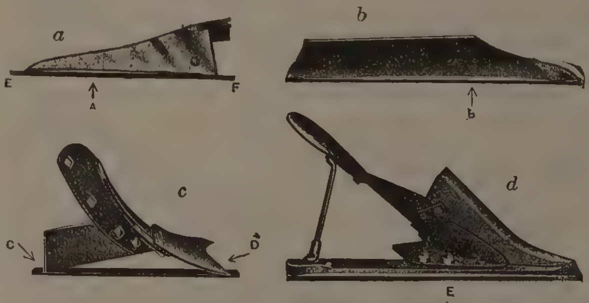
2255. Subsoil plow.

It is often necessary to use a subsoil plow when the soil conditions are such that deep plowing is out of the question. The modern subsoil plow (Fig. 2255) is built more or less on the principle of a coulter. It cuts a narrow gash in the soil, the depth of which is regulated by a beam-wheel, and the small point forms a sort of reservoir for water. The subsoil is thus aërated and the capillarity is generally improved.

In regard to the operation of walking-plows, it may be stated that a walking-plow is very sensitive to soil conditions, depth of plowing, the nature of the hitch, the set of the coulter or of the beam-wheel, and the set of the share. A walking-plow should usually be balanced about the point and run level. The proper set of the share point to secure penetration is shown in Fig. 2256*a*. There should be $\frac{3}{16}$ to ¼ inch of suction at point A. Hard plowing requires slightly more suction. Fig. 2256*b* shows the clearance in the throat of the share, which should be about ⅛ inch at point B.

Walking-plowshares have what is called a wing bearing. That is, a straight edge as shown in Fig. 2256*c* when placed at the rear of the landside point C and extending to the wing of the share point D should touch the share bottom from ¾ inch to 1¾ inches back of the edge, according to the size of the plow. The point of the share is also turned outward to the land to cause the plow to follow directly behind the team. As shown in Fig. 2256*d*, the clearance at E should be about ⅛ inch.

The plow must scour in order to operate satisfactorily; that is, the share and moldboard must be of hard material taking a smooth polish so that the furrow-slice

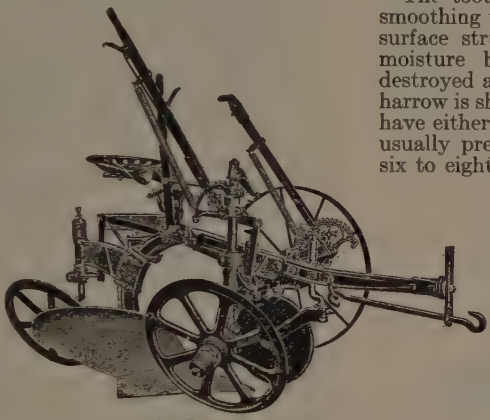


2256. Plow adjustments.

slips smoothly off without sticking. The plow must, therefore, be carefully polished and not allowed to rust. If the face is of good hard metal, hard soil-grains cannot scratch it. The plow must also be properly adjusted and the share and moldboard joined perfectly in order to insure perfect scouring.

2257. Frame riding-plow.

The riding-plow is more convenient than the walking-plow and generally does better work, particularly in dry soils. Two general types, the frame and frameless, are made. The frame plow (Fig. 2257) has its wheels attached to a frame which is connected to the plow-beam by "bails." This arrangement permits the lifting of the plow within the frame and the beam may be "floated" so that if the plow strikes a rock or other obstruction the plow only is raised and not the frame and the operator. The frameless plow (Fig. 2258) has no special framework and the wheels are attached directly to the beam by means of wheel brackets.



2258. Frameless riding-plow.

In the riding-plow, the side and downward pressure due to turning the furrow-slice is carried by the wheels and not as sliding friction, as in the walking-plow. It will be noted that the furrow-wheels are set at an angle better to carry the landside pressure. The rear furrow-wheel is usually turned a little from the unplowed land and in order to reduce the pressure on the landside is set toward the unplowed land 1 to 1½ inches beyond the landside. The front furrow-wheel is turned toward or from the unplowed land, according to the number and arrangement of the horses, and serves as a sort of side-draft equalizer. The plow is given the same suction as a walking-plow and the landside heel is raised about ½ inch from the furrow-bottom. The point is set the same as for a walking-plow.

2259. Riding gang-plow.

A sulky gang-plow is one having two or more plow-bottoms, so that two or more furrows may be plowed at one operation. Fig. 2259 illustrates a sulky gang-plow. A subsoiling attachment (Fig. 2250) is sometimes attached to one of the bottoms of a double gang-plow so that alternate furrows may be subsoiled.

The disc-plow (Fig. 2260) is the result of an attempt to reduce plowing draft due to sliding friction. In ordinary soils it has been found to have no material advantage over the moldboard-plow and the draft is in some cases greater. In sticky or very hard dry soils, however, it usually has the advantage over the moldboard-plow and operates with less draft.

The harrow.

The harrow is perhaps second in importance to the plow as a tillage implement. While the plow breaks the soil and pulverizes it in a general way, the harrow does finer work by breaking up clods and pulverizing the soil in detail. The original harrow was a tree limb with most of the branches extending on one side. Other early types were a forked limb with spikes driven in each arm and a rectangular-shaped frame having cross-bars each containing several teeth.

The main purposes of the harrow as a tillage tool may be enumerated as follows: (1) To effect pulverization and to secure a uniform soil-texture; (2) to destroy young weeds; (3) to improve soil-aëration; (4) to smooth the soil-surface; (5) to check evaporation; (6) to prepare a shallow seed-bed; (7) to cover seed; and (8) to mix manure with the surface soil.

Harrows may be grouped under perhaps three distinct types, according to the work they accomplish, as toothed- or smoothing harrows, disc-harrows, and curved-knife, clod-crusher, or pulverizer-harrows.

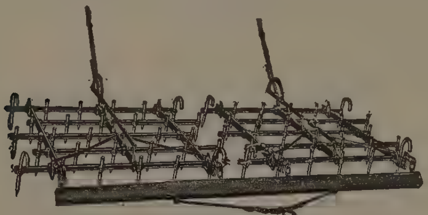
The toothed-harrow is effective in pulverizing and smoothing the surface soil of plowed ground. The fine surface structure produced tends to prevent loss of moisture by evaporation. Young weeds are also destroyed at a tender age. A common type of toothed-harrow is shown in Fig. 2261. The toothed-harrow may have either wood or steel tooth-bars, but the latter are usually preferable. The number of teeth varies from six to eight to a foot of width and these vary slightly in size for light and heavy soils. The lever enables the operator to incline the teeth forward for penetration and pulverization and backward for smoothing.

A steel harrow riding-cart is now used which may be attached so as to follow the harrow. Its wheels are made to caster to facilitate operations in turning. The harrow cart is a desirable adjunct to the harrow as it saves the hard labor of walking over plowed ground, and if properly constructed with wide-tired wheels does not cause an excessive increase in draft.

The disc-harrow is an implement of varied utility. It is especially adapted for rather deep surface-cultivation. One of its main uses is for preparing a seed-bed in plowed ground. It is likewise useful for preparing stubble or sod for plowing and for reducing sod after plowing. It is also useful as a general soil-pulverizer, for covering broadcasted seed in stubble, and for destroying weeds. In fact, many of our foremost agriculturists state that on an up-to-date farm the disc-harrow is indispensable.

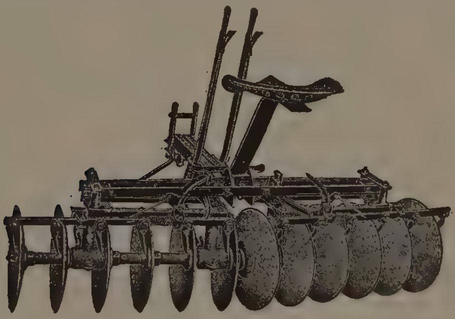
2260. Single disc-plow.

In Fig. 2262 is illustrated a common type of disc-harrow called the full-bladed type. The diameter of the discs usually varies from 12 to 20 inches and the harrow width usually covers from 4 to 10 feet. The depth of penetration of the discs is governed chiefly by the curvature and sharpness of the discs, the angle of the gangs, and the weight of the harrow.



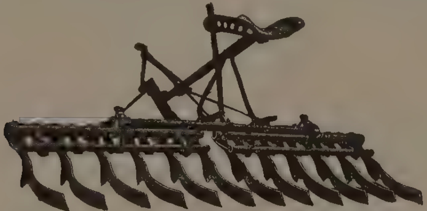
2261. Common type of toothed harrow with metal tooth bars.

The disc-harrow bearings are usually of wood, oil-soaked maple being preferred. The friction between wood and iron is less than between two pieces of iron, hence the value of wooden bearings. The end thrust of each gang is usually taken care of mainly by the bumpers between the gangs. The couplings between the main frame and the bearing-box casting are usually so arranged that the bumpers will come together with the angling levers in any position. The individual discs are usually set about 6 inches apart. The scraper for cleaning the discs may be made stationary or to be operated by the driver. A special type of disc-harrow for use in orchards has the disc-gangs widely separated so as to disc under trees without injuring the branches.



2262. Common type of disc-harrow, showing bearings and scraper.

The cutaway disc-harrow differs from the full-bladed type in that notches are cut out of the discs to permit deeper penetration. It has been found, however, that the pulverization is not so complete with this type as with the full-bladed disc-harrow. It has a further disadvantage in that the discs are difficult to sharpen since each disc must be removed and ground. Its principal use seems to be for renovating hay land and old pastures.



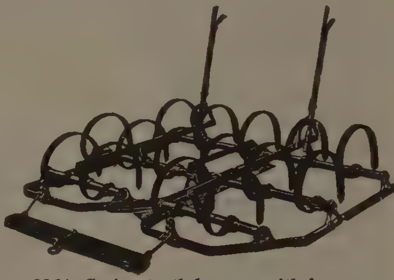
2263. Curved-knife harrow or clod-crusher.

A type of curved-knife harrow or pulverizer is illustrated in Fig. 2263. This is often called the Acme harrow. The slanting curved knives are effective in crushing clods, leveling the surface, destroying small weeds, and in producing the uniform soil structure so desirable for a seed-bed. Some of these implements have a set of rake-teeth following the knives, the purpose of which is to complete the pulverizing and smoothing process.

The so-called spring-toothed harrow illustrated in Figs. 2264, 2265, while in one sense a harrow, is really a cultivator. It is an implement which has been in more general use in Europe than in this country. The long spring teeth when striking a stone or root are easily released, thus making this implement effective in bad ground. It effects considerable pulverization but is said to have a rather excessive draft.

The weeder.

Weeds in a seed-bed or between crop-rows have been found to use up considerable moisture and plant-food. The plow and harrow serve to destroy many weeds, particularly the latter.



2264. Spring-tooth harrow, with frame.

Special weeder implements are, however, in use. These usually combine surface-cultivation with the destroying of weeds. One type used on seed-beds has a large number of rather long teeth with flattened and curved points which tear out and destroy weeds and pulverize or scarify the surface soil.

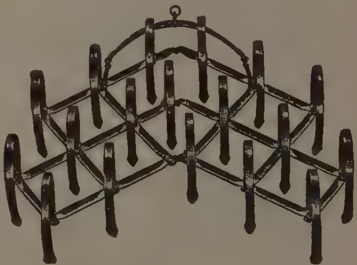
A second type, used between the rows of truck and root crops, is in reality a combination horse-drawn hoe, weeder, and cultivator. The hoes are broad and flat and by passing almost horizontally just beneath the surface of the soil, cut off and destroy weeds and at the same time form more or less of a surface mulch.

The roller, or packer and planker.

The roller as originally used was a tree-log. This, however, did not operate satisfactorily. Wrought- and cast-iron rollers succeeded the wood and they are now also made of concrete in some cases. Like the disc-harrow, rollers and packers usually have wooden bearings to reduce the friction.

While fairly deep general pulverization of the soil is desirable, the loose mellow seed-bed should be rather shallow and the plowed soil below be well packed to conserve moisture.

The iron roller (Fig. 2266) not only compacts the soil but effects considerable pulverization in the way of smashing clods. The smooth surface left by the roller, however, while desirable from the standpoint of mowers, binders, and so on, permits excessive surface evaporation and consequent loss of soil-moisture. This condition is remedied somewhat by following the roller immediately with a harrow, thus producing a surface mulch and breaking up evaporation.

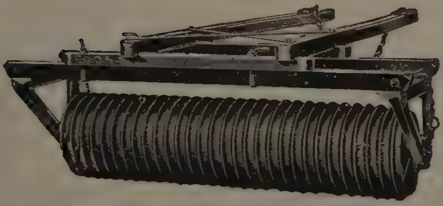


2265. Another form of spring-tooth harrow.

The roller pulverizer or pulverizer-packer (Fig. 2267) may perhaps be used to better advantage than the smooth roller. This type of roller compacts the subsurface soil and pulverizes the surface soil, leaving more or less of a mulch to prevent evaporation. Similar claims are made for corrugated and tubular rollers.

A so-called subsurface packer, consisting of a series of wheels with wedge-shaped tread, is on the market, for which many claims are made.

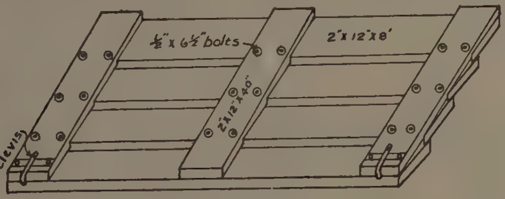
2266. Iron roller.



2267. One form of roller pulverizer or packer.

The Montana Experiment Station has been instructing the farmers of the state how to make their roller pulverizers of concrete. A circular has been issued describing and illustrating this method in detail. It is stated in this circular that the roller should weigh not less than 225 to 250 pounds to a foot of width. This is provided the roller is not used on moist soil. The concrete roller described is about 19 inches in diameter.

The planker (Fig. 2268) or clod-smasher is a home-made wooden implement which is very useful for crushing clods and for surface-smoothing. In fact, on some Hawaiian soils the wooden planker has been successful in pulverizing the top soil when both the disc- and Acme harrows have failed. The planker is effective in listed corn after the first plowing when the soil tends to be cloddy. The weight of the planker may be gaged according to the type of soil. The planker is more generally successful when the surface soil is rather dry. When the soil is wet and sticky, it may cause more harm than good by causing excessive packing of the soil. This also applies more or less to the roller.



2268. The planker.

Cultivators.

The term cultivator is applied to a number of tillage tools. These are surface tillage tools but are usually equipped with shovels or discs instead of teeth and some of them till the soil to a slightly greater depth than the harrow.

Cultivators are more generally used between the rows of growing crops, corn in particular. Corn-stubble is, however, frequently cultivated in the spring with a corn-cultivator previous to listing the corn. The main purpose of cultivators is to destroy weeds, pulverize and ventilate the soil, and thereby conserve moisture and plant-food.

The cultivator has developed from the single-shovel and double-shovel cultivator, which cultivated only one side of a row, to the single straddle-row and double straddle-row types. The single- and double-shovel types have also developed into cultivators having from five to fourteen shovels which are used for cultivating between two rows. These are used almost exclusively now for garden and truck crops. Fig. 2269 illustrates a common type of garden cultivator. These are made for both horse- and hand-power.

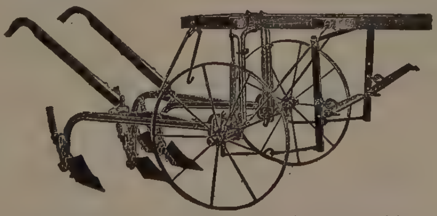
Corn-cultivators are of several types. There are single-row walking-cultivators with and without tongues, and single-row and double-row cultivators. The tongueless or "speechless" walking-cultivator is a rather old type and its use in the corn-belt now is rather limited. When standing still it was likely to fall in a heap if not held steady.

2269. Garden or truck cultivator.

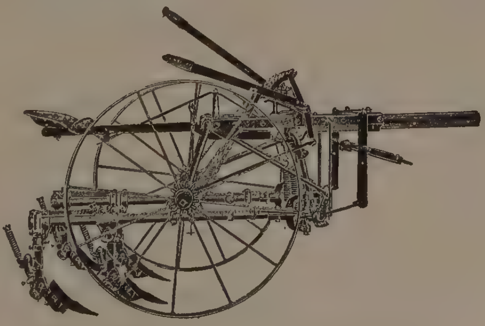
The single-row four-shovel walking-cultivator with a tongue (Fig. 2270) is a very effective corn-cultivator, particularly for second plowing. However, a strong man is required to operate a walking-cultivator, especially during second plowing when considerable care is required not to injure the corn and at the same time to effect thorough cultivation and destroy weeds.

Riding-cultivators are in very general use now for corn-cultivation. Fig. 2271 illustrates a common type of four-shovel single-row riding-cultivator. The shovel gangs are hung on springs and the shovels themselves are also sometimes fitted with springs better to withstand shock. The operator regulates the depth of the shovels by hand levers, maintains the required depth, and guides the gangs with his feet, the guiding being frequently aided by a hand lever.

Corn-cultivators now have four, six, eight, and sometimes ten shovels. While the four-shovel types do very good work, the six-shovel types effect a rather more

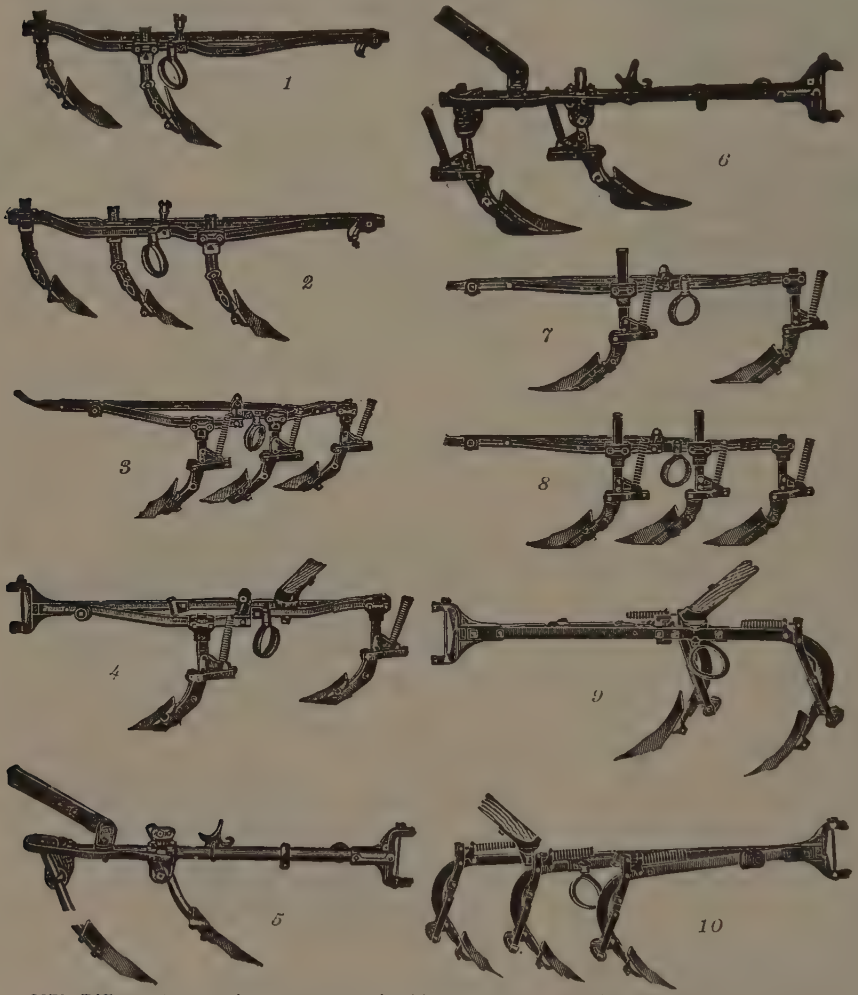


2270. Walking single-row four-shovel tongue cultivator.



2271. Riding single-row four-shovel cultivator.

intensive cultivation. In the opinion of many farmers in the corn-belt, increasing the number of shovels over six not only increases the draft but the difficulty in operating. The cultivator shovels are bolted directly to a shank. The shank is usually attached to the beam so that it may be raised or lowered. Where no provision is made for taking the shock caused by the shovel striking stones, roots, or stumps, the shank is hung by one bolt and fastened into place by means of a wooden peg. Thus when the shovel strikes an obstruction, the wooden peg breaks and allows the shovel and shank to turn back without breaking the beam. Fig. 2272 illustrates several arrangements of cultivator gangs.



2272. Different types and arrangements of cultivator gangs: *1*, steel beam, four-shovel; *2*, steel beam, six-shovel; *3*, steel beam, V-spring trip, six-shovel; *4*, steel beam, V-spring trip, four-shovel; *5*, pipe beam, four-shovel; *6*, pipe beam, spring trip, four-shovel; *7*, steel frame, V-spring trip, four-shovel; *8*, steel frame, V-spring trip, six-shovel; *9*, steel beam, universal spring trip, four-shovel; *10*, steel beam, universal spring trip, six-shovel.

Corn is usually cultivated three or four times. At the first cultivating the corn is usually very small and the operation consists mainly of killing weeds and stirring the soil. The shovels are usually turned so as to throw the soil away from the corn, and fenders are provided to protect the corn from clods and soil which are thrown toward it as the cultivator shovels tear through the soil. At the second plowing the shovels are not turned quite so much and it depends largely on the size of the corn whether the protecting fenders are used. But at the time of second plowing the weeds are usually thicker and the soil drier and harder so that the operation is usually a difficult one. The third plowing is often the "laying by" plowing. Corn is, however, often not laid by until the fourth and sometimes the fifth plowing. At this plowing the shovels are turned so as to throw the soil toward the corn, hilling it up around the roots. An objection made to the shovel-cultivator for laying by is that it cuts the corn roots. A surface cultivator is now used for this purpose which, it is claimed, does not cut the corn roots but throws the earth well toward the corn. Fig. 2273 illustrates a cultivator of this type.

Disc-cultivators are also used for cultivating corn and other row crops. The discs may be regulated to throw the earth toward, or away from, the corn. Fig. 2274 illustrates a cultivator of the disc type. Another type of single-row cultivator is the single-row "go-devil" which is equipped either with curved knives or discs and operates usually on wooden runners. This cultivator is often used for the first and second cultivation of listed corn. Fig. 2275 illustrates a "go-devil" of the disc type.

Two-row cultivators of both the disc and shovel types are now in use. It has been found that these implements require considerable practice for satisfactory operation. In addition, the rows must be straight and parallel and the weeds few. It is difficult to cultivate satisfactorily where irregularities in the rows are encountered. The draft also is practically double that of a single-row cultivator. On the other hand, it is contended that they do good work under proper conditions. The writer's experience with a two-row disc-cultivator in listed corn was satisfactory for the first plowing. Fig. 2276 illustrates a two-row combination disc- and shovel-cultivator. There are many such combination machines in use on single-row work, especially for listed corn. Fig. 2277 illustrates a two-row shovel-cultivator.

There are many other special types of cultivators adapted to different special kinds of work. Fig. 2278 illustrates a cultivator which is especially adapted to orchard cultivation. It is impossible here to cover all the types, but they all have practically the same purpose in view.

It is important that cultivators be well taken care of and that their operation and adjustment be studied so as best to adapt them to the requirements of a certain kind of cultivation. Cultivator shovels should be kept in good condition. They should scour the same as the moldboard-plow and should, therefore, not be permitted to become rusty. They are usually soft-centered with hard smooth face.

Conclusion.

It has been attempted in the above to describe only those tillage implements which have long been in common use on progressive farms and have undergone a steady development, and to illustrate examples of common types, not to recommend any of them.

The actual construction of the different types is touched on but briefly, but it is hoped that the discussion will be sufficient to give one at least a general idea as to the common types of tillage tools and their operation. As regards maintenance, it has long been known that tillage implements will not operate satisfactorily if not well taken care of. They should be protected from the weather and bearings should be well oiled both when in use and when not in use. Scouring surfaces should be protected from rust. And lastly, in the choice of tillage implements, considerable judgment should be exercised. Only strongly built machines should be selected. Bearings should be boxed to protect them from dust and dirt. Convenient and easy adjustment and operation may well be considered. It is also often true that a dollar spent on a good machine is worth several spent on a poor cheap one.

2273. Surface cultivator.

It is thought that a certain amount of study and investigation along the line of tillage machinery will be advantageous to any prospective farmer and may be a source of additional information to the old experienced farmer.

Robert W. Trullinger.

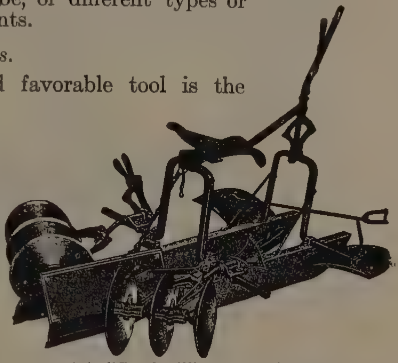
Tools for the orchardist.

Orchard tools may well be classified into three groups,—cultural, pruning, and harvesting implements. The first group comprises, with a few exceptions, the usual agricultural tools commonly used in a region for soil culture and probably require only a brief discussion. The implements used in pruning and in harvesting have been developed for a more specialized type of work and should be considered more in detail. No particular brand or make of tools will be recommended in this article but the writer will endeavor in some cases to point out the defects or the good points, as the case may be, of different types or classes of implements.

2274. Disc-cultivator.

Cultural implements.

An ancient and favorable tool is the plow, in the long development of which extended engineering skill has been expended. It might be supposed that in its development a highly specialized type would have been evolved for the rather exclusive use of the specialized industry of the fruit-grower. Such, however, is not the case. In the huge mountain orchards of the Appalachian range, one still finds the old shovel-plow used extensively and doing efficient service. Many of the orchards have been planted on newly cleared land and about the only implement which can successfully dodge stumps and tear up the root-bound soil is a strong oak-beamed narrow-pointed shovel-plow. For working the ground close to the tree, a long-beamed shovel-plow is used, so constructed that the plow sets off to one side, enabling both horse and driver to walk well away from the row. Between this crude tool and the heavy three- four- or six-bottom gangs hauled by a tractor, are all kinds of deep-tillage implements used in the orchard. The average fruit-grower with a moderate-sized orchard, carrying a good cover-crop to be worked up each spring, will still cling to the modern two-horse plow. In light soils a cover-crop may be satisfactorily incorporated into the soil with a disc-harrow or a light three-bottom gang-plow.

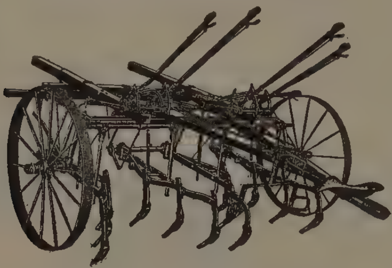


2275. "Go-devil" corn-cultivator.

2276. Double-row disc- and shovel-cultivator.

A tool well adapted for this work is the cutaway type of the disc-harrow. This machine will chop up and work into the soil a heavy cover-crop and put the surface into a fine tilth at the same time. In old sod orchards where the roots are so near the surface that plowing is difficult, the cutaway will often work up the surface into a sufficiently good condition to act as a mulch. It is not advisable to use less than an 18- or 20-inch disc, as the large size is a comfort when heavy work is to be done and the draft for light work is not appreciably greater than in the smaller sizes. For cultivating trees, the reversible extension type is to be preferred, as it enables one to throw earth either toward the trees or away from them.

The greatest advance in cultural implements for the orchard is found in the harrows, cultivators, and the like, used for shallow cultivation to maintain a dust mulch. The advent of low-headed trees brought about the extension harrow adapted for working under low-hung branches. Not only are extensions used, but in some cases they are covered with guards to lift the branches and prevent injury from contact with the working parts of the harrow. In maintaining the dust mulch, frequent but shallow tillage and a finely pulverized soil are essential. To meet these conditions, the harrow manufacturers have designed wide-cutting but light-draft tools, making it possible to work lightly a large area with a minimum amount of horse-power. Very many forms of teeth are used, some designed for pulverizing, others for leveling and others simply for stirring the surface.

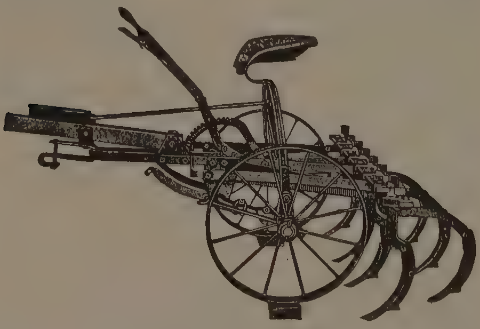


2277. Double-row shovel-cultivator.

The character of the orchard soil will determine, to a large extent, the type of shallow cultivator used. In soil free from stone or stumps and not uneven as to surface, the light tools, Acme or Kimball type, may be successfully operated, as may also the extra-wide (12 to 18 feet) spike-tooth and spring-tooth harrows. In rough or stony land, or among stumps, the orchardist must be content with the narrow but strongly built float or semi-float spike- or spring-tooth harrows.

The larger orchardists have recently developed an active interest in mechanical power for working the orchard. It seems true unquestionably that the tractor will eventually largely supersede the horse and mule in orchards of 100 acres and over. The cost of horse-labor and man-labor is constantly increasing and the cost of mechanical power is steadily becoming lower, so it seems to be only a matter of time when the latter will come into common usage. At present the tractor is of value only upon comparatively smooth land, free from boulders and stumps.

Some of the lighter tractors, when tested in West Virginia orchards, were unable to stand up under the strain. In other cases, the heavier types of tractors developed so much power that it was difficult to get cultural tools strong enough to stand the strain imposed upon them on rough or uneven lands. To strike a boulder or stump would usually mean the breakage of something. Both the "caterpillar" and the ordinary wheel-driven types give good satisfaction when conditions are favorable for their use, and the choice of design depends upon the local conditions.



2278. Orchard cultivator.

One interesting development of the mechanical power is found in the motor cultivator. This light and cheap outfit may be attached to almost any two-horse harrow or cultivator and will work efficiently in small orchards where the large tractor might prove unwieldy.

Pruning implements.

The implements used in pruning fall naturally into four classes: hand-shears and knives, long-handled shears, pole-pruners, and saws. No attempt will be made to consider different makes of these implements but the various types of each may be discussed with considerable freedom.

For a pruning-knife, the average orchardist will consider nothing but some sort of pocket- or clasp-knife. Those having rigid blades and handles are both inconvenient and dangerous to carry when not in use. In picking out a clasp-knife for pruning, one should choose either a slightly crooked (hawk bill), or a straight-edged blade. The hook in the blade causes the knife to "hang to the limb" when cutting toward the point and lessens the danger of slipping and cutting the wrong branch. The handle should be fairly thick and large enough to enable one to get a comfortable grip on it. The narrow metal handles sometimes seen are unmanageable and a forerunner of blisters and ill temper.

Great ingenuity has been displayed in designing hand-shears, but it seems that more thought has been expended in making an elaborate handle than upon the principles governing an effective cutting blade. Projections, loops and guards upon the handles are only a source of annoyance and hindrance. The simple, graceful, yet powerful handles of the American Rieser and California types are satisfactory and convenient in every respect. A poor spring in the handle will cause much trouble by slipping out or by being easily broken. Experience has demonstrated the superiority of the curved double brass spring over either the round or flat spiral springs. The fact that every catalogue of pruning-shears quotes prices upon extra spiral springs indicates their weakness.

The most important feature in a pruning-shear is the cutting part. The California pattern, which is probably more extensively used than any other, has a rather full rounded blade, well formed for cutting toward its base, but is a trifle too blunt at the point, a feature which sometimes causes it to slip off a limb when not securely gripped. The bluntness or roundness has a tendency to interfere with rapid pruning in young trees by making one open the jaws wider each time to receive the limb nearer the base of the blade. This difficulty has been overcome largely in the Swiss and American Rieser patterns in which the blade is made more tapering. These latter shears are somewhat finer pointed than the California pattern and can be used with greater ease to remove limbs from crowded crotches. With this exception, there is little to choose from between these two excellent types of shears. The French shears give good satisfaction, but have no advantages over the ones above mentioned. The straight-bladed types lack in cutting power and are poorly shaped for working in narrow crotches or where limbs are thickly crowded. The latter objection applies with equal force to the Connecticut and Henry patterns and the parrot-headed type, while one using the Lenin pattern will frequently find it almost impossible to prune closely where limbs are close together. The double-cut pruner has one objectionable feature in the fact that curved blades compel the wide openings of the handles to receive the limb. Anyone who has pruned will recognize how this will slow up the work and unduly tire the hand.

Long-handled shears are designed for lopping off heavier branches than can be cut with the hand-shears.

Much the same principles of blade-construction apply here as in the hand-shears, the thing to be considered being, first, ability readily to grasp the branches even though closely crowded, and secondly, power to make the cut. The draw-cut type is undoubtedly the most powerful and fairly well designed for grasping the limb. These shears are heavily built and the weight is sometimes objectionable. The double-cut type has blades so curved that it requires a wide opening of the handles to accommodate even a small limb. Of the other types, the tapering blade and Cartright patterns are the best, as they combine power and ease of operation through a high degree of efficiency.

Pole-pruners are designed for light pruning on such limbs as might be difficult to reach by hand-pruners and are specially adapted for rather small trees, such as peach, pear, cherry, plum and young apple trees. There are three types,—the pole-hook, pole-saw and pole-shear. Many of these are used in combination on the same tool. The blade in the pole-shear is often too light and is easily sprung out of shape in orchard work. The more elaborate shears and combination tools are usually somewhat cumbersome and unhandy in the orchard. The chisel-points used on some tools are of little if any value. For working in shrubs and brambles, it is difficult to find a more satisfactory tool than the bramble-hook.

2279. Types of step-ladders.

It seems to be a prevailing opinion regarding pruning-saws that the "Duplex" or double-edged saw should not be allowed in the commercial orchard. Even the most careful pruners will frequently gash the wrong limb with the back of the saw. The saw that comes nearest to filling all qualifications for pruning must be rather wide near the handle to give rigidity, and taper to a narrow point to allow close work between branches. The teeth should be of only moderate size but should have a wide set. Some prefer the swivel-saws but it requires practice to make a straight cut with them. The tapering swivel is of little use as the back makes it difficult to cut through a large limb. The California draw-cut type has many advocates and will cut rapidly, but it is adapted for small trees rather than general orchard use.

Harvesting implements.

Harvesting implements naturally group themselves under two classes,—those used in picking and those used in packing.

First among the picking implements comes the ladder. One of the early types of ladders consisted of a pole about 4 inches in diameter split at the base and spread apart, and provided with short cross-arms or pins at 12- or 14-inch intervals from the bottom to the top. This ladder, which is still used in some regions, is not well adapted for orchard service by reason of the side arms catching in the branches and interfering with ease in handling. Of the ordinary ladders, the type which is drawn together to a point at the top is far superior to all the others. The pointed apex is easy to insert into a tree and will rest securely and safely in the crotch of a small limb, when a wide ladder would press inward and split off the limb. The base of the ladder should be well sprung to give stability when resting against a tree. The maximum limit of length which is practicable to secure in ladders of this type is 26 or 28 feet and even these lengths are cumbersome and difficult to handle. A modification of the ordinary painters' extension ladder with a pointed apex is probably the most convenient to use in picking the tops of trees 30 feet or more in height. One should pick such a tree once for the experience and then make a vigorous application of the pruning-saw some feet below the top.

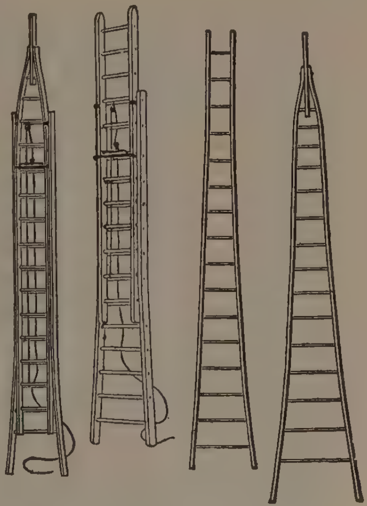
2280. Four-legged ladders, for use on level land.

For the picking of fruits from small trees, some type of step-ladder is used. The best kind for the commercial orchard is the tripod type in which the brace or support consists of a single leg. This will rest firmly upon uneven ground where it would be next to impossible to place a four-legged ladder securely. There are several forms of these ladders; those shown in Fig. 2279 are probably the most serviceable kinds. These ladders may be used as long as 10 or 12 feet, but 8 feet makes a more comfortable and practical length, particularly if the ground is slightly uneven. Some ladders are provided with an adjustable iron base for side-hill use or for service upon very uneven ground, which work fairly well but are rather heavy to carry, and the iron base sinks into the soil too much. Some peach-growers use a modification of the step-ladder in the form of a low platform on light legs. The four-legged ladders are shown in Fig. 2280; and forms of tree-ladders and extension-ladders in Fig. 2281.

The ladders described above are the ones mostly used by the experienced orchardist. For the orchard of the amateur and home grower, many elaborate or modified forms are offered, but while these are interesting they give way to simple pattern when the grower learns how.

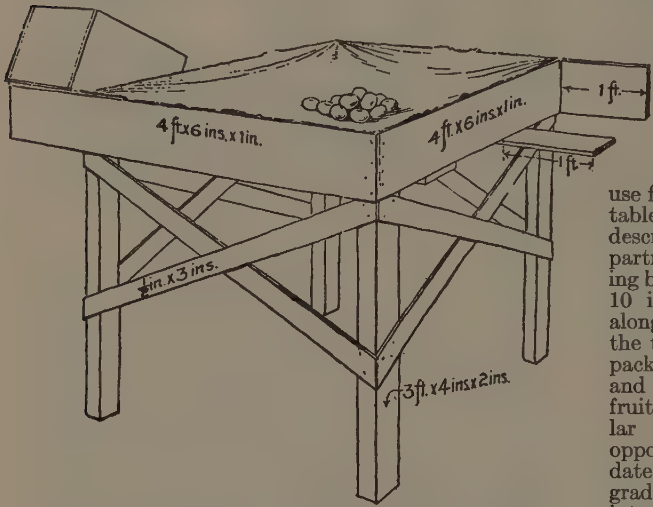
Another device that often appeals to the novice is the mechanical picker. Here many designs and styles may be offered, most of them consisting of a long pole with a cup at the end. The pole offers little opportunity for elaboration but in the form of cup, method of attachment, form of hook for dislodging fruit and other details, inventive genius has enjoyed an unrestricted field. Ingenious though these devices may be, their field of usefulness is extremely limited.

For picking apples, pears and peaches, the round, smooth-stave, swing-handle, half-bushel basket is probably the most



2281. Tree-ladders. At the left are two forms of extension-ladders

practical and widely used receptacle. The fruit will not bruise when placed in this, and the swinging handle enables one to let it down inside a barrel and empty the fruits without dropping them from a distance. Wire or rough-woven baskets cause unnecessary bruising because of their sharp and uneven surfaces. Many persons use a galvanized pail which discourages carelessness in dropping apples into the receptacle, as the noise can be heard for some distance.



2282. **A good packing-table for box fruit, with canvas bottom and racks at two diagonal corners for holding boxes.** (C. S. Wilson.)

Picking-bags are made in a variety of forms from the simple grain-bag hung over one shoulder on a strap attached at the top and bottom, to the carefully made apron-like pouch hung in front of the picker by straps over each shoulder. When used carefully, the fruit will not be badly bruised in the bags, but the average workman with a small sense of responsibility will bump the bag against the ladder and in descending will often let it rest from round to round to ease the weight upon his shoulder. It often happens in such cases that 90 per cent of the fruit is more or less bruised before it reaches the packing-tables.

In the packing of all kinds of fruit, very much depends upon the use of a good packing-table. If this table is not properly constructed, the speed and efficiency of the sorting-crew will be cut down and a poorly packed box or barrel will often result. The orchardists have realized this and are now using over practically the whole country the same type of table which by experience they have found superior to all others.

For the packing of apples or pears in barrels, the tilted, slat-bottomed table is almost universally used. The body of the table is from 3½ to 4 feet wide and from 6 to 10 feet in length. The sides and ends are of inch material 8 inches wide and the bottom is covered with slats 1 inch square running lengthwise of the table and spaced 1 inch apart. The legs are of 2 by 4 or slightly smaller material, 39 inches long at the lower end and 45 to 48 inches at the upper end. This allows sufficient height to place a barrel under the lower end and gives it enough pitch to keep the apples rolling down toward the lower end where the table is narrowed by a diagonal board to a funnel-like opening about 10 inches wide through which the fruit rolls to an apron over the top of the barrel. As the slack of the apron is filled, the packer lowers it carefully into the barrel, having meanwhile stopped the stream of apples by a gate, or with his hand.

The box-packers have practically standardized the type of table suited to their needs. The body is in the form of a square 4 feet on a side and covered by a canvas top which sags slightly and forms a receptacle to hold the fruit. The legs are 3 feet in length and should be of 2 by 4 material well braced. From opposite diagonal corners the sides and bottom pieces extend 12 inches to form a rest for the boxes. This table, illustrated in Fig. 2282, is often made much longer and the top divided into several compartments similar to the one described so that it would be adapted to use in a large packing-house. The fruit is first graded and each grade placed in a separate section so that the packer works with only one grade at a time.

The peach industry has not developed its type of packing-table to a form as standardized as has the apple industry. There is, however, a style of peach-packing table in rather general use for putting up the six-basket Georgia carrier. This table is somewhat like the long box packing-table described in the last paragraph, except that the compartments are 3 feet square and instead of the projecting box supports, a long shelf 10 inches wide is attached along the side 10 inches below the top. Upon this shelf the packers rest their carriers and reach over them for the fruit upon the table. A similar shelf is built on the opposite side to accommodate the baskets of the graders as they sort the fruit into several grades. Over the packing-table at a convenient height is usually suspended another shelf to hold extra dividers, baskets, and other materials.

2283. **Two simple screw barrel presses.**

Several types of box-presses are upon the market, but equally good ones may be built at home. The one illustrated in Fig. 2284 is a common type and is not difficult to construct. The iron clamps which may be easily made by a blacksmith are attached by pins and should be adjustable to accommodate boxes of different heights. Barrel-presses are of two kinds, lever and screw. They are equally good, the choice between the two being one of personal preference. The lever presses are a little more rapid and are also more tiring upon the operator. A narrow iron circle is preferable to the customary bar across the top, but this circle must not be large and unwieldy or it will interfere seriously with the operator's movements in placing the head. The simpler the construction of the press, the better. Two common types of screw presses are illustrated in Fig. 2283.

2284. **A press for box fruit. The clamps, worked by a foot-lever, press down the cover until it can be nailed.**

The mechanical grader is one of the most recent and probably the most significant developments in packing implements. The popularity of these machines is a clear indication of the spread of the movement for better packing throughout the country. It is impossible here to discuss the details of the various types of this machine (see *Packing*, Vol. V). In general they are so arranged that the fruit is carried over graduated holes, beginning with the smaller and ending with the largest sizes. In some cases these holes are in the form of a screen, in some a gradually widening groove or channel answers the purpose, while in still others ingeniously arranged spiral rollers or fingers force the fruit from one cup or hole to another until it is finally deposited in its proper receptacle. These machines are just emerging from the experimental stage and will doubtless be greatly improved in the near future, but it is worth noting that they are already giving good satisfaction. It is a safe prediction that in a few years they will be found in practically every up-to-date orchard of 10 acres or more in extent.

W. H. Alderman.

Machines and implements in vegetable-gardening.

The invention and perfection of tools specially adapted to particular uses and to the needs of different crops has had a profound influence on the extent of cultivation and the profits possible from vegetable-garden products. The character of the tool and implement equipment for market-garden and truck-farming purposes necessarily varies with the extent of the industry, the character of the soil, and the climatic conditions under which the work is conducted. The implements required by the gardener and truck-farmer may be grouped in the following way: First, soil-stirring implements such as those used in the preparation of the soil,—plows, harrows, levelers, clod-crushers, and so on.

Plows.—The ordinary moldboard plow is the best soil-stirring implement for use on restricted areas large enough to permit the use of horse-power. When the operations are of sufficient extent, the mounted plow which permits of working from one side of the land, instead of plowing around or back-furrowing, will be found to have decided advantages for garden use as it permits the preparation of a strip of land without making back-furrows or dead furrows.

Harrows.—To accomplish the various needs of soil-preparation, spring-tooth, spike-tooth, and disc-harrows should be available, and of the latter type there should be not only the ordinary disc- or cutaway-harrow but also several other types, some of which are shown in Figs. 2263–2265.

Levelers (Fig. 2268).—One of the most efficient levelers and clod-crushers is the planker, which can be made at home by placing three planks 10 or 12 inches wide so that the edge of one overlaps its neighbor 2 to 2½ inches and the three are firmly held together by bolting them to strong cross-pieces placed about one-fourth the length of the planks from either end. In irrigated sections, a different type of leveler is essential, but this need not be considered in the equipment for gardens located in humid areas. In gardens of good size a roller will also be found of decided advantage.

2285. A hand seed-sower.

The second class of soil-stirring implements comprises those used for crop-culture. Those that can not be dispensed with are the five-tooth cultivator, equipped with teeth differing in shape and size to meet the requirements of the various crops. The spike-tooth harrow (Fig. 2261), which has a similar frame but has numerous slender teeth in place of the blades of the one above mentioned, is another almost indispensable implement. Beside these horse-drawn implements, special tools, such as seed-drills for particular crops to be operated either by hand (Fig. 2285) or horse-power, will be needed. A battery of seed-drills is sometimes devised, for sowing several rows at a time. These are similar to fertilizer-distributers, which permit the operator to broadcast the fertilizer over the whole width of the row or to scatter it as a side-dressing near the base of the plants in adjacent rows. The implements needed for hilling, cultivating, or digging particular crops are to be determined by the character and extent of the crops grown.

Hand implements for cultural purposes.—Implements for hand work are quite as essential as the more expensive and more effective horse-drawn inventions and no garden can be successfully cultivated without a variety of hand-hoes, such as broad, pointed, and scuffle-hoes as well as an equipment of wheel-hoes with adequate attachments for performing the various operations necessary to the successful culture of small garden plants. Besides these, hand-weeders, dibbles, and trowels cannot be dispensed with.

2286. The hand wheel-hoe.

Among the special soil-stirring implements worthy of consideration are the following:

The Meeker disc-harrow.—The successful germination of small seeds depends more upon the preparation of the soil than any other single factor. The market-gardener has a number of small-seeded plants to handle and the quick and adequate preparation of the soil is an important matter. Before the Meeker disc-harrow came into use, the work of preparing a seed-bed for small seeds had to be done by hand. By the use of this implement, the final preparation of the seed-bed can be accomplished by the use of horse-power in as satisfactory a manner, in much less time and at less cost, as it can be done by hand. This implement fines, levels, and compacts the surface soil. In fact, it does the work of the steel-tooth garden-rake in an extensive way.

The wheel-hoe, shown in Fig. 2286, of which there are many modifications, has played an important part in the evolution of modern truck- and market-garden industries. In the hands of a skilled operator, it can be made to perform a major portion of the operations possible with the hand-hoe or broad hoe and the amount of execution possible is multiplied many fold.

The scuffle-hoe, which is a very slight modification of the ordinary hand-hoe or broad hoe, as shown in Fig. 2287, has not only minimized the effort needed to accomplish certain results but has at the same time placed at the disposal of the skilful operator a more effective implement. The combination of these two factors, conservation of effort and increased efficiency, should mean lessened cost in the operation to which the tool is adapted.

Next to the soil-stirring implements, those which distribute the seed either in drills or hills, as the special crop may require, and those which distribute fertilizers to stimulate the growth of such crops, bear a very intimate relation to the success of any horticultural enterprise.

The perfection of reliable row- and hill-dropping drills for sowing extensive garden areas has greatly reduced the cost of producing many crops. The combination of seed-sowers by the use of special carriages, which are used in sowing spinach and kale on four- or five-row beds, or for planting large areas of hoe-crops such as beets, carrots, onions, radishes, or even cabbage, has greatly augmented the uses of the seed-sower and reduced the cost of seed-sowing.

The adaptation of fertilizer-distributing devices to the seed-drill still further reduces the labor-cost involved in the production of those crops requiring or permitting the distribution of fertilizers with the seed. Such inventions make it possible to substitute brute-force for man-power to a marked degree, thus increasing the efficiency and productive capacity of the man.

Another but somewhat more complicated device which lends itself in a number of labor-saving ways to the work of the market-gardener and truck-farmer, is the McWhorter fertilizer-distributer. This device is built for hand- and horse-power. It is so adaptable as to be readily adjusted for sowing fertilizers broadcast, or in drills, or as side-dressing to plants in rows. Truck-growers have long ago learned that in order to secure best results, fertilizers should be applied at particular periods in the life of the plant as well as in definite quantities in a special way. This implement meets these several needs more completely than any other fertilizer-distributer yet devised.

One of the minor implements worthy of mention in this connection is the celery-hiller. In those sections in which autumn celery is extensively produced for storage, the crop is partially blanched before it is stored. Until recently this blanching was chiefly accomplished by banking the plants with earth. When done by hand, this is a long, tedious and labor-consuming task, but with the aid of the celery-hiller operated by horse-power, human effort has been largely replaced and the cost of the operation has been correspondingly reduced. The onion-topper is another device which, like the celery-hiller, has reduced the amount of irksome and expensive labor in handling a crop.

2287. Various forms of hand-hoes. The common square or broad hoe runs through the cut. Above it is a weeder and one form of scuffle-hoe. Below at left is a common kind of scuffle-hoe; and below it is a hand-cultivator. Other special hoes are shown.

It often happens that a recombination of elements results in a device of special merit in accomplishing important results. A combination of seed-drills is an achievement of this character which has solved an important problem in connection with the planting of spinach on raised beds. The climatic conditions, the texture of the soil, and the drainage requirements of the spinach plant have made it necessary that the crop be grown on four- to six-row raised beds. After these have been prepared, the tramping of operators to sow the seed with ordinary hand seed-drills would be objectionable, the work would be difficult and expensive. The battery of drills operated by horse-power has solved the problem for spinach as well as for planting sugar-beets and the sowing of onion seed for sets. In fact, in some cases a tractor has supplanted the battery of seed-drills.

Some of the implements that have had an epoch-marking influence on the crops, the special problems of which they were designed to meet are:

Transplanter.—The degree of perfection which has been attained in the modern transplanting devices has practically taken all the "backache" out of the extensive culture of all transplanted crops which are grown far enough apart to permit the use of a slow team to propel the planter. Such crops as cabbage, cauliflower, sweet potatoes, tobacco, and strawberries lend themselves to planting by this type of implement. Such crops as onions and celery, which are also transplanted, cannot be successfully handled with the models now on the market. The reason for this is due to the close planting distances required by such crops. It is not the proximity of the rows but the distance between the plants in the row that prevents the success of the machines now available. Preliminary tests that have been conducted with motor-driven implements of this character indicate that the solution of the problem lies in this field, for motor-driven devices can be geared to travel at any desired speed, but draft animals, while sometimes exasperatingly slow, cannot be trained to go slow enough to permit operators to set plants as close as 4 to 6 inches apart in the row.

The potato-planter.—The invention and perfection of this device has removed the operation of potato-planting from the domain of crew labor when potatoes are grown on an extensive acreage, to the domain of extraordinary extensive field-planting operations. It has reduced the man-labor requirements at potato-planting season so that a very slight increase in labor is capable of accomplishing what on a hand basis would be almost impossible in many sections where potato-growing now thrives. There are two general types of potato-planters which, for convenience, may be designated the "one-man" and the "two-man" types. Each of these machines has special advantages. The one-man type is less expensive to operate than the two-man type, but since the operator must depend upon the precision of a mechanical device unaided by personal supervision to secure the distribution of the seed, and since vacancies in the field tend rapidly to reduce the yield of the crop without reducing the cost of cultivation, the grower should consider carefully whether or not saving the labor of an extra man at planting-time is really a gain or a loss at harvest-time. The one-man type of machine, which uses pickers that puncture the seed-pieces, is liable to be an important factor in spreading certain types of tuber diseases. If such machines are employed, extreme caution should be exercised to eliminate from the seed-stock all tubers carrying diseases capable of communication from seed-piece to seed-piece by means of the metal pickers. The two-man machine costs more to operate, as it requires two instead of one man. If the seed has been carefully cut and the feeder attends to his job, this machine should give a perfect distribution and a corresponding stand. These devices are provided with another time- and labor-saving feature in the form of a fertilizer-distributing device. These attachments are so arranged as to place the fertilizer in the row, either deeper than the seed-piece or to scatter it into the drill in which the seed-piece is dropped.

The potato-digger.—Of the special implements designed to increase the efficiency of horse- and man-power expended in handling the potato crop, none has proved more of a boon to the grower than the potato-digger. It has made it possible to accomplish by means of horse-power in a given time what it would take several men to perform; to harvest large acreages at low cost in an incredibly short time; factors of great economic advantage considered from the point of cost as well as from that of safely gathering and storing the crop. It often happens in the northern potato-growing areas that the interval between the first killing frost, which is the signal for all hands to begin digging, and the time when actual freezing temperatures occur, is very short. It is therefore imperative that the facilities for digging and storing the crop be capable of accomplishing large tasks in short periods of time. The large, strongly built diggers upon which six horses are sometime used are implements of this type.

The pea-viner.—The invention of the pea-viner promoted the culture of garden peas from a minor place in the market-garden and on the truck-farm to the position of an acreage crop to be harvested with machinery and carried to the cannery. It made pea-canning a factory enterprise instead of a side line to market-gardening and truck-farming.

Implements and devices which assist the grower in the production or preparation of his crop for market are of great economic importance, although often simple in design and relatively inexpensive. Such tools are well illustrated by the better types of hand-weeders, dibbles, and transplanting trowels. The asparagus-buncher, is a simple and inexpensive device which enables the asparagus-grower to accomplish two important ends—offering his product in uniform standard-sized bunches and of such length as the trade demands. Some markets and special trades require stalks of extra length. By the use of the buncher, a standard once established can be uniformly maintained.

While this by no means exhausts the list of special implements used in the production and preparation of vegetable crops for the market, it serves to point out the place which some of these implements and tools hold in the commercial production of these crops, as well as suggesting in a general way the fundamental equipment of a place devoted to the production of vegetable crops.

L. C. Corbett.

Brief lists of implements for greenhouse and grounds.

The purpose in using tools for working the soil, either in the greenhouse, garden, lawn or on the farm, is to secure efficiency and also to save time and labor. Soil-working tools for greenhouse use are few and very practical. In many cases, the operator requires specially constructed tools for the work. The necessity for tools is also modified by the way in which the plants are grown and trained. In an article of this kind, the principles of operation of the endless list of greenhouse and lawn tools cannot be discussed; but a list can be suggested of the kinds of mechanical helps that the gardener most needs.

Many simple methods have been introduced to eliminate crowding and irregular growing in commercial and also in private houses, where bench-growing is conducted to any extent. There have come into use, within recent years, wires stretched horizontally over beds of roses and carnations, to which the vertical wires are fastened by clips. The method is good, as it looks neat and prevents irregular growth of the plants and admits use of proper tools for cultivating. For this tillage, the Eureka weeder, with short and long handles, is about the best, being made of flexible steel with narrow teeth, thus preventing seriously disturbing the roots when used for cultivating and weeding. The method of running the horizontal wires from end to end of the staging is by fastening them to a cross-bar of ¾-inch-diameter galvanized pipe, so constructed and braced as to form an anchor at the elevation that accommodates the height of the plants. Wire pot-hangers are convenient for overcrowded spaces; also for such plants that do best by being suspended and given abundant light and air. These supports may themselves be classed with greenhouse devices and implements, and they determine to a considerable extent the character of the hand tools that may be used on the bed or bench.

The watering-can is perhaps the most important requisite in the greenhouse or conservatory, but for the commercial house the hose is used entirely for watering and spraying. The long-spout can, fitted with brass tubing for attaching the rose or sprinkler, is the best. The special low can of four-quart size is used for watering seed-pans and boxes which are often placed at an elevation above the benches. The number of forms of watering-pots now available is considerable and represents excellent adaptation of means to ends.

Fumigators are necessary devices against insects. The combined fumigator and vaporizer acts in a double capacity, generates tobacco vapor as well as smoke, and prevents burning, which is often caused by the dry smoke. The fumigating lamp is used for vaporizing nicotine extract. Any apparatus of a lamp type will accomplish this work successfully. The brass syringe with its varied-sized caps, coarse and fine, for spraying or syringing and sold for watering seed-pans and boxes, is still in general use. Pressure sprayers are a greater convenience than the syringes and much more efficient for applying insecticides.

Among many important requisites for the greenhouse, the thermometer is an indespensable factor, as are also flower-pots, fern-pans, orchid-pans, orchid-baskets, seed-pans, and flats of wood used for seed-sowing and also transplanting seedlings, soil-sifting sieves for hand use, specially constructed wheel-barrows for greenhouse use, pot-washing machinery from the old style scrubbing-brush to the revolving brush machine of greater power and capacity which is used by the commercial florists.

In large commercial establishments, particularly for vegetable-growing, where the bench and staging are no longer used, the soil is handled the same as in the open, with either the spade-fork or plow, but in houses with side benches and large center staging, the soil is removed and replaced by hand carrying-boxes operated by two men, and in modern and extensive establishments by tilting cars running on a continuous cable. The very coarse soil is broken up and sifted through large riddles, 6 feet long and 3 feet wide and standing on an angle.

Tools for the lawn.

The finished lawn requires constant attention. It does not demand a great variety of tools, but they should be practical and efficient. Of the lawn-mowers, the most recent is the gasolene motor, which has the great advantage of doing the work of mowing and rolling in early spring without disfiguring the lawn, as is the case when using the horse lawn-mower. Steam- and gasolene-power lawn-mowers have been in use for several years, and have hitherto been very heavy and unwieldy; however, in the recently introduced machines, the weight is no greater than the horse-power 30- and 36-inch-cut mowers. The operator usually walks in the rear where he has full control in guiding the machine and regulating the power. In large park areas, private or public, the ordinary farm mowing-machine may be used; and in some places sheep may be employed to crop the grass, as on golf-courses. The old-fashioned grass scythe still has many uses about large lawns.

The lawn-sweeper for hand- and horse-power is a lawn accessory not in general use, but it does finished work, particularly in late summer and fall, when the fall and other coarse grasses make their appearance, and prevents their seeding for the following year's crop.

Hand lawn-mowers of low- and high-wheel makes are now used in all parts of the world where lawns are to be found. Without the hand lawn-mower, the tennis-court and the putting-greens of the golf-links could not be kept in proper condition for use. The cropping of grass for appearance serves two purposes: it induces thick growth and insures an even surface.

The lawn-roller is the first lawn tool used with advent of spring. It closes the surface of the lawn which has been honeycombed by the frosts and freezing during the winter months, firms the soil and grass roots into close proximity, and also presses down the mole-runs. After sowing grass seed, whether in the already established lawn or in a new one, the rolling process is essential. Every horse- or other lawn-mower is equipped with a roller and can be used as a roller only.

Dock-extractors, dandelion-lifters, steel spuds and knives for cutting plantain are all used for exterminating objectionable weeds, which infest lawns. Scythes and grass-hooks (sickles) are the grass-cutting tools to be used where the lawn-mower cannot be employed. Grass-shears and border-shears are essential for cutting grass along the edges of foot-paths, walks, flower-beds, and also along the edge of carriage-roads. Lawn-shears are used for cutting grass under fences and under trees that grow close to the ground. Grass-edging knives and narrow spades are also used for cutting along borders and beds in the spring to secure an even edge.

2288. Various commendable forms of lawn and garden rakes, forks and hoes.

The leaf- and rubbish-cart, the leaf-rack of wire placed on a broad-tired wheelbarrow, make excellent vehicles of man-power to transport all kinds of rubbish, tree branches and leaves from the lawn to the deposit for such. Lawn-rakes for leaves, scarifying rakes for reseeding and removing moss surfaces in shaded portions of lawns are useful. Lawn-sprinklers are obtainable for the small grass-plot, and for large areas of almost indescribable patterns and capacity, stationary and revolving.

For even distribution of fertilizers and grass seeds, the use of the "velvet lawn seeder and fertilizer sower" is recommended. These machines are so constructed that they cut shallow grooves in the sod, sowing the seed directly into the openings to insure germination, also covering and rolling in the same operation. The fertilizer machine is arranged with a comb similar to a rake, thus scarifying the lawn before the distribution of dry fertilizer, as bone, sheep-manure, nitrate of soda, ashes, ground lime or plaster.

Tools for the garden.

Garden tools are in endless variety and there are special types for either light or heavy soils. The spade is still the best tool for the heavy soils, and the digging-fork for light soils; the hoe persists for all soils. The scuffle-hoe is standard for cultivating and weed-cutting; the Warren hoe for cultivating, furrowing and ridging; the common garden hoe in one, two and three prongs for cutting weeds and breaking the soil; the square and half-moon hoe are used principally for cutting weeds and leveling the surface (Fig. 2287). Steel garden rakes, narrow and wide (Fig. 2288), are necessary for leveling broken soil. Steel-bow rakes are useful for handling coarse cloddy soil.

Wheel-hoes, and cultivators with adjustable teeth for cultivating, discs for breaking clods, plows for ridging and furrowing, and also for opening the earth for planting and sowing, are the most practical garden tools, being great labor-savers. When properly and frequently used, they will keep a garden neat and clean. Seed-drills are not practicable for a small garden, but for the market-garden they are most important, both for uniformity and economy in sowing the seed, obviating thinning by hand. The hand-thinning is an expensive operation, wasting the plants that are pulled out, and injuring what are left. The modern seed-drill is so constructed that it will drop seed at intervals as well as distribute them in a continuous line. This form is known as the hill-dropping drill. Some drills are equipped with interchangeable cultivating tools. The market-gardener does not consider this feature practicable, and therefore prefers separate drills and cultivators; but for hotel and private gardens the combined tool is used.

All vegetable seeds, except lima beans, can be sown with seed-drills; they open the furrow, sow the seed, cover, press it down and make the mark for the next row to be sown, all in one operation. The first row being marked out with garden-line, the marking-iron is set at the required distance. The double wheel-hoe and cultivator is the market-gardener's favorite, as it can straddle the row and cut from each side, thus throwing to center of row. The operator then rakes out the center, following between the rows with teeth attached to the hoe to break the soil. The hand-plow is a favorite tool for the private garden. It can be set at different depths.

The wheelbarrow-drill in 14- and 16-foot lengths is the most uniform distributer of grass seeds. Over large areas, it is arranged with an agitator inside to force the seed through the openings. The lawn-seeder is equipped with discs which cut shallow openings into which the seed drops. Fertilizer-drills are used, as already indicated, for the field, garden and lawn, and distribute evenly and in the required quantity.

J. Otto Thilow.

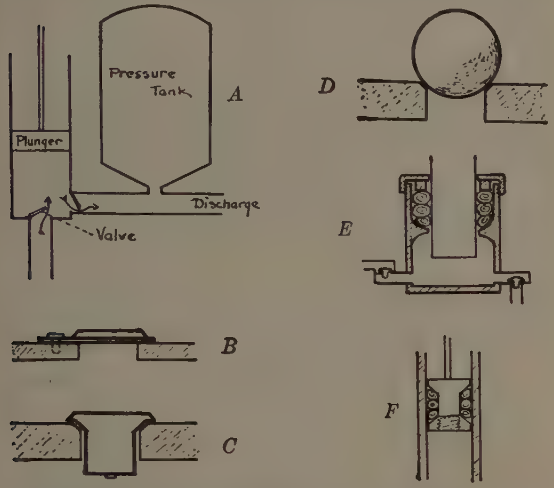
Spraying machinery and tools (see also pp. 1057–1060).

In recent years, the appliances and devices for the application of sprays to destroy insects and fungi have become numerous and much specialized. As the pests to be met are many and very different, so is the machinery of the most diverse patterns. Certain standard practices, however, have developed a line of implements that meets perhaps four-fifths of the needs, and some of these constructions may be briefly considered here. Spraying is now one of the established practices in the growing of plants.

Pumps.

The spray-pump is the ordinary lift-pump found in most wells to which has been added a means of regulating the discharge, thus changing the lift-pump to a force-pump. If a tight-fitting plunger moves up in a cylinder, it pushes in front of it a certain amount of air and an equal amount rushes in behind the plunger to fill the space. If the lower end of the cylinder is placed in water, as the plunger moves upward air is still driven out at the top but, since none can now enter at the bottom, there is a tendency to create a vacuum and the atmospheric pressure outside the cylinder forces the water up toward the plunger.

One may swing a door open in one direction but it closes tightly against the jamb in the other direction. If a similar arrangement, called a valve, is put at the bottom of the cylinder, water can then enter but can not run back and the water which enters the cylinder is thus held. If a discharge-pipe is now placed at the lower end of the cylinder, as shown in Fig. 2289, *A*, and a valve placed in this which swings so that water can flow out, but not into the cylinder, our simple pump will be completed. On the upward stroke of the plunger one valve opens and the other closes; on the downward stroke this action is reversed and the water is driven out the discharge-pipe.



2289. ***A*, diagram of a simple pump; *B*, the clapper valve; *C*, the poppet valve; *D*, the ball valve; *E*, an outside-packed pump; *F*, an inside-packed pump.**

The water from such a pump would come in spurts with each stroke of the plunger. If an opening is made in the bottom of an air-tight chamber, or tank, and this connected with the discharge-pipe, we have a means of preventing these spurts and maintaining a steady pressure at the discharge. When the piston moves downward and water is sent into the discharge-pipe, some of it is forced up into this air-chamber, compressing the air as it enters. When the plunger starts backward, this compressed air can then expand and force out the water. Thus, part of the time, water is leaving the discharge directly from the push of the plunger and part of the time from the expansion of the air in the pressure-tank.

There are three general types of valves: (1) *The clapper valve* consists of a flat plate covering the valve opening and hinged on one edge so as to swing in the manner of a door (Fig. 2289, *B*). Frequently the face of the plate is covered with rubber or leather. Except in a few of the cheaper hand-pumps, this valve is not found in modern spray-pumps. (2) *The poppet valve* is one of the most widely used forms, especially on the cheaper pumps. It consists of a flat plate with a tongue projecting at right angles and acting as a guide to hold the plate in place over the valve-opening (Figs. 2289, *C*, and 2290). A flake of rust or a particle of the spray mixture is liable to catch under the plate and prevent the valve from closing tightly. (3) *The ball valve* has a metal ball resting on the round opening (Fig. 2289, *D*). The upward movement of the liquid raises the ball but downward pressure only holds it more firmly in place. Usually a cage is constructed over the ball to prevent it from falling out of place. This type has generally proved the most satisfactory. The constant shifting of the ball tends to grind the valve-seat smooth and prevent any foreign particles from holding up the valve off the seat.

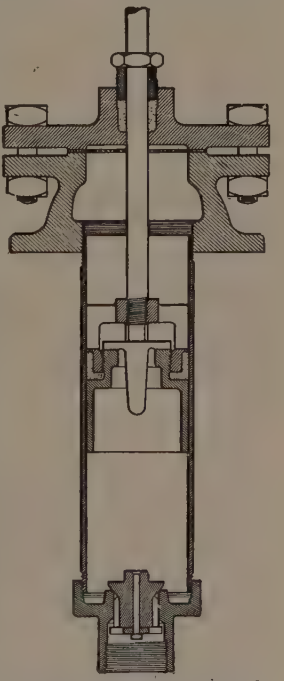
The air imprisoned in the pressure-tank acts as a spring to equalize the discharge. If the spray pulsates, it shows that the tank is too small or that it has become filled with water instead of air. Hand-pumps with a relatively long time between strokes of the plunger require a larger pressure-tank than do power-pumps, especially those having two and three cylinders. Most tanks are cast-iron and are very heavy; also, with cast-iron, there is always danger that a thin place will give way under pressure and cause serious trouble. Sheet-steel tanks are lighter and better. All power-pumps and many hand-pumps are supplied with a pressure-gauge. This is usually attached to the pressure-tank.

It is essential that a relief-valve be supplied since most power-pumps can easily be made to develop a pressure too high for the pressure-tank and hose to stand with safety. These valves are so constructed that they may be set to act at any desired pressure. The usual type is a ball or poppet valve held in place by a powerful spring whose tension can be regulated by a set-screw. When the pressure of the liquid on the valve becomes greater than the push of the spring, the valve is raised and the liquid then passes back through a pipe to the spray-tank. Such valves frequently cause trouble by the uneven wearing of the valve or valve-seat and the corrosion of the spring and working parts.

A few pumps are now supplied with relief-valves so arranged that when the valve is raised the pressure-tank and discharge are cut off from the pump, and the liquid leaving the pump flows freely back into the spray-tank. This causes no wear on the relief-valve and, since the pump does not have to work against pressure while the valve is in action, it leads to a considerable saving in power.

If valves held without loss, and no material leaked past the plunger-packing, the discharge of the pump would be equal to the area of the piston-head multiplied by the length of the stroke. Valves always leak back to a greater or less extent and the packing is seldom entirely tight, so that the actual and theoretical discharge are not the same. The difference between the two is called the "slippage." This will sometimes run as high as 50 per cent when the valves are not fitting tightly.

In using a hand-pump, it is less tiring to make a few strokes against heavy resistance than to make many strokes against a lighter resistance. For this reason pumps designed for hand use should have relatively large capacity. On the other hand, large capacity should not be obtained by increasing the diameter of the plunger beyond a certain point. A 2-inch plunger when working against 100 pounds pressure requires over 300 pounds of energy and even with the well-planned leverage of the long pump-handle this is about the maximum which may be demanded of the man on the handle.

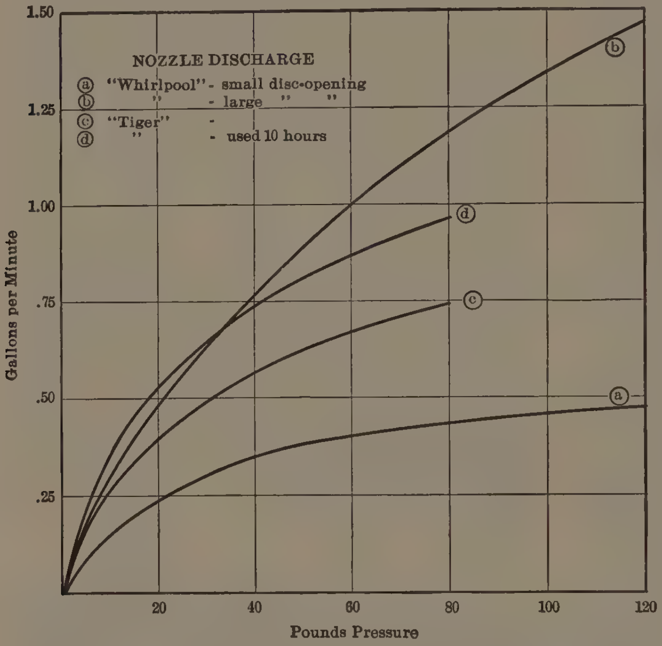


2290. Section of single-acting pump-cylinder showing poppet valves and inside packing.

In most pumps there is a narrow space left between the piston and the inner wall of the chamber. This is filled with some one of the many kinds of packing. One of the cheapest of these is made of loosely rolled tow strings and is sold as "candle-wicking." The best kinds are combinations of canvas and rubber. It is poor economy to buy cheap packing. The best does not last very long and the time lost in replacing poor packing would pay the slight extra cost of the better grades many times over.

No other part of the pump requires as frequent attention as the packing, therefore it is important that pumps should be so designed as to give ready access to the packing and also that some means should be provided for keeping it tight against the plunger.

Considering the packing only, pumps may be divided into two classes: outside-packed and inside-packed. An outside-packed pump is one in which the packing is set on the inside of the pump-cylinder and presses against the outside of the plunger (Fig. 2289, *E*). Such packing may usually be reached without removing the plunger. An inside-packed pump is one in which the packing is on the face of the plunger and presses against the inside of the pump-cylinder (Figs. 2289, *F*, and 2290) thus necessitating the removal of the plunger before it can be renewed.



2291. Diagram of the pressure and nozzle discharge. The amount of spray discharged increases rapidly at low pressures but more slowly at higher pressures. The amounts differ with different makes.

All parts, such as valves, plungers, and cylinder lining, which come in contact with spray materials, should be of brass, as this does not corrode so rapidly as steel. For inside-packed pumps, a bored cylinder is truer than a drawn tube and so pumps much easier because of the decreased friction.

A single-action pump is one which draws in the liquid as the plunger moves in one direction and drives it out as the plunger moves back. There are only two valves on such a pump. When two single-acting cylinders are used on the same pump it is called a two-cylinder, or duplex pump; one with three such cylinders is called a triplex pump.

A double-action pump is one in which the plunger, as it moves forward, pushes the liquid out ahead of it and at the same time draws in liquid back of it, then, as the plunger moves back, this second amount of liquid is pushed out and a new charge drawn in behind the plunger. Thus, a complete forward and backward movement of the plunger should discharge twice the capacity of the cylinder. Such a pump requires four valves and always has the packing on the face of the plunger.

Nozzles.

Spray liquids were first applied in a solid stream, though this was usually fine enough to be broken into drops by the resistance of the air. The next step forward was to place an obstruction at the end of the nozzle so that the stream, striking against this, was spattered out in fine drops. This method is still in use in the bordeaux nozzle, a device that gives a fan-shaped spray which at high pressures—two hundred pounds or more—is mist-like. It is not adapted to fungicides, but may be used in applying poison sprays.

In eddy-chamber nozzles, the liquid is thrown into a whirling, or cyclonic, motion in an eddy-chamber from which it is discharged through a small opening. Particles leave this opening in a direction tangent to their previous rotation, thus producing a cone of spray more or less uniformly filled. There are two ways in which the rotating motion is secured in the eddy-chamber: in one, the liquid enters the chamber through openings which have much the same pitch as the thread of a screw; in the other, the liquid enters through a passage tangent to the outer edge of the eddy-chamber. The screw-thread nozzles are usually straight nozzles, that is, the lines of entrance and exit are in the same direction, and are best adapted to use in the orchard. The tangent-entry nozzles are usually at right angles to the hose or spray-rod. Some of them are well adapted to field-spraying.

At low pressures the quantity of liquid discharged by a nozzle increases rapidly with increases of pressure, but at higher pressures the increase in discharge grows less as the pressure increases (see Fig. 2291). As the pressure increases, the size of the spray particles decreases.

The front face of all eddy-chambers is made by a thin disc in the center of which there is a round hole, called the discharge-disc opening. The smaller this opening, the finer are the particles of spray and also the smaller the volume discharged in any given time. A change from a small to a large opening may double or triple the discharge. The wear of a week of spraying may so enlarge the disc-opening as to increase the discharge from 50 to 100 per cent.

With hand-pumps it is usually desirable to use the lowest pressure which will give a good spray; therefore, with such pumps, the nozzle-discs should frequently be renewed and only those with small openings used. The discs cost but a few cents. Even with the same size of disc-opening, different makes of nozzles give a satisfactory mist-spray at various minimum pressures, ranging from as low as thirty to as high as one hundred pounds; therefore a knowledge of the minimum pressure at which a nozzle may be used is desirable when one is using a hand-pump where the pressure may, at times, run low.

Sufficient emphasis has not been laid upon the importance of securing the nozzle best adapted to each purpose. From what has been said above, it is readily seen that no small part of the success of the spraying, especially when hand-pumps are used, depends upon this factor; also the cost for labor and for materials may be decreased largely by judicious selection of nozzles and discharge-discs. One may thus regulate the amount and fineness of the spray according to the size and character of the trees to be sprayed, the outfit used, and the speed of the men who direct the nozzles.

Spray-hose.

The ordinary spray-hose is made up of one to seven layers of canvas embedded in rubber. The five- and seven-ply are the best for use with power-pumps but the three-ply may be used with hand-pumps.

For spraying purposes, it is not advisable to use a hose of more than ½-inch diameter. The added weight of the larger sizes makes them too awkward to use. For the trailing hose on a power-rig one of ⅜-inch diameter is best, but for the hand-pump the ½-inch size should be used because the loss of power through friction is less in the larger size.

When one expects to use trailers, and this should always be the plan in the apple orchard, the trailing hose should be long enough so that the tower-man can spray one tree while the trailer is finishing another. Fifty feet is the usual length for the apple orchard.

The couplings are the parts to which the hose is attached and which screw into the spray-rod and to the discharge-pipe of the pump. Improperly constructed couplings may cause considerable annoyance by permitting the hose to pull off. The shank over which the hose slips should be long enough so that two hose-bands may be used to clamp the hose upon it. The holding power of the shank is increased if the surface is ridged.

Additional equipment for orchard-spraying.

With most of the spray-nozzles now in use, it is necessary to bring the nozzle within 3 or 4 feet of the branch to be sprayed, or at least to raise it as high as the branch and let the spray drift with the wind. The use of extension spray-rods is a great help in this. The rod usually consists of a bamboo cane with an iron or aluminum core. The iron core is stronger and cheaper but because of its greater weight it is not so desirable as the aluminum, especially for the longer rods. An 8-foot rod is usually long enough for peaches, pears, and low-headed apples, but in many of the older orchards in New York and New England the 10 and 12-foot rods must be used.

With most of the sprays and especially so with the first codlin-moth spray, it is desirable to drive the liquid down on the tree with one of the rods. To do this it is necessary that one man be placed in a tower which is built over the pump or water-tank. The height of the tower depends upon the height of the trees to be sprayed. Usually the tower floor is from 5 to 7 feet above the hubs. If a high tower is put on a light rig there is danger of tipping over on rough ground. Many towers are now built with an iron framework and some of these fold back upon the tank when not in use. See pages 1057–1060; also page 1295.

The orchard spray rig usually carries from 100 to 200 gallons of spray solution. Various types of tanks are used for this purpose. The usual one is a half-round tank with the rounded part resting on the trucks; round tanks standing on end, and metal tanks are also used. For temporary use in a cheap rig, two fifty-gallon oil-barrels can be used.

Most of the spray mixtures contain matter in suspension and so some means of agitating the liquid is necessary. A common method is to place two paddles so that they will swing back and forth just over the bottom of the tank and connect them by a rod to the handle of the spray-pump. In some power-sprayers a shaft is run through the tank and two propellers are placed at opposite ends, each driving the liquid toward the center.

Types of spray-rigs.

The use of the hand-pump is confined to the garden, to young trees and small orchards. It is possible to spray 4 or 5 acres of mature apple trees with a hand-rig and do the work well, provided an efficient pump is used, but with such rigs it is usually necessary to use one more man than with power-rigs and to go somewhat slower. If a careful estimate of the relative costs were made before the hand-pump is abandoned for the power-rig, many would still continue to use the slower method and, even when a power-pump is purchased, the hand-pump should be kept in good condition to use in emergencies and when the ground is too soft for the heavier outfit.

If only a few bushes are to be sprayed, one-quart syringes, costing less than a dollar, can be secured. These work on the principle of the atomizer. For the garden and a few trees, bucket-pumps are satisfactory and inexpensive though it usually requires two men to use one. Some very satisfactory one-man pumps are now manufactured on the same principle as that used in the pressure-tank of the larger pumps. An air-tight tank, holding several gallons, is half filled with the spray mixture and the remaining air is compressed by an air-pump till the desired pressure is obtained.

The barrel-pump is the commonest form of hand-pump. Its popularity is due to its being cheap, compact, sold ready to use, and having sufficient capacity for the small home-orchard. On the other hand, the up-and-down motion of the handle is very tiring and high pressures can not be maintained for any length of time.

Separate pumps, mounted on a low base and operated by the back-and-forth movement of a long, upright handle are much easier to use and will develop a very satisfactory pressure. Such a pump, either with two cylinders or double-acting, will run four low-pressure nozzles and, by using one or two barrels for the spray-tank, an efficient outfit can be provided at a reasonable cost.

The traction-pump may be driven by the rotation of the axle for field-spraying, for the vineyard, the bush-fruit plantation, or for young trees where it is possible to keep the rig moving most of the time, but it is not possible to secure sufficient power in this way to spray large trees. The greatest trouble with many of the rigs of this type which have been on the market has been that they were too complicated and, therefore, troublesome to use, and costly. The present tendency is to make rigs which are much simpler. Usually a good type of hand-pump is used and is connected to the axle by means of a pump-jack or gearing. It is necessary to have a large-size pressure-tank in order to keep a uniform spray.

When the traction-sprayer is used for field-crops and occasionally in the vineyard-spraying, the nozzles are attached to an adjustable spray-boom. When such a boom is used, care should be taken to see that the sprays from adjacent nozzles overlap before reaching the plants to be sprayed.

Gas-engine rigs are for the large commercial orchard. If the engine is to be used to run the spray-pump only, it does not need to be over two and one-half horse-power and many engines are in use which develop but a single horse-power. Some of the rigs which are planned to run saws and grinders have as high as three and one-half horse-power but this greatly increases the weight.

Simplicity of construction is one of the most desirable features, as it means less trouble in running and fewer parts to wear out. A certain degree of lightness is also desirable, provided it is not secured by a sacrifice of needed strength. Heavy, cast bases are entirely unnecessary as the desired stability can be secured by lighter angle-irons. Most power rigs have a water-cooled engine and the consensus of opinion seems to favor this type. There are, however, one or two excellent air-cooled engines on the market that have given very satisfactory service. The demands that are put upon the engine are variable and for this reason a good governor is an important aid in maintaining a uniform pressure and avoiding engine-racing. It is probably for this reason—ease in governing speed—that the hit-and-miss spark is much more commonly used than the jump spark.

The lighter and cheaper rigs are frequently made by connecting an engine of about one horse-power with some one of the more efficient hand-pumps but on most of the power outfits the pumps are especially designed for this use and are of large capacity. Because of the greater steadiness of the discharge-pressure, the more uniform amount of power required from the engine, and their greater capacity, the triplex pumps are more generally used than the duplex.

Pump and engine are connected in various ways: with some a belt or chain is used, others are connected by gears, while still others are directly connected by a shaft in which a universal joint is usually placed to avoid trouble should the alignment not be exact. It is always advisable to have them so arranged that the engine can easily be disconnected and used independently. It is quite important that pump and engine should be so placed and the pump so designed that all valves are readily accessible and also that the plunger-packing can be reached and replaced quickly.

Spray-tanks of three sizes are used, 100, 150, and 200 gallons. Two hundred gallons of water weigh over 1,600 pounds and when this is added to the weight of the rig it frequently becomes impossible to haul a loaded sprayer of this size over soft ground; on the other hand, if the water-supply is not readily available, too much time is spent in filling the smaller tanks. The larger number of the more expensive outfits with large-capacity pumps have the largest size of tank and when the ground is too wet only half a tankful is used.

In spraying orchards on steep hillsides, it sometimes is impossible to use the tower without tipping over the rig. To avoid this, some manufacturers put out sprayers with the tank hung low so as to bring the center of gravity down nearer to the axle of the truck.

A few rigs have been made in which the liquid is placed in an air-tight tank that is connected to a cylinder of compressed carbon dioxide gas, such as is used in all soda-water fountains. The expansion of the gas entering the liquid-chamber supplies the necessary pressure. These sprayers give satisfaction when used with bordeaux mixture but, when used with lime and sulfur to which has been added arsenate of lead, a chemical action takes place with the gas which releases soluble arsenic and thus causes serious burning on the foliage sprayed.

Some growers, whose orchards are on steep hillsides and where the land is too rough to take a sprayer of the usual weight, have had satisfactory results from the use of compressed air. Two metal tanks are mounted on a low two-wheeled truck. One of these is filled with the spray solution and, with a compressor which is mounted at the filling-platform, air is pumped into the second tank till a pressure of 300 to 400 pounds is reached. This pressure is then gradually turned into the liquid-tank as the solution is sprayed out. The greatest part of the cost is in the engine and compressor, but if these are used to run several sprayers the final cost is not high. There are some mechanical difficulties still to be overcome before these rigs are entirely satisfactory, yet they illustrate a method that has much to commend it.

Tools, repair parts and extras.

There are few operations on the farm in which the efficiency of the work depends as much upon the time at which it is performed as in spraying. This makes it essential that care be taken to prevent loss of time through minor troubles. The value of time spent in hunting for a certain tool to tighten a connection may be sufficient to buy the tool many times over. The first requirement is a kit of tools consisting of hammer, two wrenches,—one a pipe-wrench,—screw-driver, cold-chisel, and pliers. A collection of nuts, bolts and washers and a few feet of fine and heavy wire should be added to this. A supply of durable packing sufficient to repack all the pump-cylinders should be on hand at all times. It is well to have a piece of rubber gasket-cloth from which washers and gaskets for unions and other connections can be cut. A supply of new nozzles, nozzle-washers and especially nozzle-discs is essential. The breaking of an extension-rod is of such frequent occurrence that it is desirable to have one in reserve for such emergencies. Wherever hose is used an extra length should be carried.

With a power rig, the ignition system is usually the cause of most of the trouble. Batteries need to be replaced at least once in a season and, with a jump spark, a new spark-plug is occasionally needed. It seems almost needless to say that a plentiful supply—and liberal use—of oil and cup-grease is necessary, yet many machines are injured by lack of this.

In using a traction-sprayer for different field-crops and especially if the same sprayer is used in the vineyard, it is frequently desirable to change the arrangement of the nozzles. With a hack-saw, file, ¼-inch pipe thread-cutters, a few feet of ¼-inch pipe and a few couplings, nipples, unions and elbows, this can quickly be done.

Mixing-platforms, boilers, filling devices.

In most cases where bordeaux mixture is used, it is made on the farm as it is needed. In such cases the work is simplified by the use of a mixing-platform with the floor high enough so that the liquid can be poured directly into the spray-tank when the rig is driven to the platform. There should be space for at least four barrels. Such a platform should be placed so that water is readily available. If there is no windmill or power-driven pump, the platform should be directly over a well with the pump mounted on the floor.

A similar platform is very convenient where lime-sulfur is to be made on the farm, using steam for the boiling. The boiler can be placed on the ground or in an adjacent building and the steam piped to each barrel. For this work any boiler may be used which can develop ten or fifteen pounds pressure.

When lime-sulfur is to be made by direct heat instead of steam, any standard feed-cooker or simply a large iron kettle can be used. When any considerable amount of liquid is to be boiled, it adds greatly to the convenience if water can be piped directly to the kettle and if the lime-sulfur can be emptied directly into barrels by a siphon or a discharge-pipe from the boiler.

It is not uncommon for it to take longer to drive from the orchard to the water-supply, fill the tank and return than it takes to spray out the tank. Efficiency in spraying necessitates a convenient water-supply. If the mixing-platform is near enough, it can be used as a reservoir from which a tank-load can quickly be secured. Some of the manufacturers are now equipping rigs with either an auxiliary filling-pump or a device working on the principle of the injector and taking the power from the spray-pump. These are very convenient where an elevated supply of water is not possible. Where a nearby water-supply can not be secured it is best to haul the water to the sprayer in tank-wagons or in barrels.

R. D. Anthony.

MACKÀYA: *Asystasia.*

MACLEÀNIA (after John Maclean, British merchant at Lima, Peru, patron of botany). *Ericàceæ.* About a dozen species of shrubs in the mountains from Mexico to Peru, useful for ornament under glass but little known in cultivation. They have clusters of brick-red or crimson, tubular flowers each an inch or more long, and often bear tinted foliage.

Leaves evergreen, alternate, short-stalked, entire: corollas strongly 5-angled, and the 5 tips short, triangular, erect or spreading and more or less yellow; stamens 10, much shorter than the corolla; disk ring-like or not evident; ovary 5–6-celled, the style filiform; ovules many.—One species, *M. insignis*, is currently offered abroad. Macleanias are probably of difficult cult. *M. speciosissima* in a large pot on a shelf near the glass, so that its branches may hang gracefully, should be a very striking subject. *M. pulchra* has the same habit and color of fls., but is perhaps less desirable. *M. punctata* is perhaps the most desirable of those with erect branches and stiff habit. This may be tried in a warmhouse border, with good drainage and shallow soil, as some of these macleanias have thick fleshy roots and the fibrous parts of the roots are said to keep near the surface.

insígnis, Mart. & Gal. Young foliage on spring growths with tints of red; a small evergreen shrub: lvs. 1–2 in. long, oblong or elliptic, obtuse or subacute, coriaceous: fls. axillary, scarlet, the cylindrical corolla 1½ in. long; calyx short, minutely 5-toothed; corolla-lobes small and spreading; filaments united to form a tube. Mex. B.M. 7694. G. 32:351; 36:517.—A handsome plant both in foliage and fl. for greenhouse. Said to have been first discovered growing epiphytically on oaks at an elevation of 4,000–6,000 ft. in Province of Vera Cruz.

A number of macleanias mentioned in the literature do not appear to be regularly in the trade, as: *M. angulàta*, Hook. Lvs. ovate, rather coriaceous, obtuse and entire, those on the young shoots delicate and with a deep tinge of red: fls. axillary, in 3's; corolla nearly 1 in. long, bright red with a yellow limb. contracted at the mouth, with 5 prominent angles or ridges. Peru. B.M. 3979. H.U. 4, p. 327.—*M. longiflòra*, Lindl. Near M. angulata, but with longer and narrower lvs., and the fls. less contracted at the orifice and the lobes not yellow. B.R. 30:25. H.U. 6, p. 100.—*M. púlchra*, Hook. Branches long and drooping: lvs. rather large, glossy, elliptic or oblong, short-petioled, 5-nerved: fls. aggregated in the axils, large, about 1¾ in. long, the corolla-tube bright scarlet and the limb yellow. Colombia. B.M. 5465.—*M. punctàta*, Hook. Lvs. somewhat secund, sessile or practically so, oval, obtuse and entire, glossy and dotted: fls. crowded in upper axils, on red clavate peduncles; corolla 1 in. long, swollen below, rose-red and the upper part white tinged with yellow. Andes. B.M. 4426. G.W. 12, p. 774.—*M. speciosíssima*, Hook. Most beautiful plant in bloom: straggling shrub, with long pendent branches: lvs. distichous, 2 in. or more long, ovate or oblong-ovate, obtuse, entire: fls. many, drooping in axillary fascicles; corolla 1¼ in. long, bright scarlet, yellow above, contracted below the small limb. Colombia. B.M. 5453.

L. H. B.

2292. Osage orange fruit.—Maclura pomifera. (×½)

MACLÈYA: *Bocconia.*

MACLUDRÀNIA. *Moràceæ.* A bigeneric hybrid between *Maclura pomifera* var. *inermis* and *Cudrania tricuspidata.* (See Vol. II. p. 911.) *M. hýbrida*, André, is a small tree with yellowish furrowed bark and short woody spines: lvs. alternate, glabrous, violet beneath, oval, long-acuminate.

MACLÙRA (after Wm. Maclure, an American geologist). Syn. *Tóxylon. Moràceæ.* Osage Orange. Bowwood. Tree chiefly grown as a hedge plant, also planted as an ornamental tree for its handsome bright green foliage and the conspicuous orange-like fruit.

Deciduous, with milky sap: branches with axillary thorns: lvs. alternate, entire, slender-petioled, with minute stipules: fls. diœcious, minute, apetalous; calyx 4-lobed; the staminate pedicelled, in pendulous racemes on spur-like branchlets of the previous year; stamens 4; pistillate sessile, in axillary dense globose heads on short peduncles; ovary 1-celled with a long filiform plumose stigma: drupelets oblong, collected into a globose compound; fr. mamillate on the surface.—One species in N. Amer. It is sometimes described under Toxylon, but this name is replaced with Maclura by the "nomina conservanda" of the international rules.

The osage orange is a medium-sized spiny tree with spreading branches, forming an open irregular head, with rather large bright green leaves changing to clear yellow in fall and with inconspicuous greenish flowers followed by greenish yellow orange-like but inedible fruits in the pistillate tree. It is hardy as far north as Massachusetts. It is not particular as to the soil; its roots are very long and voracious feeders. Much planted for hedges chiefly in the Middle West. The bark of the root is used as a yellow dye; that of the trunk sometimes for tanning leather. In Europe the tree is sometimes grown as food for the silkworm. Propagation is usually by seeds, which germinate readily; also by root-cuttings and by greenwood cuttings under glass.

pomífera, Schneid. (*M. aurantìaca*, Nutt. *Tóxylon pomíferum*, Raf.). Fig. 2292. Tree, sometimes to 60 ft., with furrowed dark orange-colored bark: branchlets light green, soon glabrous: spines 2–3 in. long: lvs. ovate to oblong-lanceolate, acuminate, soon becoming glabrous, lustrous above, 2–6 in. long: racemes of staminate fls. 1–1½ in. long; heads of pistillate fls. ¾–1 in. across: fr. subglobose, 4–5 in. across, ripening in autumn and soon falling. May, June. Ark. to Texas. S.S. 7:322, 323. G.C. III. 16:693. G.M. 33:808, 809. V. 437. Var. **inérmis,** Rehd. (*M. aurantìaca* var. *inérmis*, André). A form with spineless branches. R.H. 1896, p. 33.

Alfred Rehder.

The osage orange, before the advent of wire fences, was an extremely popular hedge plant, meeting general requirements better than any other plant suitable to our climate. It is used considerably, and when properly attended to from the start makes a hedge in a short time of a fairly defensive nature. Most dealers in tree seeds keep seeds of the osage orange, and those who grow the plants procure the seed in spring, drilling it in rows. The osage orange grows readily from seed, even when the latter is a year old. The sowing in rows gives the seedlings a chance to become stocky by fall, and plants 2 feet high the first year are not uncommon. These one-year-old plants are quite good enough for hedging. Nurserymen who grow them for sale usually dig the plants in the fall, storing them away in a cool cellar, the roots buried in sand. They are then sorted into two grades, which compose first- and second-class plants. At the time of grading, the tops are chopped off somewhat, leaving about 6 inches of length only. This fits them for planting without more cutting.

The place where a hedge is desired should be well cleared of all weeds. If cultivated for a year in advance, so much the better, as it will make the keeping down of weeds a much easier task.

There are two ways of planting a hedge; viz., single row and double row. The double row is made by setting the plants 9 inches apart each way, the plants in the second row coming between those in the first row, forming a zigzag line. The single row, however, is good enough, and is much easier to cultivate and keep clear of weeds. In single rows set the plants 6 inches apart.

The soil need not be over-rich for the osage orange. The plant is a strong grower naturally, and soil in fair condition will give a growth more tractable to form a good hedge than a rank growth from rich soil.

When dug, the osage plants have very long roots, and the ends of these may be chopped off without disadvantage. If the plants are held in bunches and the roots chopped to an even length, the setting will be an easy task. The tops will have been already cut off if treated in the way above suggested.

Beyond cultivation of the plants, nothing is required the first year. By fall a good growth should have been made, and toward spring this should be cut back, leaving about 6 inches of the young growth. The season following, more care must be given to forming a hedge. When in full growth, say in July, shear off the tops of the plants. This will cause the side shoots to develop; and it is these side shoots which will form the base of the hedge. Another light trimming should be given when growth is over for the season, to bring the plants into a hedge shape. Much the same work will be required every year,—a trimming when growth is in full swing to make the hedge bushy, and another later on to shape it.

The proper shape for a hedge is the conical form, though it may be flat-sided or in any shape desired, provided the upper branches never overlap the lower.

Of late years a system of planting the osage orange differing from the one described has been followed by some. Strong two-year-old plants are procured and are planted in a slanting position. As the new growth is made it rises in an upright way as usual, and this produces a lattice-like appearance of the branches, and a very strong hedge. It is certainly stronger than a common hedge, and yet a common one properly looked after forms a defensive fence, meeting all requirements, and costs not nearly so much as the other. See *Hedges*.

Joseph Meehan.

MACÒDES (from *makos*, length; on account of the long labellum). *Orchidàceæ*. A small group of orchids of the habit of Anœctochilus.

Terrestrial herbs, with few variegated petioled lvs. at the base, and small fls. borne in a long raceme: sepals and narrower petals spreading; labellum ventricose, with 2 small lateral lobes and 2 calli inside, turned to one side; column short, twisted in the opposite direction, with 2 narrow, erect appendages.—Two or 3 species, with cult. requirements similar to those of Anœctochilus.

Pétola, Lindl. (*Anœctochìlus Veitchiànus*, Hort. *A. Pétola*, Hort.). Fls. greenish, inconspicuous: lvs. ovate, 2–3 in. long, reticulated, with golden yellow veins. Java. R.B. 21:61. G. 27:55. O.R. 17:73.

javánica, Hook. f. Sts. creeping or suberect, 6–8 in. long, rosy red: lvs. 3 in. long, 2 in. wide, dark velvety green above, with the nerves pale green and with white reticulations, reddish on the lower surface: fls. orange-red, white-tipped. Java. G.C. III. 39:216. B.M. 7037.

George V. Nash.†

MACROCHÓRDIUM (*long* or *large tube*). *Bromeliàceæ*. A few S. American plants usually referred to Æchmea. *M. strictum*, Beer, is referred by Mez to *Æchmea bromeliæfolia*, Baker. (See p. 222, Vol. I.) The species is characterized by white-scurfy lvs., simple dense, woolly spikes overtopping the foliage: fls. with yellowish green calyx and small exserted purple-black petals. *M. luteum*, Regel & Lind.= *Æchmea calyculata; M. pulchrum*, Beer, and *M. tinctorium*, De Vriese, also =*Æchmea bromeliæfolia*.

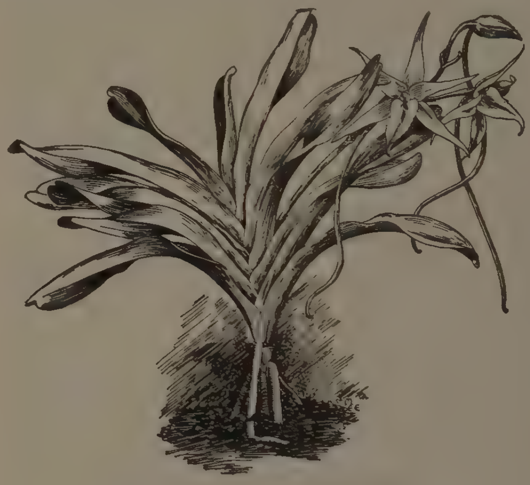
MACROPÌPER (*long* or *large piper*). *Piperàceæ*. A few shrubs of the Pacific Isls., by some included in Piper, but separated by the monopodial rather than sympodial growth of the flowering shoots, and by minor characters. Probably none is in the trade, although a form of the following is mentioned in recent horticultural literature. *M. excélsum*, Miq. (*Pìper excélsum*, Forst.). Glabrous densely branched aromatic shrub or small tree to 20 ft., in Tahiti, Norfolk Isl., New Zeal., and elsewhere: branches jointed and swollen: lvs. alternate, stalked, broad-ovate or broader, 7-nerved, yellow-green, the petiole winged below: spikes dense, solitary or in 2's, bearing minute unisexual fls.; stamens 2 or 3; stigmas 3 or 4: fr. small yellow berries, densely compacted. Var. *aùreo-pictum*, Hort., has a large cream-colored or yellow blotch on the lf. G.Z. 21, p. 74.

For *M. methysticum*, Hook & Arn., and further discussion, see *Piper*.

L. H. B.

MACROPLÉCTRUM (Greek, *long-spurred*). *Orchidàceæ*. Caulescent plants, in habit and cultural requirements like Vanda, with numerous distichous leaves, the flowers with long spurs.

Sepals and petals similar, spreading; lip rigidly attached to the base of the column, entire; column short and thick; pollinia 2, upon separate and distinct membranous caudicles.—Several species in Madagascar and the Mascarine Isls. In *M. sesquipedale*, the long spur or tail-like appendage is sometimes 18 in. long. Darwin predicted when he saw the plant first that a moth would be found some day in Madagascar with a tongue long enough to reach down to the nectar, and it was, years afterward.



2293. Macroplectrum sesquipedale.

sesquipedàle, Pfitz. (*Angræcum sesquipedàle*, Thouars. *Aëránthus sesquipedàlis*, Lindl.). Fig. 2293. Sts. 2–3 ft. tall: lvs. oblong-ligulate, 12 in. long and up to 2 in. broad, unequally 2-lobed: peduncle 2–5-fld.; fls. 5–7 in. across, fleshy, ivory-white; sepals and petals similar, acuminate; lip oblong-ovate, cordate, acuminate, irregularly serrate. Madagascar. A.G. 13:217. A.F. 7:831. Gn. 2, p. 5. F.S. 14:1413. B.M. 5113. G.M. 38:294; 47:494; 49:95. O.R. 9:49. C.L.A. 17:429. G. 18:365. G.C. III. 45:399. Gn.W. 10:421. Gt. 58, p. 55. J.H. III. 44:337; 64:393.

Leònis, Nash (*Angræcum Leònis*, Veitch. *Aëránthus Leònis*, Reichb. *Angræcum Humblòtii*, Reichb. f.). Lvs. falcate, fleshy, equitant, flattened laterally: raceme of 8 or less white fls., 2–3 in. across, on winged pedicels; sepals and petals lanceolate; lip cordate, cuspidate; spur 4–6 in. long, curiously bent a part way down in the direction of the fl. Comoro Isl. G.C. II. 24:80, 81.

George V. Nash.

MACROSCÈPIS (Greek, *long* or *large*, and *to cover*). *Asclepiadàceæ*. Tropical American climbers, somewhat grown in the warmhouse.

Tall twining, setose-hirsute: lvs. opposite, large, cordate: cymes crowded; fls. rather large and usually showy; calyx about 5-parted; corolla-tube ovoid or broadly cylindrical and constricted at the throat;

limb 5-lobed, spreading; scales of the crown 5, inflexed under the throat of the fleshy corolla; stamens inserted near base of tube, the filaments connate into a short tube: follicles hard and thick.—Species few.

ellíptica, N. E. Br. Twining, long-hirsute: lvs. 6–7 in. long, elliptic, cuspidate-acuminate, cordate at base, long-petioled: fls. 8–10 in an umbel, each fl. about 1 in. diam., resembling those of *Hoya carnosa* in shape, soft velvety brown; sepals about ⅛in. long, oblong-lanceolate; corolla 5-lobed, green at the throat; lobes of the crown fleshy, deltoid, incurved, whitish. Brazil.

L. H. B.

MACROSTÍGMA: *Tupistra.*

MACROTÒMIA: *Arnebia (A. echioides)*, by some kept as a distinct genus.

MACROZÀMIA (Greek, *long* or *large, Zamia*). *Cycadàceæ.* Cycas-like plants, grown under glass and suitable for the open far South.

The genus is less allied to Cycas than to Dioon and Encephalartos, from which it is distinguished by the following characters: lvs. pinnate: scales of the female cones peltate, the shield thickened, ascending, usually produced into an erect, acuminate blade. It is to Austral. what Encephalartos is to S. and Cent. Afr., but that genus differs, according to Bentham, in much more rigid habit and very obtuse or truncate cone-scales. It is closely allied to the American Zamia, which differs in its cones and the articulate attachment of the pinnæ. —A dozen and more species in Austral., which, like most of the members of this order, make noble foliage plants for private conservatories. They have the trunk and lvs. of cycas, except that the pinnæ have no midrib but are more or less distinctly striate, especially on the under side, with several parallel equal veins, the whole lf. occasionally twisted in some species, but not constantly so in any one. The treatment in this account is adapted from Bentham.

Macrozamias are representative rather than useful subjects, and not frequently seen. They combine poorly in any scheme of plant and flower decoration; but as single specimens, they always attract attention, and in a grouping of similar subjects, or with aloes, agaves and yuccas they make an effective combination. Their culture is easy. Sandy soil, with charcoal, to keep the soil sweet, ordinary greenhouse temperature, plenty of water during the growing season, which corresponds to our summer, and rest in winter, are the essentials. (T. D. Hatfield.)

A. *Pinnæ very narrow, often nearly terete: cones small, rarely above 4 in.; fr. very woolly.*

Paulo-Guiliélmi, Hill & Muell. (*M. plumòsa*, A. Mohr.). Trunk short, scarcely protruding from the ground, bearing the woolly bases of old petioles: lvs. 1–3 ft. long, the rachis narrow and often flat on top; pinnæ many, very narrow or even almost terete, contracted at the base: male cones about 3 in. long; females about 4 in. long and half as thick. R.H. 1877, p. 254. G.Z. 20, p. 64.

AA. *Pinnæ flat, inserted on the margins of the rachis, contracted at the base: cones 4–10 in., glabrous.*

B. *Rachis of lvs. usually raised longitudinally between the pinnæ: cone-scales much flattened.*

spiràlis, Miq. Trunk short: lvs. 2–4 ft. long: pinnæ with mostly longitudinal insertion, flat, straight or slightly falcate, to 8 or 10 in. long, slightly contracted and callous at base, lower margin slightly decurrent, marked on underside with parallel longitudinal veins: male cones 6–10 in. long, with much flattened scales; female cones usually shorter and thicker than the males, the scales with incurved short point. G.C. III. 13:74. —*M. cylíndrica*, Hort., Bentham considers a doubtful variety of *M. spiralis*, being smaller, with the narrow foliage nearly of *M. Paulo-Guilielmi*, but with a glabrous trunk and more terete rachis. *M. coràllipes*, Hook. f., has the callous base of the pinnæ bright red. B.M. 5943. G.Z. 21, p. 170.

BB. *Rachis of lvs. very flat between the pinnæ and often broad: cone-scales very thick.*

Miquélii, F. Muell. Typically with base of petioles woolly, rachis broad and flat and cone-scales thick, but variable: lvs. 2–4 ft. long; pinnæ usually longer than in *M. spiralis*, straight or falcate, the longitudinal veins finer and less prominent: male cones 6–8 in. long, cylindrical; female about as long and thicker, the scales mostly with a long point. *M. Mackénzei* is apparently a form of this species. G.Z. 22, p. 49.

AAA. *Pinnæ inserted by their broad base along the center of the upper surface of the rachis, scarcely separated by a very narrow line: cones large, pubescent, the scale points broad and often recurved.*

Peroffskyàna, Miq. (*M. Perowskiàna* and *M. Dénisonii*, F. Muell.). Large, the trunk 18–20 ft. high and 1 ft. or more diam.: lvs. 7–12 ft. long, with angular petioles; pinnæ 1–2 ft. long and ½in. broad, the parallel veins finely marked and very obscure, only slightly contracted at base: male cones ovoid, 4–6 in. long and 3–4 in. diam.; females 8–16 in. long and very thick.

Wilhelm Miller.
L. H. B.†

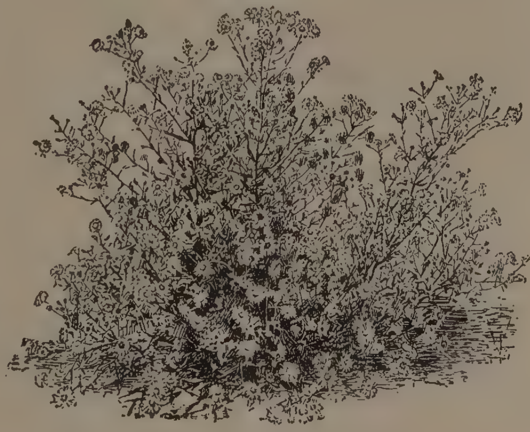
MADDÈNIA (after Major E. Madden, who wrote on Indian botany). *Rosàceæ*, subfam. *Prùneæ.* A genus of 5 shrubs or small trees allied to Prunus, especially to the section Padus, differing chiefly in the polygamous apetalous fls. with usually 10 small sepals, the staminate often with 2 abortive pistils; stamens 25–40. Only the following species is in cult., and has proved hardy at the Arnold Arboretum, but has no particular ornamental qualities. Cult. like Prunus. **M. hypoxántha,** Koehne. Shrub or small tree, to 20 ft.: branchlets sparingly hairy: lvs. membranous, oblong to lanceolate, acuminate, cordate to broadly cuneate at the base, doubly and sharply serrate, glabrous above, pubescent on the veins and bright or yellowish green beneath, 3–6 in. long, with 12–20 pairs of veins: racemes long-peduncled, dense and short; calyx about ⅓in. long, with 10 unequal small teeth, stamens about 25: drupe subglobose, black, little over ⅓in. long. May; fr. in July. W. China.

Alfred Rehder.

MADDER: Root of *Rubia tinctorum.*

MADEIRA VINE: *Boussingaultia.*

MÀDIA (*Madi*, the Chilean name of the common species). *Compósitæ.* Yellow-flowered herbs confined to the western part of the American continent, sometimes grown in the flower-garden.



2294. Madia elegans.

The nearest genus of garden value is Layia, from which Madia is distinguished by the following characters: involucre deeply sulcate, bracts strongly infolding and thus inclosing the achenes of the rays which are laterally compressed: achenes of the disk fertile or sterile. Their fls. are remarkable for closing in the sunshine, and opening in the morning or evening. Species about a dozen.

They are all called tarweeds from their glandular, viscid, heavily-scented foliage, the common tarweed of California being var. *congesta* of *M. sativa*, which is a useful annual plant for sheep pastures in dry, warm soil. *M. elegans* is an interesting ornamental annual. It has a graceful open habit (see Fig. 2294) and distinct flowers (Fig. 2295), which become more numerous as the summer advances.

A. *Rays showy.*

B. *Plant annual: lvs. chiefly alternate: pappus none.*

élegans, D. Don. Figs. 2294, 2295. Height 1–4 ft.: lvs. linear or lanceolate, mostly entire: rays acutely 3-lobed, yellow throughout or with a brown spot at the base. Calif. and Ore. to Nev. B.M. 3548. B.R. 1458.—Needs a shady place.

2295. Madia elegans. (Natural size)

BB. *Plant perennial: lvs. mostly opposite: pappus present in disk-fls.*

madioìdes, Greene (*Anìsocárpus madioìdes*, Nutt. *Màdia Núttallii*, Gray). Slender, not over 1–2 ft.: lvs. linear-lanceolate, sometimes dentate: heads paniculate, usually short-stalked. Woods, Brit. Col. to Monterey, Calif.

AA. *Rays inconspicuous, about 2 lines long.*

satìva, Molina. A glandular and sticky, heavy-scented annual about 1–3 ft.: lvs. from broadly lanceolate to linear: rays 5–12, with honey-yellow ligules about ¼in. long. Ore., Calif., Chile, perhaps native in S. Amer.

N. Taylor.†

MÆSA (from *maáss*, the Arabian name of *Mæsa lanceolata*). *Myrsinàceæ.* A group of about 100 shrubs found throughout the tropical and subtropical regions, except Amer., differing from all other Myrsinaceæ in the many-seeded fr. and the half-superior ovary. Lvs. alternate, petioled, entire or serrate, without stipules: fls. small, white, in axillary racemes or panicles, rarely terminal; calyx 5-lobed; corolla campanulate or urceolate, 5-lobed; stamens affixed to the corolla-tube, opposite the lobes, included; ovary half-superior, 1-celled, with many ovules on a central placenta; style cylindric with capitate stigma: fr. berry-like, many-seeded, crowned by the persistent calyx and style. The following species are occasionally grown in S. Calif. and *M. argentea* as a greenhouse shrub in botanical gardens in Eu. Prop. by seeds and probably by cuttings. **M. argéntea,** Wall. Large shrub with stout branches, densely brownish pubescent while young: lvs. membranous, elliptic to elliptic-oblong, dentate, dull green above and more or less pubescent on both sides, 4–8 in. long: fls. white, scarcely ⅙in. long, in short racemes ½–1 in. long: fr. globose, whitish, ⅙in. across or less. Himalayas. **M. índica,** Wall. Tree, to 30 ft.: lvs. coriaceous, glabrous, elliptic, dentate, about 5 in. long: racemes axillary, shorter than lvs. India. Bears edible berries. **M. macrophýlla,** Wall. Shrub, 6–14 ft.: branches pubescent: lvs. broadly elliptic, softly hairy on both surfaces, dentate, to 6 in.: racemes panicled, often as long as lvs.: berries rusty red, not edible. India.

Alfred Rehder.

MAGNÒLIA (after Pierre Magnol, professor of medicine and director of the botanic garden at Montpellier, 1638–1715). *Magnoliàceæ.* Woody plants grown chiefly for their showy white, pink or purple flowers and also for their handsome foliage; mostly spring-blooming.

Deciduous or evergreen trees and shrubs, with rather stout branches marked with conspicuous lf.-scars: lvs. alternate, entire; the stipules usually adnate to the petiole and inclosing the young successive lf.: fls. terminal, solitary, the buds inclosed in a stipular spathe; sepals 3, often petaloid; petals 6–15; stamens and carpels numerous, the latter connate into a spindle, developing into a cone-like somewhat fleshy or leathery fr., with dehiscent, 1–2 seeded carpels; the large, usually scarlet seeds often suspended for a time from the fr. by thin threads.—About 35 species in N. and Cent. Amer., Himalayas and E. Asia. The wood is close-grained, usually light and satiny, but not durable; that of *M. hypoleuca* is much used in Japan for lacquered ware; the bark and fr. of some species have been used medicinally as a tonic and stimulant.

The magnolias are highly ornamental and popular, with large white, pink or purple, rarely yellowish flowers, often fragrant; the cone-shaped fruits are often pink or scarlet and very decorative. Most of the deciduous species are fairly hardy, at least in sheltered positions, as far north as northern New York and Massachusetts, and *M. acuminata*, *M. Kobus* and *M. stellata* even farther north, while *M. Campbellii* is the most tender. Of the evergreen species, *M. grandiflora*, one of the most beautiful native trees, is precariously hardy north to Philadelphia. The Asiatic deciduous species are among the most showy and striking of the early-flowering trees and shrubs; the earliest is the shrubby *M. stellata*, blooming in mild climates in March, and after this *M. denudata* comes into bloom, closely followed by *M. Soulangeana* and after this *M. liliflora*. The handsomest of the deciduous species is probably *M. hypoleuca*, with the very large leaves silvery white below and with showy, sweet-scented flowers; also the American *M. macrophylla* and *M. tripetala* are conspicuous by their very large foliage. The magnolias are usually planted as single specimens on the lawn, and there are, perhaps, no plants more striking against a background of dark green conifers. Some species, as *M. grandiflora* in the South and *M. acuminata* farther north, are fine avenue trees. The magnolias thrive best in somewhat rich, moderately moist and porous soil, preferring sandy or peaty loam, but some kinds which usually grow naturally on the borders of swamps, as *M. glauca*, thrive as well in moist and swampy situations. Transplanting is difficult and is most successfully performed just when the new growth is starting. Propagation is by seeds sown immediately or stratified, and by layers of last year's growth put down in spring and tongued or notched. Layers are usually severed and transplanted the following spring, but as many of them die after transplanting, it is a safer way to take them off early in July, when the new growth has ripened, plant them in pots and keep in a close frame until they are established. Varieties and rarer kinds are often veneer- or side-grafted in early spring or summer on potted stock in the greenhouse or frame; as a stock *M. tripetala* is perhaps the best on account of its better fibrous roots, which render transplanting safer, but *M. acuminata* is also a good stock. Sometimes increased by greenwood cuttings taken with a heel and handled under glass.

Magnolias in the South.

Evergreen kinds. (P. J. Berckmans.)

Among the finest magnolias cultivated in the South are the two native evergreen species, *M. grandiflora* and

LXVII. Magnolia Soulangeana, the commonest hybrid magnolia in the North.

M. glauca, and the exotics *M. Coco* (*M. pumila*) and *M. fuscata*, the last being now referred to Michelia. *Magnolia grandiflora* is a noble tree. It is native of the middle and southern sections of Georgia, South Carolina, Alabama, Louisiana and the upper districts of Florida, and is recognized as one of the grandest of all broad-leaved evergreen trees. In its native habitat it attains a height of 75 to 100 feet, with very large, oval or lanceolate coriaceous leaves. The latter vary, however, from very broad to rather narrow, some with a rusty under surface, others quite smooth. The flowers vary also in size, the largest frequently measuring 10 to 12 inches in diameter when fully expanded; others do not attain more than half that size. They appear early in May, in some sections during the latter part of April, and continue until the end of June. Some trees produce a few flowers during August, and even as late as October, but these are exceptions. Each flower lasts from two to four days, when the petals fall and the cone-like fruit appears. This gradually increases in size until September, when the bright coral-red seeds are detached and hang on long filaments. The seed should be gathered when fully ripe, put in dry sand until February in the South, then in moist sand for a week or ten days, when the resinous cuticle can be removed by washing. Sow the cleaned seed in a box or coldframe, and as the plants show their second leaves pot off in small pots. In July, give a larger-sized pot, and the plants will be sufficiently large to plant in permanent place during the following autumn or winter. It is always advisable to take pot-grown plants, as they succeed better than plants taken up with bare roots. Magnolias are voracious feeders, and require rich soil and an abundance of plant-food. Their roots extend to a great length, and to bring out the stately beauty of this tree they should be given ample space. The wood is white, and valued for cabinet-work. There are many forms cultivated in European nurseries, their main characteristics being in the size and form of the leaves and size of flowers. They are propagated by grafting, either by inarching or cleft- or tongue-graft. The latter should be done under glass, taking two-year-old pot-grown seedlings. The fragrance of the flowers varies also, some flowers being more pungent than others, but, as a rule, the fragrance is pleasant. The principal varieties are *M. grandiflora* var. *gloriosa*, with flowers often measuring 14 inches in diameter; foliage broad and massive, brown on under surface. The tree seldom grows beyond 40 feet. Var. *præcox*, or early-flowering. Var. *rotundifolia*, with very dark green roundish leaves, rusty underneath.

Magnolia glauca, the sweet bay, is an evergreen tree in the southern states, becoming deciduous northward. It attains a height of 30 feet in rich bottoms or swampy lands: leaves oval, long or elliptical, with a glaucous under surface: flowers white, 3 to 4 inches in diameter, very fragrant, and produced from May to July. This tree is not sufficiently appreciated as an ornamental in landscape gardening.

Magnolia Coco (*M. pumila*, or *Talauma pumila*) is a very dwarf Chinese species, seldom growing more than 4 or 5 feet high: leaves smooth, elliptical, sharp-pointed, coriaceous: flowers 1 to 1½ inches in diameter, white or slightly tinged green, with six to nine fleshy petals, which drop soon after the flowers expand. The fragrance is intense at night, and resembles a ripe pineapple. It thrives best in a rich, partially shaded soil, but a frost of 10° below the freezing-point will injure it. It is therefore best to grow it as a conservatory plant. Propagate by ripened wood cuttings in bottom heat. As this plant is in bloom during nearly the whole year, and its delicate fragrance is unsurpassed, it is strange that it is so little known.

Deciduous kinds. (L. A. Berckmans.)

Magnolia acuminata (cucumber tree) is an upright-growing variety, with spreading branches, especially desirable for the upper sections, where it attains an immense size: leaves oblong, bright green: greenish yellow flowers produced in late spring.

Magnolia cordata is an exceedingly rare variety found only near Augusta, Georgia, and the western part of South Carolina: leaves oval: flowers about 3 inches long, lemon-yellow. Forms a small tree. Does well in sandy soil.

Magnolia denudata (Yulan) is a native of China with pure white flowers produced in early spring before the leaves appear. It attains an ultimate height of not more than 20 feet.

Magnolia Fraseri has leaves 8 to 12 inches long and produces white flowers 3 to 4 inches wide. This is a hardy variety and is especially adapted to the upper section. Attains a height of 25 to 50 feet. Found naturally from Virginia to Florida.

2296. Magnolia Thompsoniana. (×¼)

Magnolia Kobus, from Japan, is of pyramidal growth with short and slender branches: leaves 4 to 5 inches long: flowers pure white, appearing before the leaves. A desirable early-flowering species.

Magnolia macrophylla (great-leaved magnolia) is a symmetrical-growing variety with wide, spreading branches, growing naturally as far south as Florida: leaves 18 to 24 inches in length, 9 to 10 inches wide, bright green above, silvery beneath: flowers 10 to 12 inches in diameter, white, disagreeable odor. Tree attains a height of 20 to 50 feet.

Magnolia Soulangeana (Soulang's magnolia) is a magnificent tree of garden origin and is supposed to be a hybrid between *Magnolia liliflora* and *Magnolia denudata:* leaves dark green, expanding after the flowers have passed: flowers large, cup-shaped, creamy white, more or less suffused with pink; blooms in March: hardy: ultimate height, 25 feet. Var. *nigra* (dark-flowered magnolia) is a variety of vigorous and robust growth: flowers large, dark purple, several shades darker than *Magnolia liliflora*, a free bloomer; begins to bloom in March and blooms spasmodically during the entire summer. In var. *Lennei* (Lenne's magnolia) the flowers are deep crimson on the outside; blooms a little later than the type. Var. *speciosa* is almost identical in color with the species but more cup-shaped and petals broader.

Magnolia stellata (*M. Halleana*, starry magnolia) is of dwarf habit: flowers semi-double, pure white and very fragrant. Blooms from two to three weeks earlier than any other magnolia; very hardy.

Magnolia tripetala (umbrella magnolia) is a tree 20 to 40 feet high: leaves dark green, light underneath: flowers 8 to 10 inches in diameter, white: leaves 10 to 21 inches long, 6 to 8 inches broad. Found from Pennsylvania to Mississippi.

KEY TO THE SPECIES.

A. *Blossoms appear after or with the lvs.: fr. subglobose to oblong, cone-like, usually symmetrical.*
B. *Foliage deciduous.*
C. *Fls. white, large.*
D. *Base of lvs. cordate.*
E. *Lf.-buds and branches tomentose: lvs. scattered, 20–30 in. long*.................. 1. **macrophylla**
EE. *Lf.-buds and branches glabrous: lvs. crowded at the end of the flowering branchlets, 5–12 in. long.*
F. *Lvs. acute: tips of mature carpels nearly straight*... 2. **Fraseri**
FF. *Lvs. obtusely pointed: tips of mature carpels incurved*................ 3. **pyramidata**
DD. *Base of lvs. narrowed, rarely rounded or subcordate.*
E. *Length of lvs. 5–24 in.; lvs. crowded at the end of the branches: buds and branchlets glabrous.*
F. *Filaments whitish: fr. 2½–4 in. long.*
G. *Fls. 8–10 in. across: lvs. 12–24 in. long*........ 4. **tripetala**
GG. *Fls. 5–6 in. across: lvs. 5–9 in. long*.......... 5. **Thompsoniana**
FF. *Filaments purple: fr. 5–7½ in. long*............ 6. **hypoleuca**
EE. *Length of lvs. 3–7 in.; lvs. scattered.*
F. *Shape of lvs. elliptic-oblong to oblong-lanceolate, 3–5 in. long.*
G. *Under side of lvs. glabrous except the rufous-pubescent midrib*..... 7. **Nicholsoniana**
GG. *Under side densely silky tomentose*....... 8. **Wilsonii**
FF. *Shape of lvs. oval to elliptic, sparingly appressed pubescent beneath or glabrous, 4–7 in. long.*
G. *Peduncles and petioles glabrous or nearly so: fls. short-stalked*...... 9. **Watsonii**
GG. *Peduncles and petioles pubescent: fls. slender-stalked*..............10. **parviflora**
CC. *Fls. greenish or yellow: lvs. 7–10 in. long, sometimes rounded or subcordate at the base*..........11. **acuminata**
BB. *Foliage evergreen (half-evergreen or deciduous N. in No. 12).*
C. *Petals 6–12; fls. upright.*
D. *Lvs. glabrous or silky pubescent beneath.*
E. *Number of petals 9–12: deciduous or half-evergreen.*12. **glauca**
EE. *Number of petals 7 or 8: evergreen trees.*
F. *Length of lvs. 5–7 in., obtusely acuminate: petals 1½ in. long*......13. **splendens**
FF. *Length of lvs. 8–12 in., usually rounded: petals 4 in. long*.............14. **Delavayi**
DD. *Lvs. ferrugineous-pubescent beneath: petals 6–12, 3–5 in. long*.....................15. **grandiflora**
CC. *Petals 6; sepals green; fls. nodding, globular, 1½ in. across*........16. **Coco**
AA. *Blossoms appearing before the lvs. (with the lvs. in No. 19): fr. cylindric, unsymmetrical, usually curved and twisted.*
B. *Sepals 3, narrow and much shorter than petals.*
C. *Fls. white.*
D. *Lvs. oblong-lanceolate or narrow-elliptic, broadest below the middle, membranous*........17. **salicifolia**
DD. *Lvs. obovate to obovate-oblong, broadest above the middle, chartaceous*................18. **Kobus**
CC. *Fls. purple, rarely nearly white.*
D. *Sepals much shorter than petals, green, lanceolate; petals purple outside*.................19. **liliflora**
DD. *Sepals usually half as long as petals, usually petaloid; fls. sometimes nearly white*......20. **Soulangeana**
BB. *Sepals and petals alike.*
C. *Petals 9, usually white: lvs. obovate, 3–6 in. long*..............21. **denudata**
CC. *Petals 9–18.*
D. *Lvs. obovate-oblong, 2–3½ in. long: fls. 3 in. across, usually white*.......................22. **stellata**
DD. *Lvs. elliptic to elliptic-oblong, 5–12 in. long: fls. 6–10 in. across, pink outside* ....23. **Campbellii**

1. **macrophýlla,** Michx. LARGE-LEAVED CUCUMBER TREE. Tree, to 50 ft., with spreading branches: lvs. oblong-obovate, blunt, subcordate-auriculate at the base, glaucescent and finely pubescent beneath, 1–3 ft. long: fls. cup-shaped, fragrant, 10–12 in. across; petals 6, oblong-obovate, thick, purplish at the base, 6–7 in. long: fr. broadly ovate, rose-colored, to 3 in. long. May, June. Ky. to Fla., west to Ark. and La. S.S. 1:7, 8. B.M. 2981. G.F. 8:165. Gn. 22, p. 28; 24, p. 509; 33, p. 539. F.R.S. 1, p. 14. F.E. 14, p. 23. G.C. III. 28:324. Gn. M. 7:230.

2. **Fràseri,** Walt. (*M. auriculàta*, Lam.). Tree, to 40 ft., with wide-spreading branches, quite glabrous: lvs. spatulate-obovate, cordate-auriculate at the base, acute, glaucescent beneath, 8–20 in. long: fls. 6–9 in. across, sweet-scented; petals 6–9, oblong-obovate, contracted below the middle, 4–5 in. long: fr. oblong, bright rose-red, 3–5 in. long. Va. to Fla., west to Miss. S.S. 1:11 and 12. B.M. 1206. Gn. 22 p. 27; 24, p. 511; 44, p. 935. F.E. 33:1071. Gn.M. 5:150. C.L.A. 5:494.

3. **pyramidàta,** Pursh. Slender tree, to 30 ft., with ascending branches, glabrous: lvs. obovate-spatulate, cordate-auriculate at the base, abruptly narrowed into a blunt point, glaucescent beneath, 5½–8½ in. long: fls. 3½–4 in. across; sepals much shorter than petals; petals 6–9, oblong-obovate, gradually narrowed toward the base: fr. oblong, bright rose, 2–2½ in. long. June. Ga. to Fla. and Ala. S.T.S. 1:51. S.M. 324. B.R. 407. L.B.C. 11:1092.

4. **tripétala,** Linn. (*M. Umbrélla*, Lam.). UMBRELLA TREE. Tree, to 40 ft., with spreading branches, forming an open head: lvs. tapering toward the base, oblong-obovate, acute, pale and pubescent beneath when

young, 12–24 in. long: fls. 8–10 in. across, of a disagreeable odor; petals 6–9, oblong-obovate, 4–5 in. long; sepals recurved, light green: fr. rose-colored, ovate-oblong, 2½–4 in. long. May. Pa. to Ala., west to Ark. and Miss. S.S. 1:9, 10. Gn. 22, p. 27; 24, p. 509; 33, p. 539. C.L.A. 5:494.

5. **Thompsoniàna,** Sarg. (*M. glaùca* var. *màjor*, Sims. *M. glaùca* var. *Thompsoniàna,* Loud.). Fig. 2296. Hybrid of *M. glauca* and *M. tripetala.* Shrub or small tree: branches and buds glabrous: lvs. oval to oblong, acute, glaucescent beneath and pubescent when young, 5–9 in. long: fls. white, fragrant, 5–6 in. across; sepals shorter than the petals, yellowish. June, July. G.F. 1:269 (adapted in Fig. 2296). B.M. 2164. Gn. 24, p. 511.—Of garden origin; tenderer than either one of the parents.

6. **hypoleùca,** Sieb. & Zucc. (*M. obovàta*, Thunb.). Fig. 2297. Tree, to 100 ft. high, with broad, pyramidal head: branches purplish: lvs. obovate to obovate-oblong, obtusely pointed, glaucous and appressed pubescent beneath, 8–14 in. long: fls. 6–7 in. across, cup-shaped, fragrant, with 6–9 petals; stamens with purple filaments: fr. oblong-cylindric, scarlet, to 8 in. long. May, June. Japan. G.F. 1:305 (adapted in Fig. 2297). Mn. 3, p. 73. B.M. 8077. F.S.R. 3, p. 251. S.I.F. 1:39. G. 27:659. Gn.M. 5:151. G.W. 3, pp. 85, 87. M.D. 1904:1; 1912, p. 337.—One of the most beautiful of the deciduous species, the under side of the lvs. being almost silvery white; about as hardy as *M. macrophylla.* The name *M. hypoleuca* is used here, instead of the oldest name, *M. obovata,* to avoid confusion, as the latter name has been applied erroneously by most botanists to the plant named here *M. liliflora* (for further remarks on the nomenclature of this and other species, see Sargent, Plant. Wilson. 1:400, 403, 406).

7. **Nicholsoniàna,** Rehd. & Wilson. Shrub or small tree, to 20 ft.: branchlets sparingly pubescent: lvs. slender-petioled, elliptic-oblong to obovate-oblong, acute or short-acuminate, glabrous above, glaucescent beneath and glabrous except the densely rufous-pubescent midrib, 3–5 in. long.: fls. white, cup-shaped, about 4 in. across; sepals and petals usually 12, the inner row shorter; filaments and carpels red: fr. oblong-cylindric, 1⅓–2 in. long. June. W. China.

8. **Wìlsonii,** Rehd. (*M. parviflòra* var. *Wìlsonii*, Finet & Gagnep.). Shrub or small tree, to 20 ft.: branchlets pubescent: lvs. slender-petioled, elliptic-lanceolate, rarely elliptic-ovate, acute or short-acuminate, sometimes subcordate at the base, glabrous above, densely silky tomentose beneath, 3–5 in. long: fls. white, cup-shaped, fragrant, 4–5 in. across; sepals and petals usually 9, of equal size; filaments and carpels red: fr. oblong-cylindric, about 2½ in. long. June. W. China.

2297. Magnolia hypoleuca. (×⅓)

9. **Wàtsonii,** Hook. Closely allied to the former: almost glabrous, except lvs. beneath when young: lvs. obovate to oblong, 4–7 in. long: fls. short-stalked, 5–6 in. across, with 6–9 petals: carpels many. June. Japan. B.M. 7157. G.C. III. 16:189; 17:517. Gt. 48:1459. Gng. 1:8. Gn. 24:508 (as *M. parviflora*) probably belongs here. G.M. 34:305. Gn.M. 5:151. R.B. 31, p. 258. C.L.A. 5:495.—Very handsome in bloom; the beauty of the large, sweet-scented fl. is much heightened by the crimson center, formed by the bright colored stamens.

10. **parviflòra,** Sieb. & Zucc. (*M. Oyàma,* Kort). Small tree: branchlets and buds appressed pubescent: lvs. elliptic to obovate-oblong, obtusely pointed, glaucescent beneath and pubescent at first, 4–6 in. long: fls. long-pedicelled, cup-shaped, white, with large pink sepals, 3–4 in. across, fragrant; petals usually 6; stamens crimson: carpels few. June. Japan. B.M. 7411. Gn. 54, p. 177; 60, p. 81. F.S.R. 2:88. G. 33:373; 36:591. Gng. 1:8; 3:3. G.M. 38:66.

2298. Magnolia glauca. (×¼)

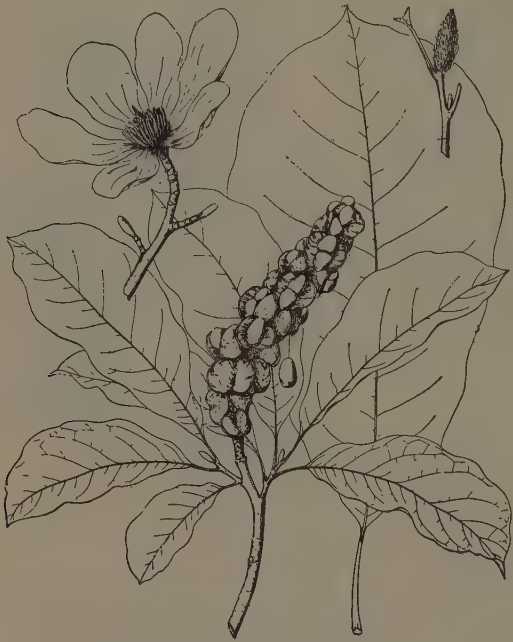
11. **acuminàta,** Linn. Cucumber Tree. Tall, pyramidal tree, to 90 ft.: lvs. oval to oblong, shortly acuminate, rounded or acute at the base, soft pubescent and light green beneath, 6–9 in. long: fls. greenish yellow or glaucous green, about 2–3½ in. high, with upright petals: fr. cylindric, pink, 3–4 in. long. May, June. N. Y. to Ga., west to Ill. and Ark. S.S. 1:4 and 5. B.M. 2427. L.B.C. 5:418. Gn. 24, p. 509. F.E. 20:64 (pl. 102); 32:331. R.H. 1912, p. 427. Var. **cordàta,** Sarg. (*M. cordàta,* Michx.). Lvs. broader, rounded or sometimes cordate at the base: fls. smaller, canary-yellow. S. C., Ala. S.S. 1:6. B.M. 2427. L.B.C. 5:474. Gn. 22, p. 27; 24, p. 509.

12. **glaùca,** Linn. (*M. virginiàna,* Morong). Sweet, Swamp or White Bay. Beaver Tree. Fig. 2298. Attractive shrub or small tree, evergreen S.: lvs. oval to oblong-lanceolate, glaucous beneath and silky-pubescent at first, 3–6 in. long: fls. white, globose, fragrant, 2–3 in. across; sepals nearly as large as petals, spreading; petals 9–12, roundish obovate: fr. pink, 1–2 in. long. May, June. Mass. to Fla. near the coast, in the S. extending west to Texas. S.S. 1:3. Em. 2:603. L.B.C. 3:215. R.H. 1894, p. 347. G.F. 10:403. C.L.A. 5:493. G.W. 14, p. 205. Gng. 4:342. Gn. 78, p. 378.—A very desirable shrub, with handsome, glossy foliage and sweet-scented, creamy white fls. Var. **longifòlia,** Loud., has lanceolate lvs. and continues blooming during a longer time than the type.

13. **spléndens,** Urban. Laurel Sabino. Evergreen tree, to 80 ft.: branchlets appressed-pubescent: lvs. ovate or elliptic-ovate, obtusely acuminate, rounded at the base, glabrous and glossy above, covered with a lustrous silky tomentum beneath, 4–7 in. long: fls. on stalks ¾ in. long; sepals 3, green, obovate-oblong; petals about 8, white, obovate, 1¾ in. long: fr. oval, about

½in. long. June–Aug. Porto Rico.—Suited for tropical and subtropical regions only.

14. **Delavàyi,** Franch. Evergreen shrub or tree, to 30 ft.: branchlets glabrous: lvs. ovate to ovate-oblong, obtuse and usually mucronate, rounded at the base, glabrous above except the midrib, puberulous beneath and pruinose, pubescent on the midrib, 8–13 in. long: fls. creamy white, fragrant; sepals 3, oblong, 3½ in. long; petals about 7, oblong-obovate or spatulate-obovate, 3¼–4¼ in. long: carpels tomentose below: fr. ovoid-oblong, 4¼–5½ in. long. July. W. China. B.M. 8282. G. 35:639.—Probably as hardy as *M. grandiflora.*



2299. Magnolia Kobus var. borealis. (×¼)

15. **grandiflòra,** Linn. (*M. fœtida,* Sarg.). Bull Bay. Tall evergreen tree, to 80 ft., of pyramidal habit: branchlets and buds rusty-pubescent: lvs. thick and firm, oblong to obovate, glossy above, ferrugineous-pubescent beneath, sometimes glabrous at length, 5–8 in. long: fls. white, fragrant, 7–8 in. across; sepals large, petaloid; petals 6–12, obovate; stamens purple: fr. oval or ovate, rusty brown and pubescent, 3–4 in. long. May–Aug. N. C. to Tex. S.S. 1:1, 2. Gn. 22, p. 28; 24, pp. 509, 511; 33, p. 538. J.H. III. 52:237. G. 2:567; 9:225; 19:153; 36:187. G.W. 3, p. 377. F.E. 17:788, p. 781. Var. **angustifòlia,** Loud. (var. *salicifòlia,* Hort.). Lvs. lanceolate, wavy. Var. **lanceolàta,** Ait. Lvs. oblong-lanceolate or oblong-elliptic, less rusty beneath. B.M. 1952. L.B.C. 9:814. There are many other named varieties, as: var. **gloriòsa,** Hort., with fls. to 14 in. across and broad lvs.; var. **rotundifòlia,** Hort., with very dark green roundish lvs.; var. **prǽcox,** Hort., early-flowering; var. **obovàta,** Nichols., with obovate-oblong lvs.; var. **Kathariniàna,** Bedelian, with very broad lvs. and smaller fls. with narrower petals; var. **galissoniénsis,** Hort., one of the hardiest forms; var. **Pravertiàna,** Hort., of stubby pyramidal habit; var. **exoniénsis,** Loud. (var. *strícta,* Hort. *M. oxoniénsis,* Hort.), of vigorous growth and narrow pyramidal habit: lvs. oblong-elliptic, usually rusty beneath: fls. somewhat contracted. Blooms early and freely.

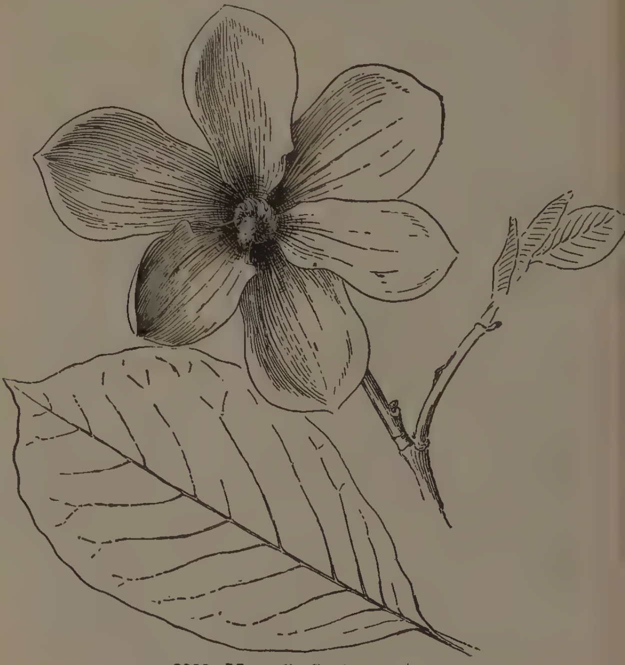
16. **Còco,** DC. (*M. pùmila,* Andr. *Talaùma pùmila,* Blume). Shrub, to 12 ft.: lvs. elliptic-oblong, acuminate, glabrous, glaucescent beneath, 3–6 in. long: fls. axillary, nodding on short-curved pedicels, globose-ovate, white, fragrant, about 1¼ in. across; petals 6. China. B.M. 977. G.W. 14, p. 220.—Cult. S.

17. **salicifòlia,** Maxim. Slender tree, to 20 ft.: branchlets and buds glabrous: lvs. elliptic-ovate to ovate-lanceolate, acuminate, sometimes bluntly so, broadly cuneate at the base, yellowish green above, glaucescent beneath, glabrous, 3–6 in. long: fls. short-stalked, about 5 in. across, white; sepals lanceolate, greenish white, half as long as petals; petals 6, narrowly oblong-obovate, 2–2½ in. long: fr. cylindric, 1½–3 in. long. April. Japan. B.M. 8483. G.C. III. 51:223. G.F. 6:67. S.I.F. 1:40. M.D.G. 1910:542, 543. Gn. 78, p. 196.

18. **Kòbus,** Thunb. (*M. Thúrberi,* Hort.). Tree, to 80 ft., with narrow pyramidal head: branchlets glabrous, slender: lvs. broadly obovate, abruptly pointed, tapering toward the base, pubescent below at first, 3½–6 in. long: fls. 4–5 in. across; sepals very small and narrow; petals 6, spreading, thin, 2–2½ in. long: fr. slender, dark brown, 4–5 in. long. April, May. Japan. B.M. 8428. G.C. III. 37:264. S.I.F. 1:39. M.D.G. 1902:529. S.T.S. 2:126. —One of the hardiest species but less showy; seems not to flower very profusely. Var. **boreàlis,** Sarg. Fig. 2299. Larger lvs., fls. and frs. than the type. G.F. 6:66 (adapted in Fig. 2299).

19. **liliflòra,** Desrouss. (*M. obovàta,* Willd., not Thunb. *M. díscolor,* Vent. *M. purpùrea,* Curt. *M. denudàta,* Schneid., not Desrouss.). Usually large shrub, with stout branches: lvs. obovate or oval-obovate, acute or acuminate, pubescent beneath at first, 4–7 in. long: fls. large, campanulate, white inside, purple outside, scentless; petals broad, obtuse, somewhat fleshy, about 3½ in. long; sepals small, ovate-lanceolate, greenish yellow: fr. brownish, ovate-oblong. May, June. China, Japan. B.M. 390. Gn. 22, p. 485; 24, p. 511; 46, p. 49. F.E. 9:611; 17:528 (pl. 74). Var. **grácilis,** Rehd. (*M. grácilis,* Salisb.). Smaller shrub, with slender branches, narrower lvs. and smaller fls., dark purple outside. Var. **nìgra,** Rehd. (*M. Soulangeàna* var. *nìgra,* Nichols.). Fls. dark purple outside, pink inside (Gn. 25:276).

20. **Soulangeàna,** Soul. (*M. denudàta* × *M. liliflòra*). Fig. 2300. Intermediate between the parents. Popular



2300. Magnolia Soulangeana. (×¼)

large shrub or small tree: lvs. obovate to obovate-oblong: fls. large, campanulate, white, more or less purplish outside, often fragrant; sepals usually colored, sometimes almost as long, sometimes hardly half as long as petals, rarely small and greenish. May. A.G. 15:283. B.R. 1164. Gn. 59, p. 241; 66, p. 76; 76, p. 135. F.R. 8:3. R.H. 1912, p. 373. F.E. 15:482 (pl. 51). Gt. 5:166 and 168. Var. **Lennéi,** Rehd. Nearer to *M. liliflora.* More shrubby: fls. large, deep crimson outside, late. F. 1864:25. V. 5:196. G. 26:316. G.M. 53:1031. G.L. 24:7. Var. **Niemétzii,** Hort. A fastigiate form.

There are many other named varieties, varying in color and flowering-time, as var. **Alexandrìna,** Hort., fls. outside toward the base deep purple, white inside, one of the earliest (Gn. M. 5:149. R.B. 26:217. R.H. 1912, p. 370); var. **álba supérba,** Hort., white (G. 33:449); var. **Brozzònii,** Hort., fls. white, shaded purple (G. 34:429, 431); var. **cyathifórmis,** Hort. Rinz., cup-shaped, light purple; var. **grándis,** Hort. Rinz., white, outer petals purple at base and in the middle; var. **Norbertiàna,** Hort., white and light purple, one of the latest to bloom; var. **rústica** (*M. rústica fl. rùbro,* Hort.), deep purple outside (F.S.R. 1:16. G. 29:201); var. **speciòsa,** Hort., white, striped purple outside; var. **triúmphans,** Hort., pink toward the base outside. These hybrids are among the most popular magnolias on account of their early, bright-colored fls.: they are showier and hardier than the preceding species.

21. **denudàta,** Desrouss. (*M. précia,* Correa. *M. conspícua,* Salisb. *M. Yùlan,* Desf.). Fig. 2301. Tree, to 50 ft., with spreading branches: lvs. obovate or obovate-oblong, shortly pointed, pubescent beneath when young, 4–7 in. long: fls. large, campanulate, white, sweet-scented, about 6 in. across; petals and sepals almost alike, 9, concave, fleshy, 3–4 in. long: fr. brownish, 3–4 in. long, slender. April, May. Cent. China. B.M. 1621. L.B.C. 12:1187. G.C. III. 9:591.; 36:59. Gn. 21, p. 311; 23, p. 138; 24, p. 511; 31, p. 505; 34:667; 45, p. 365; 46, p. 145; 51, p. 474. G.M. 31:289; 36:386; 44:181. G. 26:47. C.L.A. 3:173. M.D.G. 20:253. G.W. 14, p. 206.—One of the most showy species. Var. **purpuráscens,** Rehd. & Wilson (*M. conspícua* var. *purpuráscens,* Maxim.). Fls. rose-red outside, pale pink within. Var. **elongàta,** Rehd. & Wilson. Lvs. longer and larger: fls. larger, white.

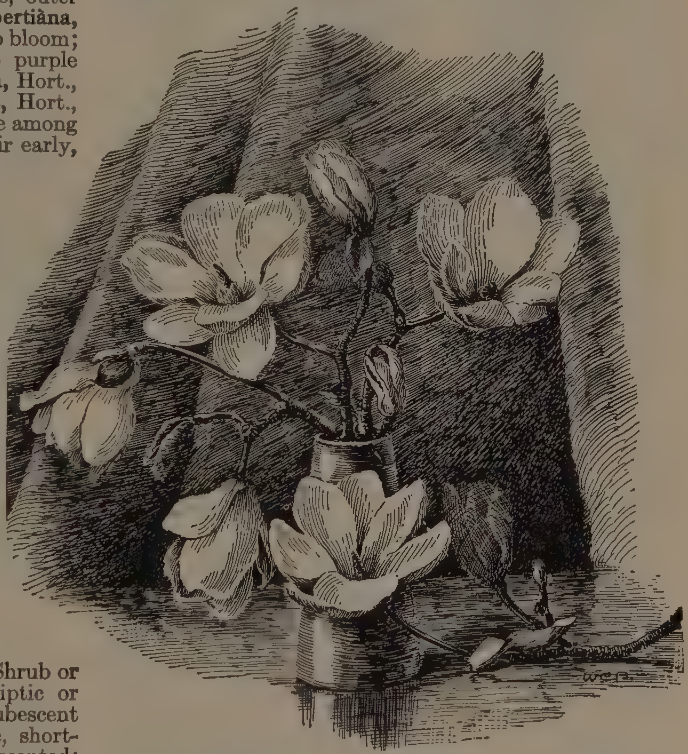
22. **stellàta,** Maxim. (*M. Halleàna,* Hort.). Shrub or small tree, with spreading branches: lvs. elliptic or obovate to oblong-obovate, obtusely pointed, pubescent beneath when young, 2–5 in. long: fls. white, short-stalked, numerous, about 3 in. across, sweet-scented; petals narrow-oblong, 9–18, spreading and afterward reflexed: fr. with only few fertile carpels. March, April. Japan. B.M. 6370. R.H. 1878:270. Gn. 13:572; 61, p. 379; 75, p. 240; 77, p. 145; 78, p. 117. G.F. 9:195. G.C. III. 7:617; 17:521; 39:260, 261. Gng. 2:57. A.F. 6:305. F.E. 9:611; 15, pl. 318, 616 (pl. 53). G.M. 38:489; 44:180; 50:293; 57:769. Gn.M. 3:267; 5:141, 150. Gn.W. 20:15. Gt. 52, p. 409. M.D.G. 1909:289. G.W. 5, p. 113; 14, p. 207. F.M. 1878:309.—Quite hardy and very free-flowering; it begins to flower when hardly 2 ft. high. Var. **ròsea,** Hort. Fls. blushed outside. R.B. 30, p. 85. J.H.S. 27, p. 865. Var. **Keìskei,** Makino. Densely branched shrub: fls. smaller, purple outside. Not yet intro.

23. **Cámpbellii,** Hook. f. & Thoms. Tree, to 80 ft.: lvs. elliptic-oblong or ovate, abruptly acuminate, glaucous beneath and silky pubescent when young, 5–12 in. long: fls. cup-shaped, 6–10 in. across, white and pink inside, shaded with crimson outside; petals obovate, 9–15: fr. greenish brown, 6–8 in. long. May. Himalayas. B.M. 6793. F.S. 12:1282–5. Gn. 48:142; 53, pp. 167, 305. G.C. III. 23:89; 42:4. F.S.R. 2:296. G. 35:175. Gn.W. 23:552. J.H. III. 42:117; 62:145.—Beautiful tree, hardy only S.

M. compréssa, Maxim.=Michelia compressa.—*M. Dawsoniàna,* Rehd. & Wilson. Tree, to 35 ft.: lvs. subcoriaceous, obovate, glossy above, glabrous beneath, 3–6 in. long: fr. cylindric, 4 in. long: fls. unknown. W. China.—*M. fuscàta,* Andr.=Michelia fuscata.—*M. globòsa,* Hook. f. & Thoms. Allied to M. parviflora. Tree, to 40 ft.: lvs. ovate, fulvous-pubescent on the veins beneath, 5–9 in. long: stamens and pistil bright red: fr. oblong, 2 in. long. Himalayas.—*M. officinàlis,* Rehd. & Wilson. Closely related to M. hypoleuca. Branchlets yellowish: lvs. obovate, to 1½ ft. long: stamens shorter: fr. oblong-ovate, 4–5 in. long. Cent. China.—*M. Sargentiàna,* Rehd. & Wilson. Tree, to 75 ft.: lvs. subcoriaceous, obovate, glabrous above, pubescent beneath, 4–7½ in. long: fr. cylindric, 4–6 in. long: fls. unknown, said to be rosy red and about 8 in. across. W. China. Var. *robústa,* Rehd. & Wilson. Lvs. oblong-obovate, 6–9 in. long: fr. to 7½ in. long.

Alfred Rehder.

MAGYDÀRIS (old Greek name). *Umbelliferæ.* Two perennial herbs of Spain, Sicily and N. W. Afr., one of which is offered abroad as an ornamental plant. Lvs. pinnate or pinnatisect, the segms. large, dentate or cut: fls. white in compound many-rayed umbels, with the many bracts of the involucre and involucels linear or lanceolate; petals obovate and inflexed at the apex and more or less 2-lobed: fr. oblong, tomentose. **M. tomentòsa,** Koch, has lvs. pinnatisect, tomentose beneath, nearly or quite glabrous above: bracts of involucre elongated-linear and undivided: fr. ovate, the carpels very obtuse and tomentose.



2301. Magnolia denudata, commonly known as M. conspicua.

MAHÉRNIA (anagram of *Hermannia*). *Sterculiàceæ.* One very fragrant herb-like plant in greenhouses, and perhaps one or two others are cultivated. By some united with Hermannia.

Calyx campanulate, 5-cleft; petals 5, with hollow claws, twisted in the bud; stamens 5, opposite the petals, the filaments prominently enlarged or dilated at about the middle (and thus differing from Hermannia, which has no sudden enlargement in the filaments), the anthers long; ovary 5-loculed, ripening into a coriaceous caps. with many seeds.—More than 30 herbs and subshrubs of S. Afr., mostly with incised lvs. and drooping, bell-shaped fls.

verticillàta, Linn. (*M. odoràta,* Hort., not of botanists, which is *Hermannia Presliana*). Honey-Bell. Fig. 2302. A frequent plant in conservatories, and sometimes seen in window-gardens and collections: half woody, very diffuse and straggly, not making a central leader, the terete crooked sts. scabrous: lvs. small, much cut into linear divisions, with deep-cut stipules: fls. ¾in. or less long, nodding, usually about 2 together, from axillary shoots, sweet, fragrant, honey-yellow.—Free bloomer in winter and spring. Of easy cult. Prop. by cuttings. A very pretty twiggy bush for the cool greenhouse. The branches are long and flexible, so that specimens may be trained into any form. It may also be used for hanging-baskets. It is of easy cult. in pots, but lifts badly.

2302. Mahernia verticillata. (×⅔)

glabràta, Cav. Lvs. dentate or dentate-pinnatifid (not so finely cut as in the last), covered with stellate down: trailing, not odorous.—It is doubtful whether the plant cult. under this name is the *M. glabrata* of botanists.

L. H. B.

MAHOE, MOUNTAIN: *Hibiscus elatus.*

MAHOGANY: *Swietenia.* **Mountain M.:** *Cercocarpus.*

MAHÒNIA (after Bernard M'Mahon, a prominent American horticulturist; 1775–1816; see Vol. III, p. 1586, for a biographical sketch). Syn., *Odostèmon. Berberidàceæ.* Ornamental woody plants grown chiefly for their handsome evergreen foliage and for their large panicles of yellow flowers. Usually united with Berberis.

Evergreen shrubs, rarely small trees: lvs. alternate, odd-pinnate, rarely 3-foliolate, with minute subulate stipules: fls. yellow, in many-fld. racemes or panicles springing from the axils of bud-scales; sepals 9; petals 6 with nectaries at the base; stamens 6; ovary 1-celled with usually few ovules: fr. a dark blue and bloomy, rarely red berry, with usually few small seeds.—About 45 species in N. and Cent. Amer. and E. and S. E. Asia. From Berberis with which it is often united, it is easily distinguished by the pinnate lvs. and the unarmed branches, also by the large infl. springing from the axils of bud-scales and by the 9 sepals. Monograph by Fedde in Engler, Bot. Jahrbücher 31:30–133 (1901).

The mahonias are very handsome evergreen shrubs spreading usually by suckers, with large leaves and yellow flowers in conspicuous panicles appearing in spring and followed by dark blue bloomy berries. Most of the species are tender, but *M. repens, M. Aquifolium, M. nervosa, M. pinnata* var. *Wagneri* are hardy as far north as Massachusetts, but the foliage is liable to be scorched if exposed to the winter's sun, though *M. repens* is more resistant and is rarely burned. *M. japonica* will succeed if planted in sheltered situations. *M. pinnata* is a most beautiful evergreen species, but it requires protection from cold winds, and the winter's sun. *M. repens* is the best evergreen species we have. It spreads rapidly and the foliage is rarely burned, and the numerous clusters of showy yellow flowers render it most attractive at the end of May. They prefer a humid soil and a position sheltered from strong winds and from the hot sun. They are easily transplanted and some, particularly *M. repens* and *M. nervosa,* spread considerably by suckers. Propagation is by seeds sown soon after maturity or stratified and sown in spring, or by suckers which are freely produced in most species, also by cuttings of half-ripened wood under glass and by layers.

pinnata, 3.
repens, 2.
rotundifolia, 2.
trifurca, 6.
Wagneri, 3.

A. *Racemes many-fld., usually dense.*

B. *Lfts. rounded or truncate at the base, rarely cuneate, ovate to ovate-oblong.*

C. *Texture of lvs. leathery; lfts. 3–9, sometimes 13.*

D. *Petiole about 1 in. long; lfts. 3–9.*

1. **Aquifòlium,** Nutt. (*Bérberis Aquifòlium,* Pursh. *Odostèmon nutkànus,* Rydb.). Fig. 2303. From 3–6 ft.: lfts. 5–9, oblong or oblong-ovate, dark green and lustrous above, spinulose-dentate, 1½–3 in. long: racemes erect, fascicled: berries blue, small. May. Brit. Col. to Ore. B.R. 1425. L.B.C. 18:1718. P.M. 9:5. G. 12:721; 28:143. G.M. 44.659. Gn.W. 23:361. Var. **juglandifòlia,** Jouin. Lfts. usually 7, the lowest pair usually close to the base of the petiole, often subcordate at the base, smaller and of thicker texture, teeth smaller, accumbent; rachis usually red. Var. **grácilis,** Jouin (*M. grácilis,* Hort., not Fedde). Lfts. 5–9, oblong-ovate, cuneate at the base, spinose-serrate with small teeth, slightly lustrous above, 2–3 in. long. There are also forms with variegated lvs., with yellow foliage and with the young foliage bright red.

2. **rèpens,** Don (*Bérberis rèpens,* Lindl. *B. Aquifòlium,* Brit. & Brown. *B. nàna,* Greene. *Odostèmon Aquifòlium,* Rydb.). Rarely over 1 ft. high, stoloniferous: lfts. 3–7, roundish ovate or ovate, pale or glaucous and dull above, spinulose-dentate, 1½–2½ in. long: fls. and fr. as in the preceding. Brit. Col. to Calif. and N. Mex. B.R. 1176. L.B.C. 19:1847.—Hardier than the preceding species, but less handsome. Var. **rotundifòlia,** Fedde (*Bérberis rotundifòlia Hèrveyi,* Hort.). Lfts. usually 5, broader, often suborbicular, nearly entire or finely and sparingly serrate. Var. **macrocárpa,** Jouin. Frs. thicker and lvs. less opaque.

2303. Mahonia Aquifolium. (×⅓)

DD. *Petiole usually very short; lfts. 7–13.*

3. **pinnàta,** Fedde (*Bérberis pinnàta,* Lag. *M. fasciculàris,* DC. *B. Aquifòlium* var. *fasciculàris,* Bean). Two to 6 ft.: lfts. 7–13, ovate or ovate-lanceolate, undulate at the margin and with few spiny teeth,

grayish green and somewhat lustrous above, 1–2½ in. long: fls. in short, fascicled racemes: fr. blue. Calif., N. Mex. and Mex. B.M. 2396. B.R. 702. Var. **Wágneri,** Jouin. Lfts. 7–11 with 4–5 teeth on each side, dark green above and slightly lustrous, light green beneath. M.D. 1910, p. 89.—This variety is about as hardy as *M. Aquifolium,* but grows taller and is very desirable. Possibly a hybrid with *M. Aquifolium.*

cc. *Texture of lvs. rigid; lfts. 9–25.*

d. *Sts. scarcely exceeding 1 ft.*

4. **nervòsa,** Nutt. (*Bérberis nervòsa,* Pursh. *M. glumàcea,* DC.). Dwarf shrub: sts. with long pointed, husk-like bud-scales: lvs. on stalks 1–4 in. long; lfts. 9–19, lance-ovate, remotely spiny-toothed, 3–5-ribbed, pale green, 1–3 in. long: racemes elongated, erect: fr. oblong, blue. Brit. Col. to Calif. B.M. 3949. L.B.C. 18:1701. B.R. 1426. P.M. 7:55.

dd. *Sts. 5–12 ft. tall: lvs. very short-stalked.*

5. **nepalénsis,** DC. (*Bérberis nepalénsis,* Spreng.). Lfts. 5–25, ovate-oblong, all of nearly equal size, cuneate or rounded at the base, sinuately toothed, with few spiny teeth, lustrous above, 2–4 in. long: racemes to 10 in. long. India, chiefly Himalayas. Gn. 63, p. 94. A.G. 18:355.

6. **japónica,** DC. (*Bérberis japónica,* Spreng. *B. Beàlii,* Fort.). Lfts. 9–13, roundish or ovate, the terminal one larger, usually truncate or subcordate at the base, with large remote spiny teeth, dull or slightly lustrous above, 2–5 in. long: racemes 3–4 in. long, fascicled: fr. bluish black. China, Himalayas, in Japan only cult. B.M. 4846, 4852. Gn. 63, p. 72. F.S. 6:79. Gn.M. 2:19. H.F. 5:168. G. 2:299; 29:341 and J.F. 3:278 (as *B. nepalensis*).—Very effective by its large bold foliage; has proved hardy at the Arnold Arboretum in sheltered positions. Var. **trifùrca,** Schneid. (*B. trifùrca,* Forbes). Lfts. 4 in. long and 2 in. broad, 3-pointed at the apex and with a few teeth at the base. Var. **gracíllima,** Fedde. Lfts. smaller, about 2 in. long and ¾ in. broad.

bb. *Lfts. cuneate at the base, lanceolate.*

7. **Fórtunei,** Fedde (*Bérberis Fórtunei,* Lindl.). Shrub, to 6 ft.: lfts. 5–9, narrow-lanceolate, spinose-serrate with small appressed teeth, 2–5 in. long: racemes erect, fascicled, to 6 in. long. China. F.S. 3:291*b*. J.H.S. 1846:300.

aa. *Racemes few-fld.: lfts. rigid, 3–7.*

8. **Fremóntii,** Fedde (*Bérberis Fremóntii,* Torr.). Fig. 2304. Shrub, 5–12 ft.: lfts. 3–7, ovate or oblong, with few strong, spiny teeth, blue-green, dull, ½–1 in. long: racemes loose, 3–7-fld.; pedicels slender: fr. at least ½ in. across, inflated and rather dry, blue. W. Texas to Utah, Ariz. and Calif. G.F. 1:497 (adapted in Fig. 2304).

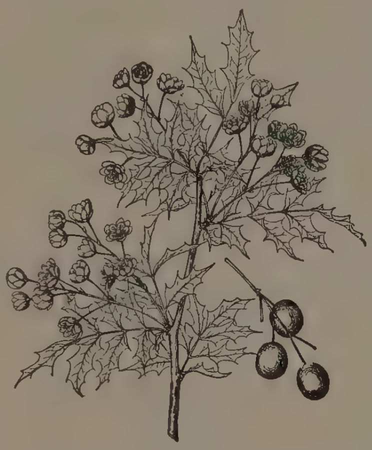
M. argùta, Hutchins. (Berberis Hutchinsonii, Rehd. B. arguta, Ball, not Schneid.). Shrub, to 5 ft.: lfts. 9–11, lanceolate, entire or with few teeth: fls. in pendulous racemes, 12–16 in. long. Probably from Cent. Amer. B.M. 8266. Gn. 72, p. 481.—*M. brévipes,* Rehd. (Berberis brevipes, Greene). Allied to B. repens, but much smaller in every part: lvs. short-petioled; lfts. usually 7, broadly elliptic-oblong, 1–1¾ in. long: racemes short, few-fld. Alberta.—*M. grácilis,* Fedde (Berberis gracilis, Hartw.). Allied to B. pinnata. Lfts. ovate to lanceolate, finely serrate or entire, 1–2 in. long, lustrous. Mex., Texas.—*M. hæmatocárpa,* Fedde (Berberis hæmatocarpa, Wooton). Very similar to B. Fremontii, but the terminal lft. longer than the lanceolate lateral ones: fr. red. Colo. and New Mex.—*M. heterophýlla,* Schneid. (B. heterophylla, Zabel, not Juss. B. toluacensis, Hort.). Possibly M. Aquifolium ×M. Fortunei. Lvs. long-petioled; lfts. 5–7, lanceolate, 1½–3½ in. long, ⅓–1 in. broad, spiny-toothed, lustrous. Of unknown origin.—*M. pállida,* Fedde (Berberis pallida, Benth.). Lfts. 9–13, ovate to ovate-lanceolate, 2–3½ in. long, spinose, dark green above, grayish beneath: racemes compound, loose. Mex. R.B. 30:16.—*M. pùmila,* Fedde (Berberis pumila, Greene). Allied to M. repens. A foot high or less: sts. upright, rigid, not sarmentose: lfts. 1–5, thick, ovate to round-ovate, coarsely spiny-toothed, reticulate: racemes short: berries smaller, very glaucous. Calif., Coast Range.—*M. tenuifòlia,* Fedde (Berberis tenuifolia, Lindl.). Lfts. 3–7, lanceolate, entire: racemes nodding, very long and loose. Mex. B.R. 30:26.—*M. trifoliolàta,* Fedde (Berberis trifoliolata, Moric. B. trifoliata, Hartw.). Allied to B. Fremontii. Lfts. 3, sessile, rigid, pale; coarsely spiny-toothed: racemes short, few-fld. Texas to Mex. B.R. 31:10. F.S. 1:56.—*M. Wilcoxii,* Rehd. (B. Wilcoxii, Kearny. Odostemon Wilcoxii, Heller). Allied to M. Aquifolium, but lfts. smaller, very coriaceous, oval or ovate with only 3–5 spreading spiny teeth on each side. Ariz.

Alfred Rehder.

MAIÁNTHEMUM (Greek, *Mayflower*). Syn. *Unifòlium. Liliàceæ.* Small spring-blooming woodsy perennials, good for colonizing.

Convallaria-like, with slender rootstocks and 1–3-lvd. sts. that are 3–8 in. or more high and bear a few white 4-parted small fls. in a raceme; segms. separate or practically so, spreading or reflexed, deciduous; stamens 4, inserted at base of segms; ovary 1; style 1. 2-lobed: fr. a globular 2-celled and 1–2-seeded berry.—Species 2 (by some considered only 1), in the cool parts of northern hemisphere. They make interesting mats or colonies in shady places. *M. canadénse,* Desf. (*Unifòlium canadénse,* Greene), native in moist cool woods from Newfoundland to N. C. and west, usually has 2 (1–3) ovate or ovate-lanceolate sessile or very short-petioled lvs. on the st. and many radical lvs. in the spreading colony, cordate at base with narrow sinus: raceme 1–2 in. long, usually many-fld., rather dense; fls. white, the segms. longer than the stamens: berry pale red, speckled: foliage dies in summer. *M. bifòlium,* DC. (*M. Convallària,* Web.) is the European and Asiatic species: lvs. 2, stalked, triangular-cordate: st. 6–8 in. high from a filiform root: raceme spike-like. Var. *kamtscháticum,* Jepson, Calif. to Alaska and Siberia, is 4–14 in. high, often stout: lvs. ovate or triangular-cordate, the petiole of the lower one sometimes longer than the blade, the radical lf. very long-petioled and almost as tall as fl.-st.

L. H. B.



2304. Mahonia Fremontii. (×⅓)

MAIDENHAIR FERN: *Adiantum.*

MAIDENHAIR TREE: *Ginkgo.*

MAIZE: *Corn* and *Zea.*

MAKART DECORATIONS and bouquets are dried grasses and everlastings, whether dyed or not. The celebrated painter, Hans Makart, once decorated his salon with dried palm leaves, pampas grass and the like, to the delight of the Emperor of Austria, who visited the artist's studio; hence the name. See *Everlastings* and G.C. III. 6:714.

MALACOCÁRPUS (Greek, *soft* and *fruit*). *Cactàceæ.* A genus commonly combined with Echinocactus. As usually understood, it consists of globose plants: fls. slightly funnel-shape, usually yellow; ovary with scales bearing in their axils bristles and wool; stigma-lobes red: fr. soft, rose-colored or crimson. Six species have been assigned to this genus; but if it is to be retained, more species are doubtless to be referred to it. It is native of the east coast of S. Amer. **M. Sellòwii,** Schum., is offered in the European trade under the name of *Echinocactus Sellowii.*

J. N. Rose.

MALACÓTHRIX (Greek words, meaning *soft hair*). *Compósitæ.* Annual and perennial herbs of W. N. Amer., one of which is listed; species probably 20: leafy-stemmed or scapose, usually with a radical cluster of lvs.: heads yellow, white or pinkish, peduncled, usually nodding in bud; receptacle naked or bristly; fls. all ligulate, hermaphrodite: achene short, terete, ribbed, with soft pappus-bristles. **M. califórnica,** DC. Annual, acaulescent, bearing single rather large light yellow heads on scapes 4–6 in. high: lvs. prominently woolly when young, pinnatifid, the lobes linear to almost filiform: involucre-bracts narrow-linear or subulate, in about 3 series. Sandy soils, Calif.

L. H. B.

MALAY APPLE: *Eugenia Jambos.*

MALCÒMIA (Wm. Malcolm, English horticulturist of the eighteenth century). Also written *Malcolmia,* but it was originally spelled Malcomia. *Cruciferæ.* Flower-garden annuals.

Malcomia is a genus of branching herbs, the branches often prostrate: lvs. alternate, entire or pinnatifid: fls. white, purplish or reddish, in a loose raceme; petals long and linear or long-clawed: pods rather terete, long or awl-shaped; seeds in 1 series or in 2 series at the base of the cells, not marginate.—Species about 30, Medit. region.

marítima, R. Br. VIRGINIAN STOCK. MAHON STOCK. Figs. 2305, 2306. St. erect, branching: lvs. elliptic, obtuse, entire, narrowed at the base, pubescence appressed, 2–4-parted: pedicels rather shorter than the calyx; fls. shades of lilac and red to white, the limb veined: pods pubescent, long-acuminate at the apex. Medit. region. B.M. 166 (as *Cheiranthus maritimus,* showing red fls., changing to purple before fading). J.H. III. 59:30.—It is a charming hardy annual of the easiest cult. growing about a foot high, with a more branching and open habit than the common stock (Matthiola), and 4-petaled fls. each about ¾in. across. Red, white and crimson-fld. kinds are offered in Amer., while rose and lilac fls. appear in the mixtures. There seem to be no double forms. It is an excellent plant for the front of a border, as it may be easily had in bloom from spring to fall by means of successional sowings. Seeds are best sown in the fall, as they give earlier bloom. Seeds may be sown thinly.

2305. Malcomia maritima.—Virginian stock, Crimson King.

M. bícolor, Boiss. & Heldr. Low, about 6 in., pubescent: lvs. oblong-lanceolate to ovate, nearly entire: fls. pink, yellowish at base. Mountains, Greece. Gt. 1:226.—*M. littòrea,* R. Br. Six to 12 in.: lvs. hoary, lance-linear, nearly entire: fls. large, pink-purple, the spreading limb not prominently veined. W. Medit. region.

WILHELM MILLER.
L. H. B.†

MALLÒTUS (Greek, *woolly,* from the long white spines on the fruit of some species). *Euphorbiàceæ.* Trees or shrubs, some rarely cultivated for their economic products, but very little known as horticultural subjects.

Leaves alternate or in a few species opposite, broad, simple, palmately nerved: fls. diœcious, small, in spikes or panicles; calyx valvate or imbricate; no petals, disk or rudiment of ovary in the staminate fls.; stamens numerous, anther-cells oblong; the 3 styles almost free at base, elongated; ovules 1 in each cell: caps. separating into 2–3 parts.—About 80–90 species in the Old World tropics. Related to Mercurialis and Macaranga.

japónicus, Muell. Arg. (*Rottlèra japónica,* Spreng.). A small, rather scurfy tree with large, ovate, alternate, glabrous or glandular, subtrilobed, reddish lvs.: spikes branched, terminal; fls. 2–3 lines wide; stamens 60–70: caps. ½in. diam., pubescent with weak prickles. Japan and China. R.H. 1894, p. 103.

philippinénsis, Muell. Arg. MONKEY-FACE TREE. KAMILA TREE. Lvs. broadly ovate, rough, entire or nearly so, alternate: caps. not prickly but covered with red-brown glands which furnish the kamila (or kamala) dye of commerce, used in dyeing silks. India to Austral.

J. B. S. NORTON.

2306. Malcomia maritima. (×¾)

MALLOW: *Malva rotundifolia,* and other species.

MALLOW, FALSE: *Malvastrum.*

MALÒPE (name used by Pliny for some kind of mallow). *Malvàceæ.* Flower-garden annuals.

Glabrous or pilose herbs, with entire or 3-parted alternate lvs., and peduncled often showy violet or pink or white axillary fls. subtended by 3 large cordate distinct bracts: calyx 5-parted; column of stamens divided at the top into many filaments: carpels numerous, 1-seeded, congested into a head, indehiscent.—About a dozen species have been described, probably reducible to 3, in the Medit. region. They are of simple cult. in any ordinary garden soil; sow early.

trífida, Cav. Fig. 2307. Plant 2–3 ft. high, bearing rose and purple fls. 2–3 in. across, the center usually darker, blooming most of the summer: lvs. 3-nerved, 3-lobed, dentate, glabrous; lobes acuminate: peduncles axillary, 1-fld. Spain, N. Afr. Gn.W. 25:584. H.U. 2:166. Var. **grandiflòra,** Paxt. (*M. grandiflòra,* F. G. Dietr.), is said to be superior to the type, with fls. large, deep rosy red, veined inside darker. Gn. 21, p. 145. P.M. 1:177. G.W. 15, p. 215. Var. **álba,** Hort., has white fls. Var. **ròsea,** Hort., has rose-colored fls. G. 27:563. Seeds are offered separately in white, rose and red.

malacoìdes, Linn. An old garden annual, but apparently not now cult. to any extent: 1–3 ft.: lvs. oblong-ovate to lanceolate, crenate or pinnatifid, tapering or cordate at base: fls. large, purple-violet, solitary. Var. **ròsea,** Hort., has rose-red fls. S. Eu., Asia Minor.

L. H. B.

MALORTÌEA (E. von Malortie, Germany). *Palmàceæ.* A small group of diminutive palms of Cent. Amer., by some authorities referred to Reinhardtia as a subgenus, with 6–12 stamens. They are spineless plants, with alternate lvs. which are simple or 2-lobed at the end, margins entire or dentate or erose on the ends: fls. unisexual, in branched spadices or spikes that arise from the lower axils. They are warmhouse subjects, and useful where very small palms are desired, as in a Wardian case.

M. grácilis, Wendl. Sts. slender, ringed, 18–24 in. or more high: lvs. slender-petioled, about 9 in. long and broad, split to the rachis at the top, and the 2 halves lobed, the lobes entire or notched, split near the rachis to form holes: spadix erect, branched, bearing scattered sessile male and female fls.; stamens 10–12. Guatemala. B.M. 5291. *M. símplex*, Wendl. Slender cespitose little palm, with oval slender-petioled mostly simple lvs. which are acuminate-toothed and more or less shallow-notched at the apex: spadix few-branched, with sessile fls. Costa Rica. B.M. 5247.—*M. Tuérckheimii*, Damm. Height about 16 in., the sts. thin and about 1½ lines thick and bearing a crown of about 15 geonoma-like dull green lvs.: lf.-blade cuneiform, 6 in. long and 2 in. broad, not bifid, with 19 veins either side of midrib and the blade somewhat folded between them, the margin crenulate; petiole about 1 in. long. Guatemala, 4,500 ft. altitude. G. W. 12, p. 99.—Recent.

L. H. B.

2307. Malope trifida. (×¼)

MALPÍGHIA (Marcello Malpighi, 1628–1693, distinguished naturalist at Bologna, who wrote on the anatomy of plants). *Malpighiàceæ.* Trees and shrubs, sometimes grown under glass for ornament, but known mostly from the Barbados cherry, cultivated in the American tropics.

Leaves opposite, short-stalked, glabrous or tomentose, entire or spiny-toothed: fls. axillary and terminal, clustered or corymbose, rarely solitary, red, rose or white; calyx with a pair of thick glands on the back of some or all the 5 sepals; stamens 10, all perfect, the base of filaments glabrous; ovary 3-celled; styles 3, distinct: drupe 3-pyrenous, not winged, the stones with 3–5 crests or wings on the back.—Species 30–40 in Trop. Amer., extending as far north as S. Texas. Small describes 29 species in N. Amer. Fl. XXV, p. 152 (1910).

glàbra, Linn. Barbados Cherry. Fig. 2308. Shrub, 6 ft., glabrous, the branches slender: lvs. ovate to elliptic, entire, usually pointed, having a few biscuspidate hairs which disappear early: umbels 3–5-fld.; fls. ¾in. across, rose-red, the petals erose or fringed: drupes red or scarlet, about the size of a cherry, acid, with thin skin, used for jam and preserves; seeds large, 4-angled. S. Texas to N. S. Amer.; W. Indies. B.M. 813.—Widely planted in tropics, and offered in S. Fla. Prop. by cuttings, and seeds germinate readily.

mexicàna, Juss. (*M. guadalajarénsis*, Rose). Lvs. ovate to obovate-lanceolate, either acute or obtuse, pubescent or tomentose: cymes one-third to one-half length of lvs.; fls. purplish, about ¾in. across; sepals ovate to ovate-lanceolate, densely pubescent: fr. nearly globose, red. Mex.—Offered in S. Calif.

coccígera, Linn. Lvs. oval or ovate to suborbicular, obtuse, rounded or emarginate, mostly sinuate-dentate, glabrous at maturity, shining above: cymes short-peduncled; fls. pink; sepals oblong or ovate-oblong, with large glands: drupe nearly globose, red. W. Indies.—Listed in S. Fla. as a good holly-like plant useful for dwarf hedging.

L. H. B.

MÀLUS (Greek for *apple*). *Rosàceæ.* Apple. Most botanists prefer to unite the apple and pear in the one genus Pyrus; this is the method of Bentham & Hooker in "Genera Plantarum," and of Focke in Engler & Prantl's "Pflanzenfamilien," although the recent excellent work of Schneider, "Handbuch der Laubholzkunde," keeps them distinct, as do some of the recent American authors. The evident botanical distinctions between the two groups are slight, apparently not sufficient for easy or clear determination by the unprofessional student. These differences lie in the usual presence of grit-cells in the fruits of Pyrus and their usual absence in Malus; in the hypanthium of the former being nearly closed by a cushion, and in the latter free or open; in the cavity about the stem of the fruit in Malus, a contrast which does not hold in Pyrus; and in the styles of Pyrus being distinct or nearly distinct, whereas in Malus they are more or less united. The different degrees of union of the styles has been made a basis for distinguishing the named varieties of apples among themselves, and the character does not appear to be important enough to be made the basis of generic separation. It is not impossible that the pears and apples may have had a different phylogenetic origin, but this fact itself would not be sufficient in generic description.—The apples are small trees and bushes, of some fifteen to twenty species in the North Temperate Zone. In this Cyclopedia, the cultivated apple species are described under *Pyrus;* the names of the leading species under Malus are as follows:

M. sylvestris, Mill.=*Pyrus Malus.*
M. prunifolia, Borkh.=*P. prunifolia.*
M. baccata, Borkh.=*P. baccata.*
M. coronaria, Mill.=*P. coronaria.*
M. ioensis, Brit.=*P. ioensis.*
M. Soulardii, Brit.=*P. Soulardii.*
M. angustifolia, Michx.=*P. angustifolia.*
M. Halliana, Koehne=*P. Halliana.*

L. H. B.

2308. Malpighia glabra—Barbados cherry. (×⅗)

MÁLVA (old Latin name from Greek, referring to the emollient lvs.). *Malvàceæ.* Various annual, biennial and perennial herbs, of considerable use in ornamental plantings.

From numerous allied genera, Malva is distinguished by the carpels in a single whorl: ovules solitary, ascending: bractlets 3, distinct: carpels not beaked or appendaged within. They are hirsute or nearly glabrous plants: lvs. angled, lobed or dissected: fls. solitary in the axils, or clustered, sessile or peduncled; petals 5, notched at the apex.—Species in the neighborhood of 30, in Eu., N. Afr., Asia; several are naturalized in N. Amer.—Few of the mallows are generally in the trade. The most common one is *M. moschata,* although *M. crispa* is frequently seen in gardens for its tall striking growth. They require no special cultural treatment. The genus has been more closely defined in recent time, and some of the plants that belong in Callirhoë, Malvastrum, and Sphæralcea are still likely to be listed under Malva.

2309. **Malva moschata.** (×⅖)

A. *Fls. large and showy, 1½–2 in. across.*

B. *Fr. downy, not wrinkled.*

moschàta, Linn. Musk Mallow. Fig. 2309. Perennial, 1–2 ft. high, with simple pubescence: st.-lvs. 5-parted and the parts 1–2-parted or cleft, the lobes being linear (lf.-formation variable): fls. rose or white; calyx with long, simple hairs. Eu.; cult. and escaped. R.H. 1851: 381.—A good old garden subject, with fls. varying in color shades, and run wild in grass along roadsides. The white-fld. garden form is often listed as var. **álba.**

2310. **Malva rotundifolia.** (×½)

BB. *Fr. glabrous, minutely wrinkled or veiny.*

Álcea, Linn. Much like *M. moschata,* but st.-lvs. only once 5-parted or 5-cleft, with incised or toothed lobes: fls. deep rose to white; calyx densely stellate-pubescent. Eu.; cult. and escaped. B.M. 2297. Gn.W. 4:745. (pink, veined deeper). Var. **fastigiàta,** Koch (*M. fastigiàta,* Cav. *M. Morénii,* Pollini). Lvs. less incised; upper st.-lvs. 3-fid; intermediate ones 5-fid; lobes oblong, unequally dentate. B.M. 2793. Gn. 75, p. 432.

BBB. *Fr. prominently wrinkled-veiny.*

sylvéstris, Linn. Biennial (perhaps sometimes annual or perennial), 2–3 ft. high, rough-hairy, branching: lvs. rather sharply 5–7-lobed: fls. purple-rose, large; petals 3 times length of calyx. Eu., Temp. Asia, waysides N. Amer. A.G. 13:471. Var. **mauritiàna,** Mill. (*M. mauritiàna,* Linn.), has long been cult. in cottage gardens abroad as the Tree Mallow. It is taller, smoother and has more obtuse lobes. Var. **zebrìna,** Hort. (*M. zebrìna,* Hort.), has variable fls., usually white striped with purple.

AA. *Fls. small and inconspicuous, whitish.*

B. *Lvs. not curled at the margins.*

rotundifòlia, Linn. Fig. 2310. Common Mallow. Sts. trailing from a strong, deep root: lvs. rounded kidney-shaped, crenate; lf.-stalks very long: peduncles rather slender.—Common biennial or perennial weed, not cult.: intro. from Eu. and now common in barn-, yards and waste places. The flat wrinkled fruits are known to children as "cheeses." Also locally called "shirt-button plant."

BB. *Lvs. curled or puckered at the margin.*

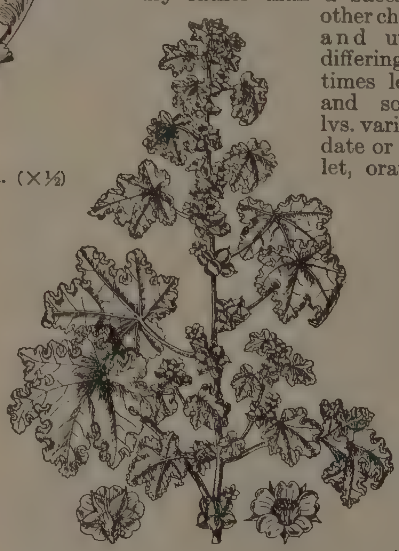
críspa, Linn. Curled Mallow. Fig. 2311. Unbranched annual, 4–8 ft. high, leafy from base to top: lvs. rounded, 5–7-lobed or -angled, attractively crisped and curled: fls. clustered, almost sessile. Eu.; sparingly escaped from old gardens. Gn. 2, p. 315.—The elegantly crisped lvs. are sometimes used for garnishing dishes. Generally self-sows in gardens. It provides a stately subject where stiff straight forms are desired; the sts. sometimes attain a thickness of 3 in. at the base.

M. campanulàta, Paxt.=Malvastrum.—*M. capénsis,* Linn.=Malvastrum.—*M. coccínea,* Nutt.=Malvastrum.—*M. involucràta,* Torr. & Gray=Callirhoë.—*M. lateritia,* Hook.=Malvastrum.—*M. miniàta,* Cav.=Sphæralcea.—*M. Papàver,* Cav.=Callirhoë.—*M. pedàta,* Torr. & Gray=Callirhoë.—*M. umbellàta,* Cav.=Sphæralcea.

Wilhelm Miller.
L. H. B.†

MALVÁSTRUM (name made from Malva). *Malvàceæ.* False Mallow. Mallow-like herbs grown with perennials.

From Malva and its allies it differs in having short or capitate stigmas on the style-branches rather than longitudinal stigmas, and a single whorl of carpels. From Malvaviscus it differs in having a dry rather than a baccate fr., and in other characters. Herbs and undershrubs of differing habit, sometimes low and diffuse and sometimes tall: lvs. various, entire, cordate or lobed: fls. scarlet, orange or yellow, short-peduncled or nearly sessile, axillary or in terminal spikes; calyx-like involucel wanting or of 2 or 3 bracts; calyx 5-cleft; petals emarginate or entire; styles 5 or more: carpels few to many, 1-ovuled, nearly or quite indehiscent and falling away



2311. **Malva crispa.** (×⅙)

from the axis at maturity.—Some 70–80 or more species, in Amer. and S. Afr. The garden species are perennials of easy cult., blooming in the hot weather.

A. *Fls. white, with eye.*

hypomadàrum, Sprague. Shrubby, sometimes reaching 10 ft., slender-branched, free-flowering: lvs. variable, usually 3-lobed and more or less toothed, sparsely soft-hairy on both sides: fls. white with rose-purple eye, about 1½ in. across, axillary, solitary or 2 or 3 together; petals obliquely obovate, retuse; calyx-lobes ovate, acuminate and ciliate; bractlets 3, spatulate-linear, ciliate. S. Afr. G.C. III. 43:394; 44:92. B.R. 295 (as *Malva capensis*).—This species was founded as late as 1908, although in cult. in Great Britain for a century under other names, as *M. capense, M. virgatum, M. grossulariæfolium.* Prop. by cuttings under glass in late spring, giving bloom in a cool greenhouse the following season.

AA. *Fls. colored.*

capénse, Garcke (*Málva capénsis,* Linn.). Shrubby and branchy, slightly viscid: lvs. ovate-oblong, somewhat 3-lobed and angled, unequally toothed: fls. 1–2 on axillary peduncles, purple; involucel variable in size, the bracts lanceolate to ovate-lanceolate and shorter than the ciliate calyx-lobes: carpels glabrous. S. Afr.—Offered abroad and also in S. Calif. Var. **Líndemuthii,** Hort., said to be a graft-variety procured by working *M. capense* on *Abutilon Thompsonii:* lvs. 3-lobed, yellow-variegated: fls. small, rose-red shaded violet. See also *Kitaibelia Lindemuthii,* p. 1738. It is doubtful whether *M. capense* is in cult.; the plants passing under this name may be *M. hypomadarum.*

laterítium, Nichols. (*Málva laterítia,* Hook.). Prostrate, hirsute, 6 in.: lvs. 3–5-lobed, truncate at base, the lobes cuneate to broad-oblong: fls. long-peduncled, solitary, brick-red; calyx-lobes ovate and spreading; involucel of 3 ovate bracts; petals round-cuneate, yellow at the base. S. Amer. B.M. 3846.—*Malva lateritia* is offered in England where the root is said to be hardy in ordinary winters, producing "very pretty peach-colored" fls. Useful for covering dry banks in the sun.

coccíneum, Gray (*Málva coccínea,* Nutt. *Cristària coccínea,* Pursh). A tufted canescent plant, 4–18 in. high, with running rootstocks: lvs. 1–2 in. across, pedately 3–5-parted or -divided, the narrow divisions again cut or cleft: fls. brick-red or coppery, in a short terminal raceme: carpels round-kidney-shaped, inclosed in the incurving calyx-lobes, 10–15, reticulated, indehiscent, 1- or 2-seeded. Neb. to Manitoba and west. B.M. 1673. Var. **grandiflòrum,** Hort., has large deep scarlet fls.

campanulàtum, Nichols. (*Málva campanulàta,* Paxt. *Málva purpuràta,* Lindl.). Two ft. or less high, hairy: lvs. pedately 3–7-lobed, the lobes deeply cut and toothed: fls. rose-purple, an inch across, in a loose terminal raceme, blooming until killed by frost; bractlets very narrow. Chile. B.M. 3814. B.R. 1362. G.C. III. 48:179; 52:193. P.M. 9:173, and R.H. 1843:325.

M. Gílliesii, Baker. More or less procumbent: lvs. hairy, palmately divided: fls. 1 in. or more across, bright red. S. Amer.—*M. spléndidum,* once listed, is probably M. Thurberi var. laxiflorum, Gray (M. splendidum, Kell.), in S. Utah to S. Calif. Shrub, becoming 12 ft. or more, gray-tomentose: lvs. roundish and mostly subcordate, 3-cleft or obscurely 3–5-lobed: fls. rosy pink, fragrant, rather loosely paniculate.

L. H. B.

MALVAVÍSCUS (Greek, *sticky mallow*). *Malvàceæ.* Shrubs and tall herbs, a very few of which are cultivated for ornament.

Usually hispid: lvs. alternate, entire, dentate, angled or lobed: fls. red, usually on axillary peduncles; petals erect and connivent or spreading in the upper half; column of stamens long and slender, exserted, only partially fertile: carpels fleshy outside, connate into a berry, later becoming dry and separating: involucel of 7–12 narrow bractlets.—Species 10 or 12, sometimes tree-like, in Trop. Amer., one reaching S. U. S. There is one species of gardens, *M. arboreus,* known to the trade as *Achania Malvaviscus.* It is a fine old greenhouse shrub with erect scarlet fls., which resemble an abutilon and never open widely. (Abutilon, however, has no involucre.)

The old *Malvaviscus arboreus* is one of the most satisfactory house-plants. It is not subject to insects of any kind, will stand a low temperature in winter, and blooms both winter and summer. When pot-grown, the plant is usually about 2 feet high, but outdoors it makes a strong branching growth, attaining 3 to 5 feet. The bright scarlet flowers remain a long time in perfect condition. The flowers open slightly at the top or not at all. This circumstance gave rise to the old name Achania, which means "not gaping." The plant needs a good light soil and thrives in a compost of fibrous peat and loam. Propagated by cuttings. The cultivator need not fear the appearance of white grains on the surface of the leaves, as they are a normal waxy secretion of the plant. (James Vick.)

2312. Malvaviscus arboreus. (×¾)

arbòreus, Cav. (*Achània Malvavíscus,* Swartz). Fig. 2312. Tall shrub: lvs. alternate, mostly 3-lobed, acuminate, heart-shaped at the base, toothed: fls. convolute in the bud, scarlet, never fully expanding; bractlets erect and narrow. S. Amer. B.M. 2305. L.B.C. 12:1155.—Cult. outdoors in S. Fla. and S. Calif.

móllis, DC. (*Achània móllis,* Ait.). Shrub, recommended for hedges in Calif.: lvs. cordate, soft and tomentose, obscurely 3-lobed: fls. scarlet, with somewhat spreading bracts. Mex. to Colombia. B.M. 2374.

Drúmmondii, Torr. & Gray. Tall perennial, to 6 ft. or more, somewhat tomentose, erect, simple or branched: lvs. round-cordate, mostly 3-lobed, as broad as long: fls. vermilion-red, 1 in. long, on axillary peduncles; bractlets of involucel narrow-spatulate; column of stamens becoming exserted: fr. berry-like, red, finally separable into carpels. Fla. to Tex. and S.—A good sun-loving plant.

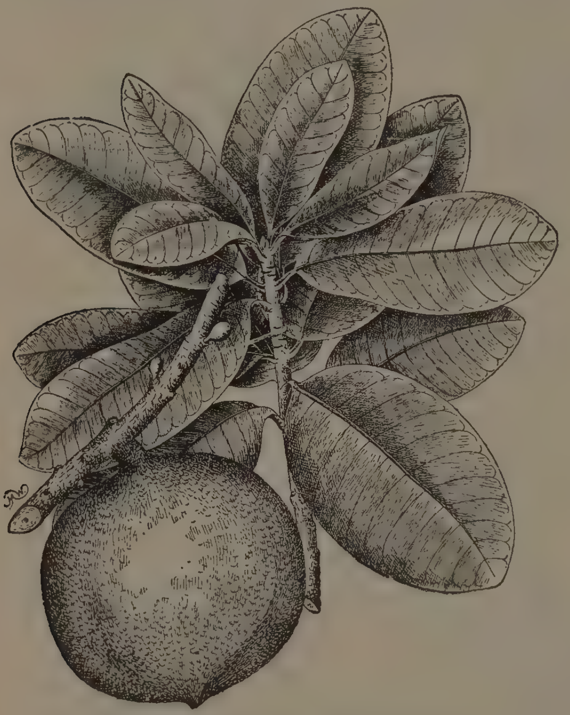
L. H. B.

MAMMÈA (from *mamey,* aboriginal West Indian name of *M. americana*). *Guttiferæ.* A very small group of tropical trees, of which *M. americana* is the only species of horticultural value. The genus is allied to the Malayan mangosteen (*Garcinia Mangostana*), but differs in its two-parted valvate calyx, closed before anthesis.

Mammea is characterized by rigid, coriaceous lvs., frequently pellucid-punctate: peduncles axillary, 1-fld., solitary or clustered; fls. polygamous; petals 4–6; stamens numerous; stigma peltate or broadly lobed; ovary 2–4-celled: fr. a drupe.—Species perhaps a half-dozen in the tropics of Amer. and Afr. but sometimes defined to include only one.

americàna, Linn. MAMMEE-APPLE. SANTO DOMINGO APRICOT. MAMEY. MAMEY DE SANTO DOMINGO. ABRICÓ DE PARÁ. Fig 2313. A large tree, 40–60 ft. or more in height, of upright, compact growth: lvs. oblong-obovate, entire, 4–8 in. long, 2–4 in. broad, rounded or blunt at the apex, coriaceous, deep green, glossy on the upper surface, marked with numerous fine transverse, reticulated veins and pellucid dots; petiole stout, ½in. or less in length: fls. solitary or clustered in the axils of the young shoots; petals white, fragrant; anthers oblong, laterally dehiscent: fr. globose, 3–6 in. diam., russet, seeds 1–4. A native of the W. Indies and N. S. Amer.

When grown on deep rich soils, the mammee-apple attains large proportions, and is one of the most beautiful and conspicuous trees in the West Indies. Its trunk sometimes attains a diameter of 3 or 4 feet, while its dense, erect but very broad crown is of a deeper, richer shade of green than that of most other trees. The large, oblong leaves appear as if varnished. The tree is cultivated for its fruit in the West Indies as well as on the mainland of tropical America. It is successfully grown in Florida as far north as Palm Beach, and though not common, fine specimens are occasionally seen at Miami and other points. While young it is very susceptible to frost. It has never been successfully grown in the open in California, so far as known, and is probably too tender for any section of that state.



2313. Mammea americana.—Mammee-apple. (×⅓)

The fruit is oblate to round in form, commonly 4 to 6 inches in diameter, the surface russet-colored and somewhat rough. The pliable leathery skin is ⅛ inch in thickness; if cut when green, a bright yellow mucilaginous sap exudes. Surrounding the one to four large, oval, rough seeds is the bright yellow flesh, juicy but of firm texture. The flavor is frequently compared to that of the apricot, and when the fruit is stewed or preserved the resemblance is rather striking. The pulp is sometimes sliced and served with wine, or sugar and cream, but is usually preferred by Europeans in the form of sauce, preserves or jam. The season of ripening in the West Indies is in the summer.

From the fragrant white flowers a liqueur is distilled in the French West Indies which is known as eau de créole or crème de créole. The wood is hard and durable, and is said to be well adapted to building purposes as well as cabinet-work; it is beautifully grained and takes a high polish. The resinous gum obtained from the bark is used to extract chigoes from the feet.

Propagation is usually by seeds, which germinate readily if planted in light sandy loam. While the tree prefers a rich well-drained soil, it succeeds remarkably well on the shallow sandy soil, underlaid with soft limestone, of the Florida east coast. Seedlings exhibit considerable variation, and do not, as a rule, come into bearing under six or seven years of age. Some asexual method should be utilized to propagate desirable varieties; inarching succeeds with the mangosteen, and should be applicable to this plant as well; budding might also be successful, performed as with the mango. Through selection of seedlings the fruit could be greatly improved; as an example, a seedling is known in the Isle of Pines in which the flesh separates readily from the seeds, although it normally adheres very closely.

F. W. Popenoe.

MAMMILLÀRIA (Latin, *mammila;* referring to the nipple-like tubercles on these plants). Often but not originally spelled *Mamillaria. Cactàceæ.* Globular or condensed small spiny cacti grown in greenhouses and some of the species in the open far South; mostly fanciers' plants.

Stems simple, branching or in a cluster from the root, commonly hemispherical or short-cylindrical, but often depressed or sometimes much elongated, the surface entirely broken up into tubercles (mamillæ): fls. usually short-funnelform, with naked or nearly naked tube and ovary, borne in the more or less woolly axils between the tubercles, or at the inner extremity of a narrow groove on their upper surface: fr. globose to linear-clavate, nearly always smooth and berry-like. The name Mammillaria is one of the generic names conserved by the Vienna rules of nomenclature, but there seems to be no justification for this except as a matter of convenience. The name Mammillaria, used for a cactus genus, was given by Haworth in 1812, but is antedated by the Mammillaria published by Stackhouse for a genus of alga. The alga name has long been reduced to synonony, but a recent study of its status seems to justify its reëstablishment. Mammillaria, as considered here, follows closely the treatment in Cyclo. Amer. Hort., but, as a matter of fact, it would be better to divide the group into 2 or more genera. Britton & Rose are preparing a monograph of the Cactaceæ in which these points will be discussed; but in the meantime, the old name Mammillaria will be retained.

The cultivation of Mammillaria differs in no respect from Echinocactus, which see.

A. *Stamens and style exserted beyond the petals; fls. irregular, slender, tubular, somewhat curved and bilabiate.* (*Subgenus Cochemiea.*)

1. **Póselgeri,** Hildmann (*M. Roseàna*, Brandeg. *M. Radliàna*, Quehl.). Upright branches 1–1½ ft. long, 1½–3 in. diam.: tubercles rather remote, flattened and appressed, later spreading: radial spines 8; central 1, brownish, strongly hooked, 1–2 in. long, twice as long as the radials: fr. bright red, flat on the broad top and much shorter than the tubercles.

2. **setispìna,** Engelm. Upright branches 8–12 in. long, 2–4 in. diam., forming dense clumps: tubercles rather crowded, ovate, short: spines white with black tips; radials 10–12; centrals 1–4, stouter, the lower one strongly hooked, often twisted, 1½–2 in. long, 2 or 3 times as long as the radials: fr. red, much exceeding the tubercles. Low. Calif.

3. **Póndii,** Greene. Upright branches 10–15 in. long, 1½–2 in. diam., making much smaller clumps than the two preceding: tubercles short, ovate, not crowded; axils setose: spines in 3 series, outer 15–25, short, white; inner 5–8, brown, longer; central row 3, brown, usually 2 of them strongly hooked, 1 in. or more in length, much exceeding the other spines: fr. oval or obovate, dull purplish red, ¾in. long. Calif.

4. **Hàlei,** Brandeg. Upright branches 1½–2 ft. high, 2–3 in. diam.: tubercles rather crowded, short-conical from a broad base: spines sub- to 3-serrate, outer 15–25; centrals 6–9, darker, the lower one much stouter, an inch or more long, usually straight but sometimes hooked, twice as long as the other spines: fr. obovate, red. Calif.

AA. *Stamens and style shorter than the petals; fls. regular, short, tubular.*

B. *Tubercle on old plant with a narrow groove on upper side: fls. from the vertex of the plant.*

C. *Fr. red; seeds black.*

D. *Color of fls. yellow.*

5. **missouriénsis,** Sweet (*M. Núttallii*, Engelm.). Nearly simple, 1–2 in. diam.: tubercles cylindric-conical, loose and spreading, slightly grooved: spines white, weak, puberulent, not hiding the body; radials 12–17, spreading; central one longer and stouter, often wanting: fls about 1 in. long, yellow to fawn-color, with reddish streak; sepals fimbriate; petals acute or acuminate: berry red, the shape and size of a small pea; seeds black and pitted. Mont. to Kans. and E. Colo.

Var. **símilis,** Engelm. Cespitose, in clumps often a foot broad: spines fewer: fl. and fr. larger. Kansas River to Texas.

Var. **robústior,** Engelm. (*M. Wissmannii*, Hildmann). Almost simple: tubercles longer and looser: spines smooth, rather short and stout; radials 10–12; central 1: fls. even larger than in *M. similis*. Texas.

DD. *Color of fls. rose.*

6. **tuberculòsa,** Engelm. (*M. strobilifórmis*, Scheer). Ovate or cylindric, rather slender, somewhat dry of texture, the spines falling from the older tubercles, leaving them as dry, corky protuberances: tubercles short-ovate from a broad base; axils densely woolly: radial spines 20–30, slender, rigid, white; centrals 5–9, stouter, purplish above, the upper longer, erect, the lowest horizontal or deflexed: fls. 1 in. diam., pale purple: fr. ¾in. long, red, with a conical cap formed of the withered remains of the fl.; seeds brown. Texas.—Four varieties of *M. tuberculosa*, vars. *cæspitítia*, *durispìna*, *pubéscens*, and *rufispìna*, which have been distributed in European collections, doubtless belong here.

7. **dasyacántha,** Engelm. Simple, subglobose: tubercles terete, loose: radial spines 25–35, hair-like, white, with brownish apex; centrals 7–13, bristle-like, pale below, brown above, longer, the most interior one horizontal, sometimes wanting: seeds black, with nearly basal hilum. Texas.

CC. *Fr. green; seeds brown.*

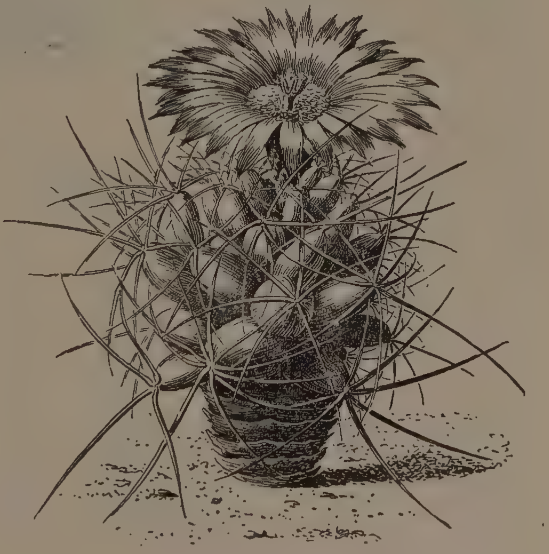
D. *The tubercles grooved only in upper half.*

8. **macrómeris,** Engelm. Fig. 2314. Low, usually soon proliferous, dark green: tubercles large and long, loose and spreading, but often incurved; groove rather short: radials 10–17, weak, slender and spreading; centrals at maturity usually 4, somewhat stouter and much longer, sometimes more than 2 in. long: fls. purple, often 3 in. in expansion; petals erose, mucronate: fr. with several scales on the ovary. Along the Rio Grande from New Mex. to Texas.

DD. *The tubercles grooved from top to bottom.*

E. *Glands 1 or more in the axils of the tubercles.*

9. **macrothèle,** Mart. (*M. aulacothèle*, Lem. *M. Léhmannii*, Otto). Sts. stout, attaining nearly 2 ft. height by 4 in. diam.: tubercles long, conical, at first upright, in age becoming even deflexed: spines all yellow; radials 6–8, spreading; centrals 1–2, longer and stouter: fls. 1½–2 in. broad. Cent. Mex.



2314. Mammillaria macromeris. (× ½)

10. **raphidacántha,** Lem. Sts. becoming 1 ft. or more long, 2–3 in. diam., often clavate: tubercles erect-spreading, somewhat flattened, often with 1 or 2 glands

in the groove: spines yellow in the young state, soon gray; radials 6–10; central 1, longer and stouter, straight or hooked in the same plant: fls. about 1 in. broad. San Luis Potosi, Mex.—The more constantly hooked form is *M. ancistracántha*, Lem. The recently described *M. radicantíssima*, Quehl., is very near *M. raphidacantha*, if not the same. It is found in the same locality.

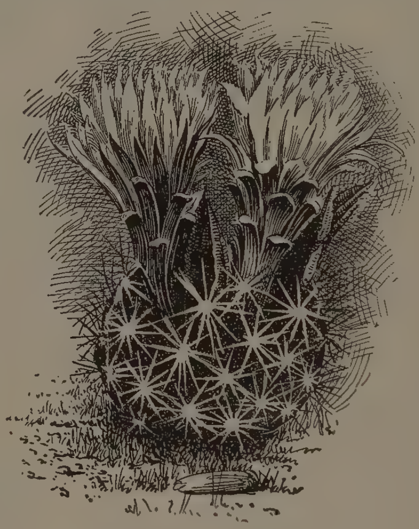
11. **erécta,** Lem. Branching from base and from decumbent sts., attaining 12 in. or more in height by 3 in. diam., bright green: tubercles conical, short, upright: spines all yellow; radials 8–13; centrals 4 or less: fls. 2–2½ in. diam. Cent. Mex.—In the groove close to the spines is often found, especially in the flowering area, a conspicuous honey-gland.

12. **recurvàta,** Engelm. (*M. recurvispìna,* Engelm. *M. nogalénsis,* Runge). Sts. depressed-globose and often deeply concave, 6–8 in. diam., forming large masses 1–3 ft. diam.: tubercles short, with usually a large gland in the groove near the apex: spines yellow or whitish, stiff, recurved-pectinate, interwoven and covering the whole plant; radials 18–20; central 1, rarely 2, recurved: fls. about 1 in. long, brownish outside. Near Nogales, Ariz., and southward in Sonora.

EE. *Glands none in the axils.*

13. **Scheèrii,** Mühlpf. (*Echinocáctus Poselgeriànus,* A. Dietr.). Sts. ovate-globose, 3–6 in. diam., usually simple: tubercles large and distant, deeply grooved, with 1–5 glands in the groove: spines stout, rigid, sometimes reddish; radials 6–16; centrals 1–5, stouter and longer, 1 very stout and porrect: fls. 2 in. long: seeds large for the genus. S. W. Texas and southward in Mex.—Muhlenpfordt described 2 species of Mammillaria under this name. The first one, founded in 1845, has purple fls., and is different from the one here described.

14. **robustispìna,** Engelm. (*M. Bròwnii,* Toumey). Much like the preceding, but tubercles teretish, no glands in the groove or sometimes a single one at apex: spines very stout; radials 10–15; central 1, longer, straight, curved or even hooked, rarely an additional straight upper one: fls. 2 in. long, with very slender tube: seeds large. Babuquibari Mts. south of Tucson, Ariz.



2315. Mammillaria vivipara. (×½)

15. **diffícilis,** Quehl. Sts. simple, nearly globose, 2½ in. diam.: radial spines 12–14; central spines 4. Mex.

16. **cornífera,** DC. Tubercles ovate, thick, rather crowded: radial spines 15–17, ashy white, 6 lines long; central 1, longer and stouter, erect, somewhat curved. Mex.

17. **daimonocèras,** Lem. Vertex impressed, very woolly: tubercles erect-conical: spines grayish; radials 20 or more, the upper accessory ones fascicled; centrals usually 3, stronger, the 2 upper divaricate and somewhat recurved, the lower horizontal or recurved. Mex.

18. **Echìnus,** Engelm. Differs from No. 17 in the less depressed shape and rather more numerous spines. S. Texas to Mex.

19. **echinoídea,** Quehl. A recent species, said to have come from Durango, Mex. It much resembles *M. Echinus.* It is also to be compared with *M. recurvata.* Fls. and fr. unknown. Not seen in Amer.

20. **scolymoìdes,** Scheidw. At length somewhat cespitose: tubercles conical, bent inward and imbricated: radial spines 14–20, whitish or horn-colored; centrals 1–4, longer and darker, the upper mingled with the upper radials, the lower stouter and bent downward: fls. 2 in. diam. Mex., south of the Rio Grande.

21. **ràdians,** DC. Sts. simple: axils naked: tubercles oval, large: spines white, rigid, subtomentose. Mex. R.B. 40:186.

22. **pectinàta,** Engelm. St. simple: tubercles quadrangular at base, conical above; areoles round-oblong: spines 16–24, yellowish, laterally compressed at base, stiff, pectinate, somewhat recurved: fls. 2½ in. diam.; petals broadest above, obtusish. Pecos River and Leon Springs, Texas.

23. **impexícoma,** Lem. Vertex deeply impressed, densely woolly: tubercles somewhat angulate; areoles round: spines 18–20, gray, rigid, covering the whole plant; very rarely a single porrect central. Mex.

24. **sulcàta,** Engelm. (*M. calcaràta,* Engelm.). Densely cespitose from the upper part of the groove: tubercles 7–9 lines long, ovate-oblong, with dilated base, somewhat imbricate, spreading in age: spines gray, rigid, subulate; radials 12–15, the upper 3–5, fascicled; central 1, recurved, wanting in younger plants: fls. 2½ in. in expansion, the tube red within; sepals not fringed. Texas, from the Brazos to the Nueces River.

25. **Níckelsæ,** Brandeg. (*M. Níckelsii,* Hort.). Very near the preceding, but radial spines more numerous, 14–18, the fascicled upper ones much longer than the lower, and no central. Mex., south of Laredo, Texas.

26. **conoídea,** DC. (*M. strobilifórmis,* Engelm.). Ovate-conical, with densely woolly vertex: tubercles short, usually densely appressed-imbricate in 8–10 spiral, rib-like rows: radial spines 10–16. straight and stout; centrals 3–5, stouter, blackish, the upper ones erect-spreading, the lower stouter, horizontal or deflexed: fls. about 1 in. in expansion, deep purple, paler outside: fr. short, buried and hidden in the axillary wool. N. E. Mex.

27. **vivípara,** Haw. Fig. 2315. Low and depressed globose, usually cespitose, forming large masses: tubercles terete and loose: radial spines 12–20, slender but stiff; centrals usually 4, but sometimes as many as 8, brownish, the upper erect-spreading, the lower stouter and deflexed: fls. bright purple, 1–1½ in. in expansion; stigmas mucronate. From S. Brit. Amer., through the upper Missouri region to E. Colo.

28. **radiòsa,** Engelm. Ovate or cylindrical, sometimes proliferous: tubercles terete: radial spines 20–30, white, with dusky apex, very unequal; centrals 4 or 5, stouter and longer, tawny, upper ones longer, lowest shorter and horizontal: fls. 1½–2 in. in expansion; stigmas obtuse. S. Texas and N. Mex.

Var. **neo-mexicàna,** Engelm. (*M. Hirschtiàna,* Haage f.). Lower, more or less proliferous from the lower grooves: radial spines 20–40, white; centrals 3–12, white below, blackish above.

Var. **boreàlis,** Engelm. Ovate or subglobose: radial spines 12–20; centrals 3–6, purple-spotted. Very near *M. vivipara.*

Var. **arizónica,** Engelm. Globose or ovate, large: tubercles long-cylindrical: radial spines 15–20, whitish; centrals 3–6, deep brown above: fls. large, rose-colored N. Ariz.

Var. **desérti,** Engelm. Low, simple, with slender nearly cylindric tubercles: radial spines 15–20; centrals

8–10, reddish tipped: fls. straw-colored, with purplish tips. Ivanpah, Calif.

Var. **chlorántha,** Engelm. Cylindrical, sometimes as much as 9 in. high: radial spines 20–25, almost in 2 series, gray; centrals 6–9, stouter, ½–1 in. long, reddish only at tip: fls. greenish yellow. S. Utah.

Var. **Álversonii,** Coulter. FOXTAIL CACTUS. Robust and branching, sometimes 10 in. long, glaucous: tubercles short and broad, somewhat angled, forming more or less distinct ribs: radial spines numerous; centrals 8–14, stout, spreading, blackish half-way down: fls. pink. S. E. Calif.

29. **cornùta,** Hildmann. Depressed-globose or hemispherical, small, grayish green: tubercles large, flattened and imbricated; areoles round: radial spines 5–7, stout, short, compressed, radiant, grayish, the upper longer; central 1, stouter, as long as the radials: fls. rose-red. "In age the spines fall off and the plant, covered with imbricated, scale-like tubercles, reminds one of a pineapple." Mex.

30. **elephántidens,** Lem. Rather large, glaucous green: tubercles very large and thick, becoming horizontal or deflexed and somewhat bilobed: spines 6–8, all radial, stout, yellowish or gray, appressed to the plant and somewhat recurved: fls. rose-color, 3 in. in expansion. Mex.

BB. *Tubercles never grooved on upper side.*

C. *Fls. large, yellow: tubercles elongated, of loose and soft texture.*

31. **longimámma,** DC. Cespitose, bright green, forming large, low clumps: tubercles sometimes more than 2 in. long: spines straight, pubescent; radials 7–10; central 1: fls. 2 in. or more in expansion. Mex.

Var. **uberifórmis,** Schum. Tubercles darker green: radial spines seldom more than 4; centrals none.

Var. **globòsa,** Schum. Tubercles dark green, very long: radial spines as many as 12; centrals 2–3.

Var. **sphǽrica,** Engelm. Tubercles about 1 in. long: radial spines 12–14; central 1. Texas.

CC. *Fls. small, usually white or red: tubercles not elongated.*

D. *Seeds black.*

E. *Base of seeds brown corky.*

32. **tetrancístra,** Engelm. (*M. phellósperma,* Engelm.) Ovate or ovate-cylindrical, rather large, simple or sparingly branched from the base: young axils sparingly setose: radial spines 30–60, in 2 series; exterior bristle-like, white; interior stouter and longer, dusky-tipped or purplish; centrals 1–4, longer, brown or blackish, sometimes all hooked, the upper ones sometimes straight: seed with a brown corky base. S. Calif. to Utah.

EE. *Base of seeds not brown corky.*

33. **micrómeris,** Engelm. Cylindrical-clavate, 1–6 in. high, covered by white spines: tubercles only ½ line long: spines on the body very short, many serial, successively shorter toward the center, not pungent; in the flowering area the upper tuft of spines having a clavate deciduous tip: fls. pinkish white, borne at the summit in a dense tuft of wool and spines, directly behind the apex of the tubercle: fr. red, smooth; seed black. Texas.

Var. **Gréggii,** Engelm. Larger in all its parts. This species and its variety really do not belong to Mammillaria although they are usually placed here by gardeners. Var. *Greggii,* which is really specifically distinct from *M. micromeris,* has been referred to Echinocactus, although superficially it has no resemblance to that genus. Weber constructed for these forms the genus Epithelantha, and this will probably be the best disposition to make of this group.

34. **elongàta,** DC. (*M. dénsa,* Link & Otto). Erect, 6–7 in. long, 1–1½ in. thick: radial spines 16–18, yellow; centrals none: fls. white or yellowish. Cent. Mex.—*M. viperìna,* Purpus, was recently distributed abroad, but has not been seen in this country. It is said to be a form of *M. elongata.* Fls. and fr. unknown.

Var. **echinàta,** Schum. (*M. echinàta* and *M. echinària,* DC.). Radials as many as 20, yellow; centrals 2–3, brown.—A stout form.

Var. **ténuis,** Schum. (*M. ténuis,* DC. *M. mínima,* Salm). Radial spines about 20, pale yellow; centrals none.—The most slender form, only ½in. thick.

Var. **stélla-auràta,** Schum. Sts. somewhat thicker: spines golden yellow; 1 central usually present.

35. **Leòna,** Poselg. Sts. stouter, glaucous, upper axils woolly: radial spines about 30, radiant, slender, white; centrals 6–12, much stouter; the upper ones longest, ivory-white at base, dove-color or bluish above. Nuevo Leon, Mex.

36. **decípiens,** Scheidw. (*M. Guilleminiàna,* Lem.). Irregularly cespitose, somewhat clavate, often rosy: tubercles cylindrical; axils sparingly bristly: radial spines 7–12, whitish; centrals 1–2, brown, longer; all slender. Mex.

37. **dumetòrum,** Purpus. Minute plants, less than 1 in. diam.: tubercles prominent, terete, bearing long white hairs in their axils; spines spreading, white except at the yellow bases: fls. 6–7 lines long. Cent. Mex.

38. **frágilis,** Salm. Sts. low, usually as broad or broader than high, extremely proliferous, the offsets so lightly attached that they soon fall by their own weight: radial spines 12–14 ,white; centrals none or 1, rarely 2, white, with dusky tip. Mex.

39. **lasiacántha,** Engelm. Low, usually globose or depressed-globose: tubercles slender, axils naked: radial spines as many as 40–80, feathery; centrals none. Texas.

Var. **denudàta,** Engelm. (*M. Rúngei,* Hort.). Larger, both plant and tubercles: spines naked.

40. **plumòsa,** Web. Densely cespitose, at length forming masses 6–10 in. diam.: axils long-hairy: radial spines about 40, feathered to the tip; centrals none.—This and the preceding are like feathery balls. *M. plumosa* is sold usually under the name of *M. lasiacantha,* to which it appears to be rather closely related. N. Mex.

41. **senìlis,** Salm. "Proliferous at base: axils not setose: tubercles crowded: spines all white; exterior very numerous, erect-spreading, hair-like, flexuous; centrals 4–6, a little stronger, the upper and the lower hooked." Chihuahua, Mex.

42. **barbàta,** Engelm. Globose-depressed: axils not setose: exterior spines very numerous, pilose; interior stronger, yellowish, 10–15; central solitary, stout-hooked, yellowish, not much longer than the others: fls. small, not remote from the center; sepals fimbriate; berry "green." Near Chihuahua, Mex.

43. **vètula,** Mart. Subglobose or becoming subcylindrical: axils not setose: radial spines bristle-like, at first 25–30, obliquely spreading, later twice as many and horizontal; centrals 1–3, yellowish brown, scarcely stouter or longer. Mex.

44. **cándida,** Scheidw. (*M. sphærótricha,* Lem.). At length cespitose, globose, becoming longer: vertex depressed: axils setose: radial spines bristle-like, more than 50, horizontal and interwoven; inner spines, 8, 10 12, or more, a little stouter and upright: fls. flesh-color or pinkish.

45. **pusílla,** DC. (*Cáctus stellàtus,* Willd. *M. stellàris,* Haw.). Low, globular, proliferous, making large masses: tubercles cylindrical, small and loosely spreading; axils with long, hair-like, tortuous bristles: radial spines 12–20, very soft and flexuous; centrals 4–6, yellowish, a little rigid, pubescent: fls. yellowish white. W. Indies.

Var. **múlticeps,** Salm. Larger: tubercles upright, crowded: radial spines numerous; centrals 6–8, slender, pubescent, reddish yellow. Mex.

Var. **texàna,** Engelm. Larger than the last: spines in 3 series; outer capillary, crisped, 30–50; interior 10–12, a little more rigid, pubescent, white; centrals 5–8, longer, stouter, pubescent, yellow at tip. Texas and adjacent Mex.

46. **Bocasàna,** Poselg. Depressed-globose, or a little lengthened, at length densely cespitose: axillary bristles as long or longer than the tubercles: radial spines 25–30, white, stiff at the base, each ending in a flexuous thread; centrals 2–3, slender, porrect, short, all yellow with brown tips, the hooked one brown nearly to the base, pubescent. Mex.

47. **Kunzeàna,** Bödeker & Quehl. Plants small, growing in cespitose clusters, light green: tubercles cylindrical, with bristles in their axils: radial spines about 25, white, delicate but stiff; central spines 3 or 4, yellowish brown, one of them hooked: fls. white, with the outer lobes rose-colored. Mex.

48. **Wìldii,** A. Dietr. (*M. Wildiàna,* Otto). Cespitose, forming hemispherical clumps: radial spines 8–10, very slender, white, spreading; centrals usually 3–4, a little stouter and longer, honey-yellow, brown at base, pubescent, 1-hooked. Mex.

49. **dioìca,** Brandeg. (*M. Goòdrichii,* of Calif.). Simple or cespitose from the base, ovate to cylindrical, 3–8 in. high: tubercles somewhat angular and leathery: radial spines 11–22, white, with brown or purple tips; centrals 1–4, longer and darker, the upper turned up among the radials, the lower porrect and strongly hooked: fls. often unisexual, yellowish white with rosy streak. Calif. and Low. Calif.

Var. **insulàris,** Brandeg. (*M. Pálmeri,* Coulter, not of Jacobi). Sts. densely cespitose, shorter: axils densely woolly: spines much whiter, usually all straight. San Benito Isl.

50. **armillàta,** Brandeg. Taller, often 1 ft. high, branching at base and along the st.: tubercles crowded: radial spines 9–15; centrals 1–4, nearly twice as long: fls. small, yellowish, scarcely spreading. Low. Calif.—The plant is marked by dark circular bands.

51. **Wrìghtii,** Engelm. Globose or depressed, top-shaped below: radial spines 8–12, white, pubescent; centrals 1–3, reddish black, scarcely longer than radials, all hooked: fls. about 1 in. long, purple. New Mex.

52. **Goòdrichii,** Scheer. Erect, cylindrical, branching at base: axils naked: radial spines about 12, white; centrals 4, white below, brown above, the 3 upper erect-spreading, the lower longer. Cedros Isl. and Low. Calif.

53. **Gràhamii,** Engelm. Globose or ovate, somewhat cespitose: radial spines 15–30, white, often dusky at tip, the upper ones shorter; centrals usually 4, usually blackish from a paler base, the 3 upper turned up among the radials, and, when pale, hardly to be distinguished from them; lower porrect: fls. rose-colored, 1 in. expansion: fr. nearly 1 in. long. From Texas to S. Calif. and adjacent Mex.

54. **fasciculàta,** Engelm. (*M. Thórnberi,* Orcutt). Plants sometimes growing in large clusters often containing many plants (as many as 110 have been noted): sts. cylindrical, usually 2–4 in. high but sometimes as much as 1 ft. high: radial spines 13–18, white, with dark tips: fls. broadly funnel-shaped, purplish; petals broad-acute. Ariz.—This species, although collected in 1848, has been poorly represented in our collections and unfortunately has recently been re-named. It is a very beautiful species.

55. **mazatlanénsis,** Schum. (*M. littoràlis,* Brandeg.). Plants growing in dense clusters, much branched at base: sts. globular to short cylindrical: spines numerous, usually brown and completely hiding the plant. West coast of Mex.; sometimes erroneously referred to Calif.—This species does not do well in cult.

56. **venùsta,** Brandeg. Globose or hemispherical, small, often cespitose: tubercles very thick and blunt, concave at the end, usually extremely glaucous: radial spines 9–15, stout, from pure white to white below and brownish above; central commonly 1, sometimes 2 or 3, the lower little longer and darker than the radials: fls. rose-color, 1½ in. in expansion: fr. scarcely juicy, nearly 1 in. long, circumscissile near the base. S. Low. Calif.

57. **Maìnæ,** Brandeg. Hemispherical to ovate, usually simple: tubercles somewhat incurved, glaucous, the lower part and the axils often bright rose-red: radial spines 10–15, yellowish becoming gray, the upper shorter; centrals 1–3, the upper shorter and smaller, turned upward, one of them sometimes hooked, lower central stout, strongly hooked, somewhat twisted, yellowish below, black at tip: fls. flesh-color: fr. shorter than the tubercles. Vicinity of Nogales, Ariz.—Sent out as *M. Galeottii.*

58. **Cárretii,** Schum. Simple, depressed-globose, rather small: radial spines spreading-recurved and interwoven, rather long, yellowish; central 1, slender, chestnut-brown, paler below: fl. whitish, with rosy streak in petals; sepals long-acuminate. Mex.—The only specimen seen has bristles in the axils.

59. **eriacántha,** Link & Otto. Cylindrical, elongated, ½ft. and more in height ("reaching 20 in.") by 2–2½ in. diam.: tubercles crowded, acutely conical: spines all pubescent; radials 20–24, pale yellow, bristle-like; centrals 2, stronger, nearly twice as long as the radials, golden yellow, one directed upward, the other downward: fls. yellow, small: fr. yellow. Mex.

60. **sphacelàta,** Mart. Sts. cespitose, cylindrical, 6 in. or more long, 1 in. diam.: tubercles short, conical from a broader, rhombic base: spines ivory-white with blackish tips; radials 12–18, horizontal-spreading; centrals 3–4, upright: fls. small, the petals acute. Mex.—The proper position of this and of the preceding species is still quite uncertain.

DD. *Seeds brown.*

E. *The tubercles not exuding milk when pricked.*

61. **spinosíssima,** Lem. Sts. cylindrical, reaching 1 ft. high and 2½ in. diam.: tubercles short, ovate-conic, somewhat tetragonal: radial spines 20–25, setiform, white, spreading; centrals 12–15, brownish red, stronger and twice the length of the radials. Mex.

Var. **sanguínea,** Haage. St. somewhat clavate, rather shorter and stouter: radial spines 18–20, spreading, white; centrals 8, only a little longer, but thicker and bulbous at base, white with brownish base and dark brown tip, the young ones dark blood-red. Mex.

62. **rhodántha,** Link & Otto (*M. Odieriàna,* Lem. *M. fulvispìna,* Haw.). St. long-cylindric or clavate, reaching more than 1 ft. high, usually 2-parted: axils bristly: radial spines 16–20, white, bristle-like, horizontal-spreading; centrals 4–6, rigid, white or yellowish, the upper black at tip. Mex.

Var. **pyramidàlis,** Schum. Central spines dark brown, the young ones ruby-red.

Var. **Pfeìfferi,** Schum. (*M. aurèiceps,* Lem.). Radial spines 25 or more, yellow; centrals 6–7, recurved spreading, golden brown.

Var. **crassispìna,** Schum. Radial spines 24–27, whitish; centrals 6–7, larger and stouter, more curved, darker.

Var. **fuscàta,** Schum. Axils naked; tubercles 4-angled at base: radial spines 25–28, radiant, bright yellowish brown; centrals 6, stout, strongly curved, the upper very long.

63. **dolichocéntra,** Lem. (*M. tetracántha,* Hook.). Subglobose (but said to reach a yard in height): tuber-

cles somewhat 4-angled; areoles elliptic or rhombic: radial spines none; centrals 4, slender, rigid, the upper curved upward, 1–1½ in. long, the 3 lower half as long, all grayish brown. Mex.

Var. **Galeóttii,** Foerst. Radial bristles 8–14, very short, soon falling; centrals 4, seldom 1 or 2 more, spreading, yellowish, with points, the upper and lower longest. Mex.

64. **díscolor,** Haw. Globose or ovate, glaucous: outer spines 16–20, white, radiant; interior 6, rigid, recurved, white below, black above, upper and lowermost very long. Mex.

65. **Lesaunièri,** Schum. Hemispherical or very short-cylindrical (habit of *M. Heyderi*): spines brownish, short; radials 11–13; central upright, stronger.

66. **Haageàna,** Pfeiff. Cespitose: heads small, at length cylindrical, slender: tubercles small, crowded; axils woolly: radial spines about 20, pure white, only about 1½ lines long; centrals 2, black, slender, elongated, upper 3, lower 4 lines long. Mex.

67. **élegans,** DC. (*M. acanthophlégma,* Lehm. *M. Potosìna,* Hort. *M. Klùgii,* Ehrb.). Simple, then proliferous and densely cespitose, depressed-globose, later lengthened: tubercles crowded, very small: radial spines more than 20, bristle-like, about 3 lines long, pure white, interwoven and covering the whole plant; central spines 2 (1–3), with brown tips, the one directed upward, the other downward, about twice as long as radials, in the axils abundant long white wool. Mex.

2316. Mammillaria meiacantha. (×½)

EE. *The tubercles exuding milk when pricked.*

68. **bícolor,** Lehm. Simple or proliferous: tubercles small, crowded, ovate-pyramidal: radial spines 16–20; centrals 2, less than 1 in. long, stouter, erect, black-tipped. Mex.

Var. **nívea,** Schum. Obovate proliferous tubercles conical: radial spines capillary; centrals 4, white, with dusky apex, upper one incurved, 1 in. long.

69. **Párkinsonii,** Ehrb. At length dichotomously divided: tubercles slenderly pyramidal; axils woolly and bristly: radial spines 20 or more, slender; centrals 2, 3, 4, rarely 5, brown-tipped, the upper ones 3–4 lines long, the lower 1½ in. turned downward. Mex.

70. **formòsa,** Scheidw. Nearly simple: tubercles 4-angled: radial spines 18–22, rather rigid; centrals 6, a little longer, stiffer, thickened at base, reddish or brownish tipped.

71. **angulàris,** Link & Otto (*M. subangulàris,* DC.). Densely cespitose: axils of the young tubercles setose as well as woolly: radial spines 3–7, the upper ones often very short, the lower one sometimes 3 in. long, occasionally a very long central present. Mex.

72. **árida,** Rose. Sts. usually simple, globular, deeply seated in the ground, 1–2 in. diam.: tubercles very milky, nearly terete: radial spines about 15, pale, with dark tips; central spines 4–7: fls. 6 lines long; petals cream-colored to a pale yellow: fr. clavate; seeds brown. Only known from the collection made by J. N. Rose on an island in the Gulf of California near La Paz in 1911.

73. **petróphila,** Brandeg. Sts. depressed-globose to short-cylindric, 6 in. high: tubercles milky, about 5 lines long: spines chestnut-brown or paler at base; radial spines 8–10; central spines 1 or 2: fls. greenish yellow. Mountains of S. Low. Calif.

74. **centricírrha,** Lem. (*M. arietìna,* and *M. deflexispìna,* Lem. *M. Foèrsteri* and *M. Kràmeri,* Mühlpf. *M. Schmídtii,* Sencke. *M. tetracántha,* Hort.). Copiously proliferous: tubercles pyramidal, 4-angular: spines irregular, mostly 4–6 radials and 1 central, sometimes only 1, sometimes 2 centrals with 1–2 very short radials or none; radials very stout, straight or curved, awl-shaped, reaching ¾in.; central stouter, sometimes nearly 2 in. long; young spines yellow. Mex.

75. **mutábilis,** Scheidw. (*M. autumnàlis,* Dietr. *M. cirrhífera,* Mart.). At length sparingly cespitose, depressed-globose or short-cylindric: tubercles pyramidal, 4-angled; axils with stout bristles in the wool: radial spines 1–6, very small; centrals 1–4, angled, flexuous, much longer, particularly the upper one, which reaches 2 in. Mex.

76. **Heeseàna,** McDow. (*M. Pètersonii,* Hildmann). Simple, glaucous or ashy green: tubercles pyramidal, 4-angled: radial spines 10–14, the 3 upper pure white and very short, the remainder longer and brownish-tipped; centrals 4, the upper ones erect and forming an elevated covering for the top of the plant, the lower one the longest, 2 in. long, and projecting. Mex.—Varies in color of spines.

77. **símplex,** Haw. Globose or short-cylindric: radial spines 12–17, the middle ones longest; centrals 4–5, somewhat longer, reddish: fl. brownish green without, yellowish or whitish green within: fr. red, ⅔in. long, clavate; seed brown.—This is the *Cactus Mamillaris* of Linnæus and the first species discovered. It has for many years been a desideratum in our collections, although various species have recently been referred to it, like *Mammillaria nivosa* and *M. pusilla.* It has recently been re-discovered on the Isl. of Curacao and in N. Venezuela. This is the only species known from the S. American continent.

78. **nivòsa,** Link. Grows in clusters of 25 or more specimens, forming clumps 2 ft. diam.: largest individual specimens sometimes 6 in. diam.: spines all yellow: tubercles very woolly in their axils: fls. cream-colored. Common on exposed cliffs of many of the W. India Isls. —A very beautiful species, but not often seen in cult.

79. **hidalgénsis,** Purpus. Sts. simple, cylindrical, sometimes 1 ft. high: radial spines none; central spines 4: fls. crimson. Cent. Mex.

80. **crucígera,** Mart. Sts. cylindrical, 4–6 in. high: tubercles closely set, with their axils full of white wool: radial spines numerous, 20 or more, bristle-like and spreading; central spines 4, yellowish: fls. crimson or purple. Mex.—An old species recently intro. into cult.

81. **Brándegei,** Coulter (*M. Gábbii,* Coulter). Depressed-globose to short-cylindric or clavate: tubercles slender: radial spines 9–16; centrals 1–4, sometimes shorter than the radials, and stout, sometimes longer and slender, white to brown: fls. reddish brown without, brownish green within: fr. clavate, white, tinged lilac. Cent. Low. Calif.

82. **Heỳderi,** Mühlpf. (*M. texénsis,* Lab.). Tubercles slender: spines short; radials 16–18, short, slender, white; central 1, darker, shorter than the lower radials, brown: fls. yellowish, with pale rosy streak in the petals. Ariz. to Texas.

Var. **applanàta,** Engelm. Body much depressed, summit flat or concave: radial spines 15–22. Texas.

Var. **hemisphǽrica,** Engelm. Top rounded: radial spines 9–12. N. E. Mex.

83. **Macdoùgalii,** Rose. Plants low and somewhat flattened on top, but very old plants nearly globular and then about 5 in. diam.: tubercles flattened dorsally, strongly angled: radial spines 10–12, white or somewhat yellowish, tipped with brown or black; central spines 2, stout, yellowish, with brown tips: fls. over an inch long, cream-colored: fr. red, clavate. Common in the mountains about Tucson, Ariz., where it was collected by D. T. MacDougal, for whom it is named. This species is related to the Texan species commonly known as *M. Heyderi.*

84. **meiacántha,** Engelm. Fig. 2316. Usually simple: tubercles rather large, sharply angled and 4-sided, pyramidal: radial spines 5–9, mostly 6, white or yellowish; central 1, rarely a second, shorter and darker than the radials: fls. whitish, with reddish streak. Texas.

85. **cárnea,** Zucc. Body dark green: tubercles rather large, pyramidal, 4-angled: radial usually none, rarely 1–2; centrals commonly 4, in upright cross, stiff, grayish, with darker tip, in young growth dark brown or reddish: fls. reddish flesh-color. Mex.

86. **uncinàta,** Zucc. Depressed-globose to subclavate: tubercles pyramidal, not strongly angled: radial spines 4–6, short, gray, dark-tipped; centrals 1, rarely more, longer and stronger, strongly hooked, dark. Mex.

87. **Trohártii,** Schum. Globose or depressed, small: tubercles very small, conical, scarcely angled: radial spines 5, white with dark brown tips, the lower longest; central 1, dark brown, stiff. Mex.

88. **sempervìvi,** DC. Globose, blackish green, axils woolly: tubercles short, angled: radial spines 3–7, very short, only found on young tubercles; centrals only about 2 lines long, stout, conical, reddish, later gray: fls. dull white with reddish streak. Mex.

89. **Caput-Medùsæ,** Otto. Depressed-globose, dull glaucous green, small: tubercles slender, angled at base: spines 3–6, very short, subulate, straight, reddish when young, later gray, pubescent: fls. whitish, red-streaked. Mex.

Mammillarias, in common with other cacti, run into many forms. Some of these forms may be valuable to the horticulturist, and yet not sufficiently distinct to warrant the giving of definite botanical names. The following names, not accounted for in the above review, are offered in the catalogues of American dealers: *M. Brándii.*—*M. brùnea.*—*M. cirrhífera longispìna* (see No. 75).—*M. Donátii.*—*M. filipéndula.*—*M. fuscàta Leòna* (see Nos. 35, 62).—*M. Lassòmeri*=M. Lesaunieri(?).—*M. melonácantha* is an uncertain garden name.—*M. montàna.*—*M. Nícholsonii*=M. Nickelsæ(?).—*M. Rebsamiàna.*—*M. recúrvens.*—*M. rigidispìna.*

The following species, mostly recently described, have appeared in foreign publications. None of them is being grown in Amer.: *M. Boedekeriàna,* Quehl.—*M. bombycìna,* Quehl.—*M. camptotrícha,* E. Dams.—*M. collìna,* Purpus.—*M. cordígera,* Heese.—*M. Emskoetteriàna,* Quehl.—*M. Joosensiàna,* Quehl.—*M. Knippeliàna,* Quehl.—*M. Múndtii,* Schum.—*M. napìna,* Purpus.—*M. pilispìna,* Purpus.—*M. ramosíssima,* Quehl.—*M. Ruèstii,* Quehl.—*M. Sártorii,* Purpus.—*M. Seideliàna,* Quehl.—*M. trichacántha,* Schum.—*M. unisèta,* Quehl.—*M. Verhærtiàna,* Boedeker.

The following species are likely to appear in the trade at any time: *M. ceratìtes,* Quehl. This species has been associated with M. Delætiana and M. durangensis, but it seems to be very close to M. conoidea. It has not yet been intro. into American trade.—*M. Delætiàna,* Quehl. Sts. club-shaped, about 3 in. high: tubercles grooved on the upper side: fls. large, pale yellow. Mex., sometimes credited to Calif.—*M. durangénsis,* Runge. Very beautiful species with small central fls. Does not grow well in cult.—*M. pseudoperbélla,* Quehl. A species recently intro. into Eu. Very close to M. elegans. Not yet cult. in Amer.

J. N. Rose.†

MANDARIN ORANGE: *Citrus nobilis* var. *deliciosa.*

MANDEVÍLLA (Henry John Mandeville, British minister at Buenos Ayres). *Apocynàceæ.* Tall climbers from the warmer parts of America, with large funnel-shaped, 5-lobed flowers which are yellow, white or rarely tinged violet.

Woody plants: lvs. opposite, penniveined: racemes simple, often 1-sided, loose, dense or reduced to 2 or 3 fls.; calyx 5-parted, with several glands inside at the base or 5 scales; corolla-tube cylindrical, funnel-shaped, or ovoid; lobes 5, broad, twisted; stamens fixed at the apex of the tube, included; disk of 5 lobes or scales; ovary of 2 distinct carpels; stigma thick: follicles erect or divergent, incurved and more or less cohering at apex, terete or angled.—Species 50 or more, Mex. to Argentina, but some of them probably to be referred to Echites or elsewhere. The species are little known as cult. subjects. The plants resemble Dipladenia, which see for cult.

suavèolens, Lindl. (*Echìtes funifórmis,* Gris., not Vell.). Sometimes called Chilean jasmine because of its climbing habit and large white or blush fragrant fls.: lvs. cordate, stalked, glabrous above, glaucous beneath; stipules pectinate: racemes with about 9 fls. each 2 in. across. Argentina. B.R. 26:7. B.M. 3797. G.C. III. 2:817. P.M. 16:289. R.H. 1845:167; 1913, p. 424. J.H. III. 48:413. G. 29:443. Some of the foregoing portraits may represent the following species, as the two have been confused.—Characterized by a pale, fleshy pectinate ring between the base of the calyx and corolla.

Tweedieàna, Gad. & Stapf. Much like *M. suaveolens,* differing in having glabrous branches, long-acuminate or almost caudate lvs., longer petioles, lanceolate bracts, more fragrant fls. with lanceolate sepals, brilliant white corolla-limb and green tube. Probably Argentina. R.H. 1913, p. 425.

Wilhelm Miller.
L. H. B.†

MANDRÁGORA (name used by Hippocrates, said to signify that the plant is hurtful to cattle). *Solanàceæ.* Mandrake. Old medicinal herbs.

A genus of three or four species, one of which is supposed to be the dudaim mentioned in Genesis, chapter 30. In America the name mandrake is applied to the mayapple, *Podophyllum peltatum,* but the mandrake of history is a plant with a large spindle-shaped root which was supposed sometimes to become forked and resemble the human form. In this condition it was used as an aphrodisiac. The plant was also called love-apple, and many superstitions about it still survive. The old herbals abound in fanciful pictures of the mandrake, one of which is reproduced in Fig. 2317. *M. officinarum* may be cultivated in the hardy border for its folk-lore interest. *M. autumnalis* is supposed by some to be the true mandrake. Both are natives of the Mediterranean region. *M. caulescens* is found in the Himalayas. The mandrakes are allied to belladonna (Atropa) and have poisonous qualities.

2317. Mandrake.
From an old herbal.
(See Mandragora).

Mandragoras are mostly stemless perennial herbs with thick roots and large, stalked, wavy-margined lvs., the later ones being usually narrower and entire, and rather large fls. varying from whitish through bluish violet and purplish shades: fls. purple, bell-shaped, about 5-cut, netted-veined and borne in clusters among the tufted lvs.; calyx deeply 5-cut; sinus of the corolla induplicate between the lobes; stamens 5: fr. a globose or oblong juicy berry.

officinàrum, Linn. (*M. officinàlis,* Mill. *Átropa Mandrágora,* Linn.). Mandrake. Lvs. ovate, the first obtuse, the others acuminate: calyx-teeth lanceolate, as long as the oblong berry. R.H. 1897, p. 131.

Wilhelm Miller.

MANDRAKE in America means the mayapple (Podophyllum) but the mandrake of history is *Mandragora,* above.

MANÉTTIA (Xavier Manetti, of the botanic garden at Florence, born 1723). *Rubiàceæ.* Twining plants sometimes grown under glass for the ornamental flowers.

Glabrous or villous graceful climbers, evergreen: lvs. stalked, usually long-acuminate: fls. small or rather large, axillary, solitary or in short corymbs or panicles, white, yellow or red; calyx-lobes 4, rarely 5, short or long, narrow or broad; corolla-tube short or long, terete or angled, straight or curved, glabrous or pilose within; limb 4- (rarely 5-) lobed, the lobes usually short and erect or recurved, valvate; stamens 4 or 5, inserted at the orifice or in the throat of the corolla; disk annular or cushion-like; style filiform, the stigma entire or bifid: fr. an obovoid or turbinate 2-grooved 2-celled dehiscent many-seeded caps.—Perhaps 40 species, in warmer parts of Amer.

This genus includes the common manettia vine, *M. bicolor* and *M. inflata*, which have scarlet tubular flowers an inch or more long, with five spreading yellow tips. They are twining plants and are often trained to pillars and trellises both indoors and out, as they bloom more or less the year round. They can also be trained into a bushy form. The manettia vine is a rather old-fashioned plant, and generally easy of culture. It is fairly satisfactory as a cool conservatory vine, but is an easy prey to red-spider and mealy-bug. The flowers are short-lived, and not the best for cutting. Some gardeners prefer it to cupheas or *Jacobinia penrhosiensis*. Manettias are propagated by cuttings of young growth inserted in sand with bottom heat. For summer use the vines should have a sheltered but sunny position.

Manettias are very useful as roof-plants, or for growing on rafters and pillars. They may also be grown into specimen plants trained on a wire trellis. They may be rooted in a temperature of 60° to 65°. Put them in sand about 1 inch apart, shading them from the sun. Roots will soon form, when they may be potted, singly, in small pots, in two parts loam, one of leaf-mold, and one of sand. When the plants have gripped the soil, pinch out their points to encourage them to break. Put a few thin stakes around the pot to which to tie the shoots until they are large enough to be trained in their permanent position. Never allow the plants to become pot-bound, until the desired size of pot is attained, and be careful that the shoots do not get all tangled up, as it would be difficult to separate them, when it is desired to train them on a trellis, or in some other desirable position. Loam two parts, equal parts sand, and flaky leaves, a small part of well-rotted manure, is a good potting medium, for all future pottings. The night temperature should never be less than 55°. In summer, the plants that are grown on a trellis, in pots, may be placed outdoors on a bed of ashes, until the middle of September. Syringe manettias freely, as this keeps red-spider in check. Other insect pests may be kept down by fumigating with hydrocyanic gas as advised for other plants. (George F. Stewart.)

A. *Corolla of practically the same color throughout.*

glàbra, Cham. & Schlecht. (*M. cordifòlia*, Hort., not Mart.). Glabrous, much branched, woody below: lvs. cordate-ovate-acuminate, very short-petioled, glabrous and shining: fls. single on elongated solitary peduncles, crimson; corolla 1½ in. long, clavate-funnel-shaped, quadrangular; limb 4-parted, the short segms. deltoid and revolute; disk cushion-shaped; stamens conspicuously exserted. S. Brazil, Paraguay, Uruguay, Argentina. B.M. 3202. B.R. 1866. P.M. 2:267. B. 2:87 (all as *M. cordifolia*). The true *M. cordifolia*, Mart., apparently not in cult., is pubescent, with spreading corolla-lobes and included stamens.

mìcans, Poepp. & Endl. Handsome, differing from *M. glabra* in larger fls. which are borne several together on short axillary branches; the corolla-lobes spreading, and anthers nearly sessile; and the petioles shorter: fls. bright red-orange. Andes region, Peru and Bolivia to Argentina. B.M. 5495.

coccínea, Willd. Probably not in cult., and its position apparently doubtful: twining: lvs. oval or ovate, long-acuminate, tapering to base: fls. scarlet (pinkish?), on rather stout bracted peduncles; corolla salver-shaped, the 4 lobes pointed and spreading-reflexed, the throat closed with yellow hairs and stamens included; disk hollow and adnate to calyx-tube; sepals apparently 8. Mex. to Colombia. B.R. 693.

miniàta, Lem. Twining, somewhat white-hairy: lvs. oval-elliptic, thick, the base long-attenuate and apex acute or subacuminate, grayish pilose above: fls. solitary or twin, long-peduncled, cinnabar-red shading to rose; corolla funnel-shaped, hairy, the lobes 4, pointed, spreading; stamens included. Probably Andean, and very likely not now in cult. F.S. 4:317.

AA. *Corolla yellow at apex.*

bícolor, Paxt. Twining, glabrous: lvs. nearly sessile, lanceolate, slightly glaucous, acuminate: fls. single on short axillary peduncles; corolla ¾in. long, little swollen at base, red below and yellow toward the top, the short lobes spreading-reflexed; calyx-lobes erect or spreading; style exserted. Brazil. P.M. 10:27.

inflàta, Sprague (*M. bícolor*, Hort., in part). Fig. 2318. Recently separated from the cult. *M. bicolor:* differs in its leafy reflexed calyx-lobes, the corolla swollen at base, more coarsely hairy, and the yellow part of corolla much smaller; anthers not apiculate; style (in long-styléd plant) about as long as corolla-tube. Paraguay and Uruguay. B.M. 7776 (as *M. bicolor*). G.C. III. 36:384.

L. H. B.

2318. Manettia inflata. (×⅓)

MANFRÈDA ("named after an ancient writer on simples whose work is in the Parisian library"). *Amaryllidàceæ*, tribe *Agavoídeæ.* Acaulescent bulbous plants, of somewhat the aspect of Polianthes, but with nearly straight usually solitary flowers; closely allied to Agave, and requiring similar culture.

Leaves thin, lance-oblong, usually denticulate, dying in winter: infl. a raceme; fls. nocturnal, greenish or purplish white, tubular with spreading limb and protruding style and stamens. Chiefly Mexican. Monograph by Rose in Contr. U. S. Nat. Herb. 8, Part I, 1903. The lvs. of most species are wavy or crisped at the margin.

A. *Lvs. pubescent.*

maculàta, Rose (*Poliánthes maculàta*, Mart. *Agàve pubéscens*, Regel & Ortg. *A. brachystàchys pubéscens*, Terr.). Lvs. brown-spotted: infl. 3 ft. high; fls. subsessile, 1¼ in. long; tube much longer than segm.; stamens long-exserted. S. Mex. Amoen. Bot. Monac. 19:13.

AA. *Lvs. glabrous.*

B. *Stamens little exserted.*

maculòsa, Rose (*Agàve maculòsa*, Hook. *A. maculàta*, Engelm.). Fig. 2319. Lvs. somewhat glaucous, mottled: infl. 3 ft. high; fls. subsessile, 2 in. long; tube somewhat longer than segm.; filaments in the throat. Texas. B.M. 5122. Bull. Soc. Tosc. Ort. 3. p. 308.

BB. *Stamens long-exserted.*

C. *Tube of perianth longer than segm.*

virgínica, Salisb. (*Agàve virgínica,* Linn. *A. pállida,* Salisb. *A. carolinénsis,* Lets. *A. Alibértii,* Baker. *Alibértia intermèdia,* Mar. *Alòe caroliniàna,* Hill. *A. virgínica,* Crantz). Lvs. green: infl. 3–5 ft. high, glaucous; fls. scented like mace, short-stalked, 2 in. long; tube thrice as long as segm.; filaments inserted at its base. S. U. S. Hardy. B.M. 1157. Jacq. Icon. 378. Lam., Encycl. 235. Hill, Hort. Kew. 13. Contr. U. S. Nat. Herb. 5, p. 155; 8, p. 15. Rep. Mo. Bot. Gard. 7:26, 27, 63. B.B. 1:445.—A form with mottled lvs. is var. **tigrìna,** Rose (*M. tigrìna,* Small. *Agàve virgínica tigrìna,* Engelm.).

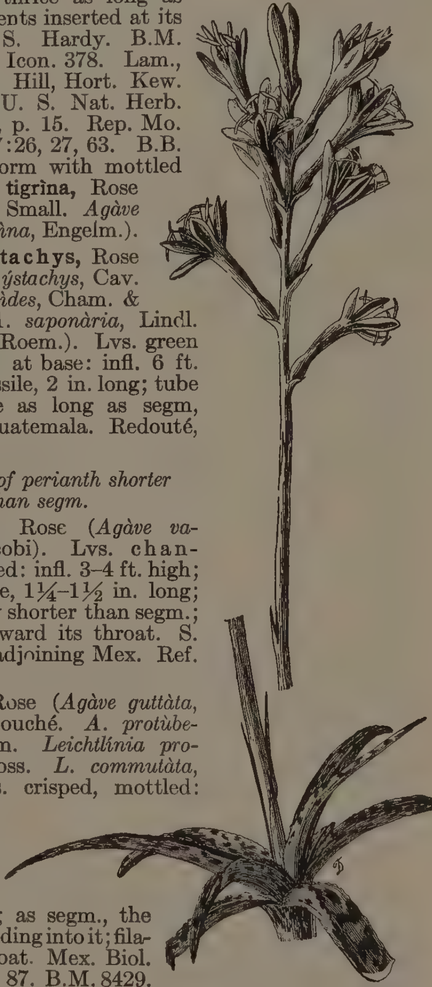
brachýstachys, Rose (*Agàve brachýstachys,* Cav. *A. polyanthoìdes,* Cham. & Schlecht. *A. saponària,* Lindl. *A. hùmilis,* Roem.). Lvs. green or reddened at base: infl. 6 ft. high: fls. sessile, 2 in. long; tube nearly twice as long as segm, Mex. and Guatemala. Redouté, Lil. 485.

CC. *Tube of perianth shorter than segm.*

variegàta, Rose (*Agàve variegàta,* Jacobi). Lvs. channeled, mottled: infl. 3–4 ft. high; fls. subsessile, 1¼–1½ in. long; tube slightly shorter than segm.; filaments toward its throat. S. Texas and adjoining Mex. Ref. Bot. 326.

guttàta, Rose (*Agàve guttàta,* Jacobi & Bouché. *A. protùberans,* Engelm. *Leichtlínia protùberans,* Ross. *L. commutàta,* Ross). Lvs. crisped, mottled: infl. 3 ft. high; fls. subsessile, 1–1¼ in. long; tube half as long as segm., the ovary protruding into it; filaments in throat. Mex. Biol. Cent. Amer. 87. B.M. 8429.

WILLIAM TRELEASE.



2319. **Manfreda maculosa.**

MANGEL-WURZEL. A race of beets with very large roots, grown for forage; usually shortened to mangel. Often called *Beta vulgaris* var. *macrorhiza.*

MANGÍFERA (from *mango,* common name of one species, and Latin, *to bear*). *Anacardiàceæ.* Tropical trees, of which *M. indica* is the only one well known horticulturally, and is cultivated throughout the tropics for its fruit, being naturalized in many regions. It is the mango of English-speaking countries, in its finer varieties one of the most delicious of all tropical fruits. Several other species also produce edible fruits, mostly, however, of indifferent value; their distribution is in nearly all cases limited. The Malay Archipelago is the home of nearly the entire genus, Malacca having a particularly large proportion of species. *M. indica* has been in cultivation since such a remote period that its exact origin is somewhat doubtful, but it has been considered by the best authorities to be indigenous to the Himalayan foothills of eastern India, extending possibly through Burma into the Malayan region.

Leaves alternate, petiolate, entire, coriaceous: fls. small, polygamous, in terminal panicles; calyx 4–5-partite; corolla 4–5-petaled; petals free or adnate to the disk, imbricate; stamens 1–5, rarely more, inserted just within the disk; in most species there is commonly only 1 fertile stamen, the remainder being more or less abortive or reduced to staminodes; ovary 1-celled, oblique, the style lateral: fr. a large fleshy drupe, with a compressed, fibrous stone.—A genus of about 30 species, natives of Trop. Asia. Several allied genera are of horticultural importance, notably Anacardium, which includes the cashew (*A. occidentale*), Spondias, of which several species are cultivated for their fruits, known commonly as hog-plum, Spanish plum, and so on, and Pistacia, which furnishes the pistacio nut; all tropical or subtropical in distribution. The genus Rhus, which includes the sumac and poison ivy, and is well represented in warm-temperate regions, is also a member of the same family.

índica, Linn. MANGO. Fig. 2320. A large tree, erect or spreading in habit, 30–90 ft. high, with oblong-lanceolate to elliptic lvs. 6–16 in. long, variable in breadth, glabrous, deep green, the margins sometimes undulate, apex commonly acute; petiole 1–4 in. long, swollen at the base: panicles a foot or more in length, pubescent, rarely glabrate; fls. yellowish or reddish, odorous, subsessile, staminate and hermaphrodite on the same panicle; sepals ovate-oblong, concave; petals twice as long as sepals, ovate, 3–5-ridged, the ridges orange; disk fleshy, 5-lobed; stamens 1 fertile, 4 reduced to staminodes of varying prominence; anthers purplish; ovary glabrous: fr. 2–6 in. or more in length, usually compressed laterally, greenish, yellowish or reddish in color. N. India, Burma, and possibly Malaya, as noted above. B.M. 4510. H.U. 3:193.

zeylánica, Hook. f. A tree, glabrous throughout: lvs. oblong-obovate to elliptic-lanceolate, usually rounded at the apex, 2–3½ in. long: panicle stout, longer than the lvs.; fls. on slender pedicels; sepals orbicular; petals short, elliptic-oblong, disk large; fertile stamen 1, with 6–8 staminodes; ovary slightly pubescent. Ceylon, up to elevations of 3,000 ft.—Closely approaches *M. indica,* but said by Hooker to differ in habit and foliage, the contracted panicle, fls. with longer pedicels, perfectly glabrous sepals, and short petals.

fœtida, Lour. BACHANG. AMBATJANG. A large tree, with elliptic-oblong to obovate lvs. 10–12 in. long, 3–4 in. broad, acute at base, acute to obtuse at apex; petiole stout, 1–1½ in. long: panicle large, stout, deep red; fls. subsessile; sepals ovate, obtuse; petals linear-lanceolate, reflexed, pink or red; stamens 5, 1 perfect, the rest shorter, imperfect; ovary glabrous, oblique, green, smooth, very fetid; flesh yellow, stone very fibrous. Distributed throughout the Malay Archipelago, where the fr. is eaten by the natives but is considered of very poor quality by Europeans.

odoràta, Griff. KUWINI. BUMBUM. A tree, glabrous throughout, or with panicles slightly pubescent: lvs. elliptic-lanceolate to oblong, 6–12 in. long, 2–4 in. broad, acute or acuminate; petiole stout, 1¼–1¾ in. long: panicle stout, green; fls. odorous; sepals ovate-oblong; petals linear-oblong, reflexed, greenish, suffused blood-red; perfect stamens sometimes 2, staminodes slender, capitate; ovary glabrous: fr. oblong, yellowish green, fetid, stone compressed, fibrous. A native of Malacca.—The fr. is said to be sweet, without any taste of turpentine.

cæsia, Jack. BINJAI. A large, stately tree, with stout branchlets: lvs. cuneate-obovate to elliptic, 6–16 in. long, 2½–3½ in. broad, somewhat glabrous; petiole ¼–1 in. long: panicle stout, much branched; fls. on short, stout pedicels; sepals broadly ovate, pubescent; petals erect, linear, concave, purplish; disk slightly lobed; perfect stamen 1, the imperfect ones reduced to teeth; style slender: fr. oblong-obovate. Malacca and other Malayan islands.—The frs. are eaten by the natives, but are said to be very poor.

verticillàta, Rob. Baúno. A large tree, 50 ft. or more in height: lvs. in whorls of 4, narrowly elliptic-obovate to obovate, glabrous, about 4–6 in. long, 2–3 in. broad; petiole 1–1½ in. long: panicles 8–12 in. long, tomentose; fls. on stout, tomentose pedicels; petals narrowly oblanceolate, bluish, margins inrolled; fertile stamen 1, staminodes 4, irregularly shaped: fr. oblong-oval to pyriform, 4½–6 in. long, yellowish green; stone large, very fibrous.—A recently described species from the southern Philippines. Its fr., which ripens in Aug. and Sept. is described by Wester as "very juicy, rich, subacid, quite aromatic, of excellent flavor, partaking of the flavor of the apricot and soursop combined." It is thought to be of considerable horticultural value.

The mango.

To millions of persons living within the tropics, the mango is of greater importance than is the apple to those of temperate North America. While this is especially true in southern Asia, where the mango has been grown from time immemorial, the last two centuries have seen the tree widely disseminated throughout the tropical regions of the New World, and playing an important rôle in the dietary of the inhabitants. In its finer varieties the mango is certainly worthy of a place among the world's best fruits; for beauty of coloring, delicate subtle aroma, and piquancy of taste it has few equals. Yet it must be remembered that it is only among the choicest varieties that these characters are found, and the inferior, fibrous seedlings, which have always constituted the larger part and are all too frequently considered by visitors to the American tropics as representative of the best to be found among mangoes, have little in common with some of the superb varieties of the Orient.

DeCandolle considered it probable that the mango has been in cultivation 4,000 years. At the present time it is found growing naturally in the tropical Himalayan region, from Kumaon to Bhutan, at altitudes of 1,000 to 3,000 feet, and in several other parts of India, while it is cultivated extensively throughout the peninsula, except in a few regions in which the climatic conditions are unfavorable. References to the mango in the early literature of India are said to be numerous, and it seems always to have been held in the highest esteem and even veneration; its flowers are employed in religious ceremonies, and in some places annual celebrations are held in its honor. In the fourteenth century, the Turkoman poet, Amir Khusru, wrote in Persian verse, "The mango is the pride of the garden, the choicest fruit of Hindustan; other fruits we are content to eat when ripe, but the mango is good in all stages of growth;" and the great Mughal emperor, Akbar, who reigned in the sixteenth century, planted near Darbhanga the famous Lakh Bagh, an orchard of 100,000 mango trees, some of which are said by Maries to remain to this day.

The dissemination of the mango throughout the tropical world seems to have been rather slow, considering the usefulness and importance of the fruit in India, but the difficulties in transporting seeds and plants in the early days, when travel by water was not rapid, must be remembered. Credit is probably due the Portuguese for carrying the mango to Africa, and later on to South America, where it is thought to have been first established in Brazil, but the date of its introduction to this continent is not definitely known. Within the eighteenth century it became scattered throughout the West Indies and on the mainland of Central America. At the present day it is found in nearly every tropical region of the globe, and in some places its culture has been extended into the subtropics; thus it is grown in the Canary Islands, Madeira, occasionally along the shores of the Mediterranean, in Australia, northern India and the Persian Gulf region, southern Brazil, and the southernmost part of the United States.

The English name "mango" is from the Portuguese "manga," which is itself considered an adaptation of the Tamil "man-kay" or "man-gay" which was formed by the earliest Portuguese settlers in India. Some writers consider that the Portuguese name had its origin in the Malay "mangga" or "mangka," but Rumphius traces the introduction of the latter into the Malay Archipelago from southern India, along with the fruit itself. In northern India the name is "am" or "amba," these forms or variations of them occurring in very early literature; in Sanskrit it is "amra." In the western hemisphere the common names are adaptations of the Portuguese "manga" (the tree "mangueira"); thus it is called in both English and Spanish "mango," in French "mangue" (the tree "manguier"), in Italian "mango," in German "mango" (the tree "mangobaum"), and in Dutch "mangga" (the tree "manggaboom").

2320. Fruits of the mango, Mangifera indica. (×⅕)

The tree is evergreen, and varies greatly in height and habit of growth. In India there are several kinds which are low-growing, almost prostrate in habit, but ordinarily the tree is erect, either with a broad, dome-shaped, umbrageous crown, or else with a tall, oval, more or less open crown and ascending branches. On deep rich soils the mango reaches immense proportions; one specimen with a trunk 25 feet in circumference and a spread of 125 feet has been measured in Bahia, Brazil. A height of 70 feet is not infrequently attained. Budded or grafted trees do not reach such large proportions, neither do seedlings on shallow soils.

The lanceolate deep green leaves are of leathery texture, varying in length from 6 to 16 inches or even more, and when crushed emit an odor of turpentine, pronounced in some varieties and almost lacking in others. Growth is made in periodic "flushes" from the terminal buds of the young branches; when a new flush makes its appearance its leaves are usually reddish or wine-colored, the color changing to green as the leaves mature. After the development of each flush there is usually a period of inactivity, following which another flush is made, each one varying in length from a few inches to a foot or more. The flowers, which are borne in large panicles a foot or more in length, produced in spring at the ends of the young branches, are yellowish or pinkish in color; there are sometimes 2,000 or even more on a single panicle, but only part of them are perfect, the mango being polygamous, i. e., producing on the same tree flowers in which both sexes are present and flowers which are unisexual. The staminate flowers greatly outnumber the perfect ones, as a general thing; there is, however, only one pollen-bearing stamen, the remaining four being abortive and represented by staminodes of varying prominence. The perfect flowers are easily distinguished from the staminate ones by the small obliquely round ovary, borne upon the swollen disk. The petals are ovate to lanceolate, commonly five in number.

In size and character of fruit the mango is extremely variable; there are varieties which are scarcely larger than a plum, and there are others whose fruits weigh as much as four or five pounds. The shape varies from round to long and slender, some of the commonest types being reniform, obliquely heart-shaped, oval, or elliptical. The skin is smooth, somewhat thicker than that of a peach, commonly yellow or greenish yellow in color, but in some varieties bright yellow overspread with scarlet or crimson, and of extremely beautiful appearance. Other types are uniformly pale lemon-yellow. The aroma is often delicious, spicy and tempting, and this added to the brilliant color, makes some of the finer varieties of the mango among the most attractive of all fruits. The stone is large, usually flattened, and in the ordinary seedling fruit covered with long, tough fibers, which extend from all sides into the yellow, juicy flesh. In the best grafted sorts there is no fiber and the fruit can be divided into halves, after making a longitudinal cut through the flesh, like a freestone peach.

The flavor, like that of many other tropical fruits, is difficult of description. Lady Brassey has likened it to a combination of apricot and pineapple, and others have compared it to the peach, yet neither of these comparisons conveys an accurate idea of the delicious piquancy and fragrance of a perfect mango, rich and sweet, yet never cloying, and overrunning with luscious juice. In seedlings there is often an objectionable taste of turpentine, especially in the skin; this, like the fiber, is done away with in the finer grafted varieties. However, it is sometimes true of the seedling fruit, as Jumelle remarks, that while "there are those who do not like it because it smells of turpentine, there are others who come to like turpentine because it reminds them of the mango."

The mango is preëminently a dessert fruit, yet it lends itself to an infinite variety of uses, chief among which, in India, is the manufacture of chutneys and preserves. Mango chutney, of which there are numerous kinds, such as Major Grey's, Colonel Skinner's, Lucknow, and Bengal Club, is exported from India in considerable quantities. The unripe fruit is used in its manufacture, together with various other ingredients, principally spices. The unripe fruit is also used to prepare a dish known in India as "mango phul," a sort of custard made with milk and sugar. The ripe pulp, properly spiced, is dried in the sun to form thin cakes known as ambsath, a product which is, according to Woodrow, "the special solace and delight of Indian students in foreign countries." In Cuba and other parts of tropical America, the fruit is extensively used for the manufacture of jams and preserves. Exquisite sherbets and iced drinks are made from it, the Cubans and Brazilians being especially skilful in preparing them. In recent years, canning factories have been started in India for the purpose of preserving the fruit in the same manner as peaches and pears are preserved in this country. There are varieties of the mango especially suited for culinary use, and others preferable as dessert fruits, just as with the more important temperate fruits.

In the United States, mango-culture has, in recent years, attracted considerable attention in southern Florida, where extensive experiments have been made with varieties from all parts of the world. In 1901 it was found that the tree could be successfully budded, and nursery stock began to be produced in sufficient quantities to permit of orchard plantings. The most extensive groves are found in the vicinity of Miami, on the lower east coast, but there are also numerous small plantations as far north as Palm Beach on the east coast, and at Fort Myers and other points on the west coast, extending as far north as Tampa Bay, where the trees are sometimes injured by frost, but nevertheless grow and fruit fairly well, especially in the vicinity of St. Petersburg. Florida has supplied nursery stock to plant several young groves in Cuba, the Isle of Pines, and Porto Rico as well.

In California, the culture of the mango is limited to the warmest locations, but fruit has been successfully produced at Sierra Madre, Santa Ana, Hollywood, and Santa Barbara. From past experiments, it appears that the tree is much better suited to the so-called frostless districts some distance from the seacoast than to such localities as Santa Barbara, for the reason that near the ocean there is not sufficient heat during the summer months to ripen the fruit. The dry climate of California seems to stunt the tree, and it develops much less rapidly than in the tropics, but with abundant irrigation it has made fairly good growth, especially in the deep sandy loam of some of the foothill regions. As to frost, the plants, when young, are easily injured by temperatures lower than freezing, but when they have attained a few years' growth they will withstand temperatures as low as 27° or 28°, provided they are not of long duration, without serious injury. Protection should be given wherever possible

Cultivation of the mango.

In regard to soil, the mango does not seem to be very particular, but respecting climate it is much more exacting. Deep rich soils, like many of those found in Porto Rico and Cuba, produce a more rapid growth and greater ultimate dimensions, but the shallow sandy soils, underlaid with soft limestone, which are found on the lower east coast of Florida, have so far proved satisfactory, the mango requiring less fertilizer under such conditions than the avocado or some other tropical fruits. In India some of the best mango districts have a deep rich alluvial loam, somewhat sandy in nature, and this can probably be considered the best of all mango soils.

Granting that the mango is grown in a region free from injurious frosts, the most important climatic factor is the amount of rainfall, especially in regard to the season in which most of it occurs. In general it may be said that the mango produces the largest crops and most brilliantly colored fruit in regions in which there is a well-defined dry season corresponding to the blooming and ripening season; damp, cloudy weather while the trees are in bloom, even without any actual precipitation, is very prejudicial, and it has been thoroughly demonstrated in Florida that the best crops are produced in seasons when the weather is dry and sunny during the blossoming period. Moist weather favors the spread of blossom-blight or anthracnose (*Colletotrichum gleosporioides*), a fungous disease that sometimes destroys all of the flowers. Many seedling mangoes, as well as some grafted varieties, often produce a second crop of flowers if the first is destroyed. Trees in Cuba have even been known to flower four times; on the other hand, some mangoes bloom only once in a season. Spraying with bordeaux mixture, made in the proportion of five pounds of copper sulfate and five pounds of unslaked lime to fifty gallons of water, is often employed to prevent the blighting of the flowers, several applications being given while the trees are in bloom, commencing with the appearance of the first flower-buds. It is also well to spray occasionally during the time the fruits are developing, to prevent infection which may lead to rapid decay when the fruits are picked and shipped to market.

Regions where the annual precipitation is from 30 to 50 inches, and where a very small proportion of this occurs during the flowering season, seem to be ideal for the mango. Even in such regions, however, difficulty is often experienced in forcing some varieties to bloom, the mango showing a marked tendency toward irregularity in its fruiting habits. In tropical countries, various methods have been devised to encourage the formation of flower-buds and setting of fruits, such as partly girdling the trunk, hacking the trunk, severe root-pruning, placing common salt around the tree, and smoking the tree during the blooming period by keeping a smudge burning under its widespreading branches. Most of these methods are out of harmony with modern horticultural practice, and of doubtful advisability, but it appears that something should be done in autumn to check vegetative growth and encourage the formation of flower-buds. Withholding all fertilizers at this season and moderate pruning of the roots may be suggested as of possible value.

In planting out young budded trees in orchard form, they should be set at least 30 to 35 feet apart, in holes prepared in advance. Late spring—April and May—is considered the best time for planting in southern Florida. During the first few years well-rotted stable-manure or sheep-manure can be used to encourage growth, but it should not be applied in large quantities, and after the trees reach bearing age the greatest care is necessary in applying fertilizers. For Cuban soils a fertilizer containing 3 per cent nitrogen, 10 per cent phosphoric acid, and 10 per cent potash has been recommended, fifteen to twenty-five pounds a year being given to mature trees. No fertilizers should be applied in fall or winter or during the time the trees are in flower. Little pruning is usually given the mango, though the trees may require some attention while young to encourage the formation of a symmetrical, well-branched head, which should not, however, be too dense. Grafted trees are usually spreading in form, and should be encouraged to remain so, especially in regions subject to occasional hurricanes.

Insect pests of the mango.

Of the insect pests attacking the mango, the fruit-flies (Trypetidæ) rank first in importance. Belonging to this family are the Mediterranean fruit-fly (*Ceratitis capitata*) which has so adversely affected the fruit-growing interests of Hawaii, the Queensland fruit-fly (*Dacus tryoni*), the mango fruit-fly (*Dacus ferrugineus*), the Mexican fruit-fly (*Anastrepha ludens*), which has become troublesome in Porto Rico. The females of these flies insert their eggs into the flesh of the fruit by means of a most efficient ovipositor, and the larvæ infest the fruit, rendering it unfit for human consumption, and in cases leading to premature ripening and decay. Control is difficult; the sweetened arsenical sprays have met with varied success, and natural control by parasites is now receiving attention. In India, the mango hopper (various species of Idiocerus) and the mango weevil (*Cryptorhynchus mangiferæ*), which latter has now been reported as doing considerable damage in Hawaii, are of importance as pests. Cleanliness in the grove by way of periodically gathering drops will prevent pupation of the fruit-flies and weevil and considerably reduce their numbers. In Florida, red-spider and thrips are responsible for extensive injury to foliage, leading to disturbances of the general health of the tree; but contact sprays, e. g., lime-sulfur or nicotine, properly applied, will effect complete eradication. Numerous scale insects have become injurious in certain localities and may be controlled by the use of kerosene emulsion, but the desirability of natural enemies such as the coccinelid beetles being present in the orchard must not be forgotten. A large bark-boring beetle (*Plocæderus ruficornis*) has been responsible for much damage to trees in the Philippines.

The mango crop.

The age at which budded or grafted mango trees will come into bearing depends upon the variety and upon several other factors, but they cannot as a rule be expected to produce fruit under three or four years from the time of planting, and in the case of some varieties this time is considerably extended. As to yield, some of the smaller-fruited varieties will produce several thousand mangoes in a single crop, when the tree is of mature size, while Mulgoba and other large mangoes are doing well when they produce a few hundred. Experience has been that the crop varies greatly in different seasons, and it has been impossible to fix a certain quantity as the average yield of any one variety. So much is dependent upon the weather at the time of flowering, with the consequent setting or dropping of flowers, that irregularities in bearing are all too common. Some mangoes, however, such as Cambodiana and Sandersha, have shown themselves much more dependable in this regard than others, and are especially valuable for this reason.

The fruit is picked when fully mature, but before it has commenced to soften on the tree. If allowed to remain on the tree too long, it is sometimes found that the flesh immediately surrounding the seed is unpleasant to the taste and of a peculiar gelatinous consistency. Shears should be used for picking, leaving a short section of the stem attached to the base of the fruit; this will dry up and fall off in a few days, but if the fruit is pulled from the tree the sap exudes freely from the stem end, disfiguring the surface.

The usual carrier used for mangoes in Florida is the tomato-crate, holding six small baskets. Each basket will contain six mangoes of good size, making thirty-six to the crate. The individual fruits are wrapped in tissue paper before packing, and excelsior is used above and below them as a cushion. Mangoes are shipped from south Florida to New York, Boston and Chicago, without difficulty, nearly always arriving in good condition if they were picked at the proper time. In recent years, the south Florida growers have received $9 a crate for Mulgobas. The season during which they are shipped from Florida extends from late July until the latter part of August. Some varieties begin to ripen early in July, while the later ones, such as Sandersha, extend the season until the end of September.

Propagation of mangoes.

The simplest vegetative method, and the one extensively used in India, is that known as inarching or grafting by approach. While this is the most certain of all methods, it is too slow and laborious to meet the demands of present-day nurserymen, when more expeditious means can be found. Consequently budding is rapidly taking the place of inarching in this country, and though requiring considerably more skill it has proven entirely practicable for nursery work.

Inarching is performed between a large tree of the variety which it is desired to perpetuate and young seedlings grown in pots or boxes. The seedlings are ready for inarching when ten months to a year old;

they should have stems slightly less than ½ inch in diameter. An easily accessible branch on the parent tree, of the same diameter as the stem of the seedling, should be selected for the cion, and the seedling in its pot placed upon a stage or support where the cion can be brought into close contact with it. The juncture where the inarch is made should be about 6 inches from the base of the seedling, and about a foot from the tip of the cion, which should be as straight and vigorous as possible. A thin slice of bark and wood about 3 inches long is removed from one side of the seedling stock, and a similar slice from one side of the cion; the cut surfaces are then bound closely together with waxed tape, or with raffia or soft string, and afterward covered with wax to exclude the air. Several months are required for a union to be effected, after which the top of the seedling is removed just above the juncture of stock and cion, and the cion is severed from the parent tree just below the juncture. Inarching is usually done in India at the beginning of the rainy season, but it can be successfully practised at almost any time of the year.

Seedling stocks for budding or grafting are easily grown. After removing the husk, the seed is planted in a 5-inch pot and barely covered with soil. As soon as germination takes place, the plants should be watched to see that not more than one shoot is allowed to develop; some mangoes are poly-embryonic and will produce six or eight shoots from a single seed. When the young plants are well started, which in Florida should be by early fall if the seeds were planted in midsummer, they may be set out in the field in nursery rows 2 feet apart, the plants 1 foot apart in the rows, and allowed to remain there until after they are budded. Field budding has been found much more satisfactory than budding in pots.

Several very distinct races of mangoes are known in cultivation, and as yet practically nothing has been done to determine which of these are of the greatest value as stocks, although there is every indication that this is an important question. In addition, some of the numerous other species of Mangifera may be of value for this purpose. As a general thing seeds of any variety are used, including those of the common "turpentine" mangoes, as they are called, which can usually be obtained in quantity at a very low price. The seeds should be planted as soon as possible after their removal from the fruit, as they do not retain their viability for many weeks. They are rather difficult to transport through the mails, especially when sent to distant countries.

The proper time for budding is when the plants have attained a diameter of stem as great as that of a lead pencil, or greater, and are just coming into flush, i.e., when the terminal bud is just starting to push out new growth. The budwood, which should be cut from vigorous, healthy trees, should be round, straight, smooth, and preferably of the second flush from the ends of the branches, the most recent flush of growth being discarded. The wood should be as dormant as possible, and the end of the branch from which it is taken should never show the wine-colored young leaves which are indicative of active growth. It is well to have wood which has hardened up sufficiently to have lost its bright green color and assumed a grayish cast.

The buds should be cut 1 to 1½ inches in length, with a straight, sliding motion of the knife, aiming, if possible, to keep the blade parallel with the budstick. A thin, keen blade is essential. The incision is made in the stock in the form of a T or an inverted T, exactly as in budding citrous trees, and the bud is inserted without any more pressure than necessary. A strip of waxed tape is then used to bind it firmly in place. Cheap muslin is used for making the tape; after being torn into strips about 6 inches wide it is made into rolls 1 inch in diameter and boiled in a mixture of one pound beeswax and one-fourth pound rosin.

Edward Simmonds, who has worked out the budding of the mango in south Florida, considers April and May the most propitious months for inserting the buds. In strictly tropical regions the work can probably be done at any time of the year when the stock plants are in proper condition.

At the expiration of three to four weeks, the top of the stock is lopped, providing the bud shows signs of having formed a union; lopping should not be close to the bud, as this has been found to be dangerous.

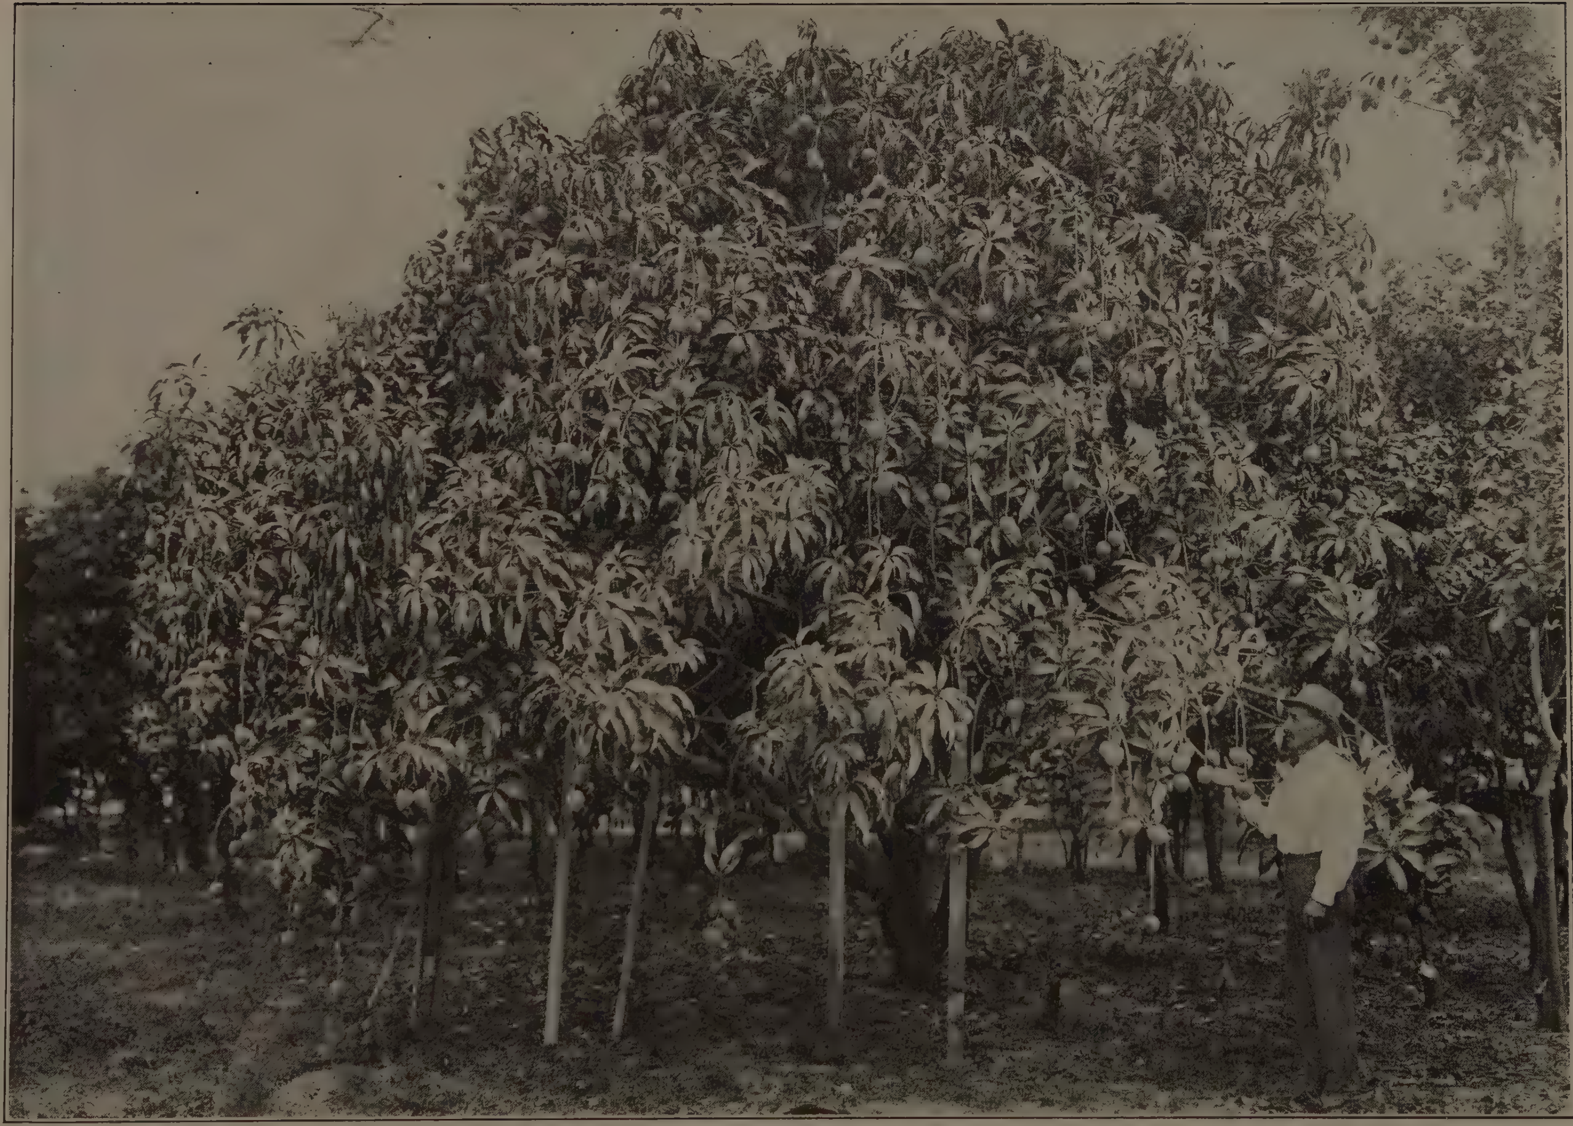
Large seedling trees are often worked over to choice varieties by cutting off several of the main branches a short distance from the trunk, and allowing a number of sprouts to come out. When these have reached the proper size they can be budded in the same manner as seedlings.

Races, types and varieties of mangoes.

In different parts of the world several very distinct races of mangoes are found, which tend to reproduce their racial characteristics when grown from seed, though showing minor variations in form of fruit and other characters. One of the best defined races is that from the Philippines, which appears to be closely allied, if not identical, with the Cambodiana from Indo-China; several more or less distinct seedling types of this race are known in the Philippines, notably Pahutan, Carabao, and Pico, and among these, in turn, are to be found slightly differing forms which when propagated by budding or grafting would constitute horticultural varieties. The Philippine race, which is polyembryonic, was brought to tropical America at an early day, doubtless by the Spaniards, and is the favorite in Mexico, where its seedlings are generally called "Manila mangoes," and in Cuba, where it goes by the name of "Filipino." In India, most varieties appear to belong to a mono-embryonic race which breaks up into more or less well-defined classes or types, of which there are in turn numerous horticultural varieties propagated vegetatively; thus of the well-known Bombay type, or group, as it has been called by some writers, there are several varieties, as also of the Langra, Malda and other types. In Jamaica the polyembryonic race known as No. 11 has become very popular because of the fact that it reproduces itself very closely when grown from seed (which most mono-embryonic mangoes fail to do) and has maintained its good quality for considerably over 100 years; it appears to be very closely allied to the Manga da Rosa of Brazil, and probably has other allies in the region from which it came. The relationships of the various races and types of mangoes has not as yet been thoroughly studied, and a good classification is lacking.

Of horticultural varieties there is an infinite and bewildering number, especially in India, where it appears to have been the custom to name almost every tree that produced fruit of superior quality; this has led to confusion and synonymy. One of the earliest Indian authorities on the mango, Maries, reported a collection of 500 varieties near Darbhanga, while large numbers of named varieties have been briefly described from many localities by various writers, bringing the number of published varietal names well up toward a thousand. Only a very limited number of these, however, such as the famous Alfonso or Alphonse of Bombay, have become well known and generally recognized.

The best Indian mangoes are probably not equaled in flavor and quality anywhere else in the world, though some travelers have professed a preference for the Philippine types, which are, indeed, very delicious. But the process of selection which has been going on in India for centuries, and the perpetuation of the best seedlings by inarching, has led to the existence of



LXVIII. A Paheri mango tree in fruit.—Florida.

remarkably fine mangoes in several parts of the Indian peninsula, most notably, perhaps, in the vicinity of Bombay, at Poona, at the Portuguese colony of Goa (where, in fact, it is thought by some writers that vegetative propagation of the mango was first introduced, the Portuguese having been instrumental in establishing this method which has meant so much to Indian horticulture), at Madras on the eastern coast, and in several districts toward the northern part of the peninsula, such as Malda, Darbhanga, Saharanpur, and Lucknow.

Grafted Indian varieties were first introduced to the United States in 1889, when the Department of Agriculture obtained from Bombay a collection of five kinds, which were placed with fruit-growers on Lake Worth, Florida, for trial. In the freeze of February, 1895, all save one of the trees perished; the surviving tree, a Mulgoba, came into bearing in 1898, and the superior quality of its fruit gave a marked stimulus to the cultivation of the mango in this country, resulting in the introduction of numerous other Indian varieties of reputed excellence. These have been added to by introductions from Indo-China, Ceylon, the Philippines, and other regions where good mangoes are grown. Among the best now grown in Florida and the West Indies are the following:

Mulgoba, which in delicate, aromatic flavor, smoothness and fineness of pulp, freedom from fiber, and attractiveness, must be placed in the very first rank. A good specimen will weigh about one pound, is broadly oval in shape, plump, clear yellow in color, blushed around the base with crimson-scarlet. Its season in Florida extends from July to the first of September. Unfortunately, it has proved irregular in its fruiting habits, and does not usually come into bearing as young as some other varieties. In some seasons considerable quantities of the fruit have been shipped from south Florida to northern markets, the growers realizing $9 a crate of thirty-six fruits.

Haden is a fruit very similar in general characteristics to Mulgoba, of which it is believed to be a seedling. It originated at Cocoanut Grove, Florida. Good specimens weigh sixteen to twenty ounces, and are highly colored. The flesh is scarcely as smooth as that of Mulgoba, and the flavor not quite so piquant, but nevertheless very good. Its season corresponds to that of Mulgoba.

Paheri (probably synonymous with Pairi, which is now considered by the best Indian authorities the correct spelling of the name) was introduced from India in 1902, and has been found of excellent quality in Florida. Near Bombay, India, it is considered the finest flavored of all mangoes, but because of the superior keeping qualities of Alfonso the latter is preferred commercially. It is a fruit of about twelve ounces in weight, oval, plump, orange-yellow in color, blushed with scarlet on the cheek, the flesh deep orange, very juicy, and of rich, spicy flavor. It ripens in Florida in July and August.

Amini is a smaller fruit than any of the above, averaging six or eight ounces in weight; in form it is oblong-ovate, in color almost identical with Mulgoba. The aroma is remarkably penetrating and agreeable, while the flavor is unusually spicy. The tree is more productive than some of the larger varieties, and seems slightly more resistant to blight. It is a little earlier than Paheri in season.

Cambodiana, mentioned above as a polyembryonic seedling race, was introduced to Florida about 1902, and several of its seedlings have been propagated by budding. While they cannot be considered equal in flavor and quality to the best of the Indian mangoes, the tree is much more regular in its fruiting habits. The race is characterized by an elongated, compressed fruit, frequently rather sharp at the apex, and of a light yellow or greenish yellow color. The flesh is yellow, juicy, of a pleasant flavor, but lacking the richness of Mulgoba or other good Indian mangoes, while the fiber is somewhat more abundant. In season it is a little earlier than Mulgoba.

Bennett is a select strain of Alfonso or Alphonse from Bombay which has been grown for several years in Florida. In quality it ranks very high, but it has been somewhat at a disadvantage in the markets because of its rather dull orange-yellow color. It is a fruit of about one pound in weight, oval to somewhat cordate in form, plump, with orange-yellow flesh and a seed almost entirely free from fiber. The season of ripening is July and August.

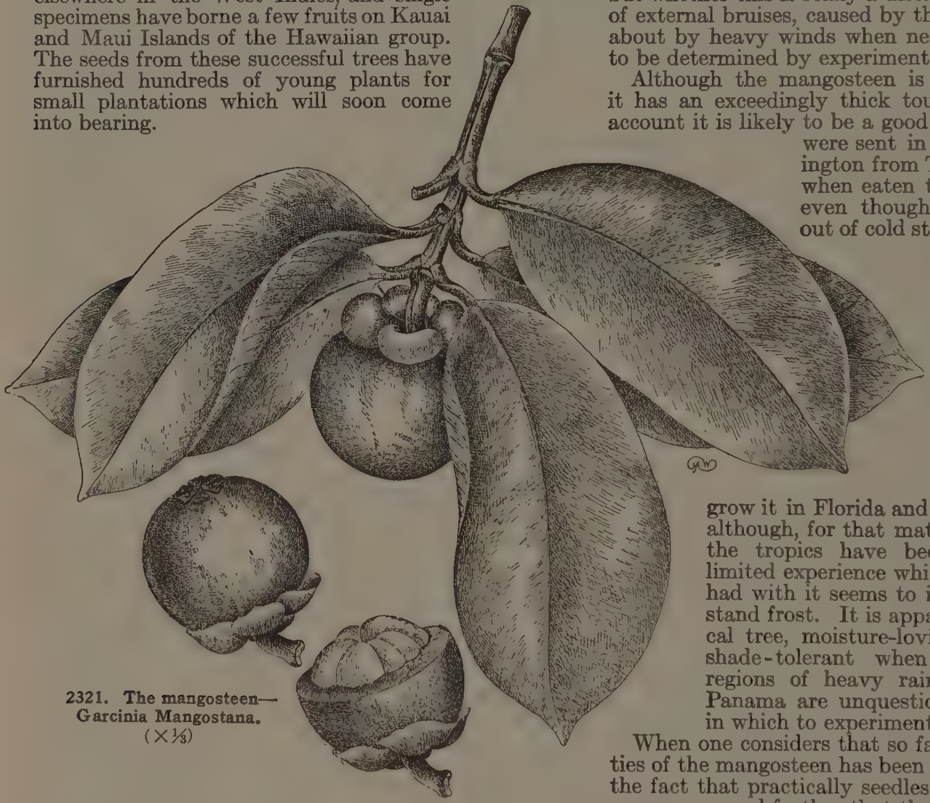
Sandersha is a very large fruit, frequently two pounds in weight, of elongated, somewhat curved form, orange-yellow in color. The flesh is free from fiber, and, when properly ripened, of pleasant flavor, though a trifle coarser than the best varieties. It is excellent for cooking, and because of its regularity in bearing is considered valuable. It ripens very late, beginning in late August and extending through September. F. W. Popenoe.

MANGOSTEEN (Fig. 2321), *Garcinia Mangostana* (which see), is a handsome fruit-tree 25 to 30 feet high, of compact growth, regular in outline, with dense, dark green foliage which reminds one slightly of the rubber tree. It grows slowly and comes into fruit late, not before eight or nine years of age. Its flowers are 1½ inches across with four rose-pink fleshy petals and a large superior ovary. In Ceylon the trees bloom twice, once in August, producing fruits which ripen in January, and again in January, producing fruits in July and August. In Trinidad the fruiting seasons are July and October. The January crop in Ceylon is a light one, however, not amounting to over 100 fruits to a tree, whereas the August crop amounts in good years to 500 or 600 fruits, according to Wright, of Mirigama, Ceylon. The fruits are borne from buds produced near the tips of short branches mainly on the outside of the tree, and are striking by reason of their persistent large leathery light green calyx-lobes.

This delicious fruit is about the size of a mandarin orange, round and slightly flattened at each end, with a smooth, thick rind, rich red-purple in color, with here and there a bright, hardened drop of the yellow juice which marks some injury to the rind when it was young. As these mangosteens are sold in the Dutch East Indies,—heaped up on fruit-baskets, or made into long regular bunches with thin strips of braided bamboo,—they are as strikingly handsome as anything of the kind could well be, but it is only when the fruit is opened that its real beauty is seen. The rind is thick and tough and in order to get at the pulp inside, it requires a circular cut with a sharp knife to lift the top half off like a cap, exposing the white segments, five, six or seven in number, lying loose in the cup. The cut surface of the rind is of a most delicate pink color and is studded with small yellow points formed by the drops of exuding juice. As one lifts out of this cup, one by one, the delicate segments, which are the size and shape of those of a mandarin orange, the light pink sides of the cup and the veins of white and yellow embedded in it are visible. The separate segments are between snow-white and ivory in color and are covered with a delicate network of fibers, and the side of each segment where it presses against its neighbor is translucent and slightly tinged with pale green. The texture of the mangosteen pulp much resembles that of a well-ripened plum, only it is so delicate that it melts in the mouth like a bit of ice-cream. The flavor is quite indescribably delicious. There is nothing to mar the perfection of this fruit, unless it be that the juice from the rind forms an indelible stain on a white napkin. Even the seeds are partly or wholly lacking and when present, are very thin and small.

Notwithstanding the fact that it has for at least two generations been called the "queen of fruits" and that Queen Victoria offered a prize of ten pounds for the first fruits which should be brought to her from India, there appears to be nowhere in existence what would be called a large orchard of mangosteens. It is hard to understand why the culture of so delicious a fruit as the mangosteen should not have been better understood by horticulturists.

In the Dutch East Indies, Java and Sumatra in particular, it is planted by the natives in their kampongs as a dooryard tree. In Malacca and the Straits Settlements there are a few small orchard plantings owned chiefly by the Chinese. In Burliar Gardens in the Nilgiri Hills of Madras Presidency, British India, a few trees are growing. The native chiefs of the Sulu Archipelago have scattered plantings of mangosteen trees. A few small plantings have been made in Ceylon, notably a small orchard at Mirigama. Father D'Adran, a noted Bishop of Cochin-China, established an orchard of 300 to 400 trees at Lai Thiou not far from Saigon. Trees of it have grown and fruited in the Botanic Gardens of Jamaica, Trinidad, Dominica, and probably elsewhere in the West Indies, and single specimens have borne a few fruits on Kauai and Maui Islands of the Hawaiian group. The seeds from these successful trees have furnished hundreds of young plants for small plantations which will soon come into bearing.



2321. The mangosteen—Garcinia Mangostana. (×⅓)

The reason for this very inadequate distribution of so remarkable a domesticated fruit-tree seems to lie in the difficulty which the young plants seem to have in establishing themselves. If the seedlings are not shaded, the first pair of young leaves is generally injured and the plants stunted or even killed outright. It is thought that horticulturists do not yet understand the root-system of the magnosteen and that when it is understood, a vast extension of the culture of this fruit will take place. This may come about through the use of stocks which are less particular in their soil-requirements. Geo. Oliver's experiments have proved that the mangosteen can be successfully inarched upon a number of the related species of the same genus. On *Garcinia xanthochymus*, which is a much more vigorous tree and grows on many types of soil, and is apparently quite at home in Hawaii, Natal, Madeira, Cuba, and many other localities in the subtropics it seems to grow successfully. As 169 species of garcinias have already been described, the probability is great of finding a suitable stock for the mangosteen.

The best orchards of mangosteen in Ceylon and Singapore have been established on soils characterized by a high clay content, combined with a large percentage of coarse material, with a very small amount of silt, and upon locations where the water-table comes to within 6 feet of the surface. The impression is current that the mangosteen requires a wet but well-drained soil and a very humid atmosphere. While the former statement appears to be true, the latter is not so, for the tree which has fruited on the Island of Kauai is in a dry but irrigated part of that island, with only 6 inches of rainfall, where it has to be irrigated twice a month.

The diseases of the mangosteen are not yet known. It is likely to have its own specific diseases, and when transplanted to new environments, may be attacked by new parasites. Fruits are frequently found with drops of yellow gamboge inside which make them unpalatable, but whether this is really a disease or merely the result of external bruises, caused by the fruits being knocked about by heavy winds when nearly mature, will have to be determined by experiment.

Although the mangosteen is a very delicate fruit, it has an exceedingly thick tough rind, and on this account it is likely to be a good shipper. Fruits which were sent in cold storage to Washington from Trinidad were excellent when eaten twenty-one days later, even though they had then been out of cold storage over a week. The fact that when one of a shipment of fruits decays, its rind hardens instead of becoming soft, is an important point in its favor.

Just how much cold the mangosteen can stand has not yet been determined. Repeated attempts to grow it in Florida and California have failed, although, for that matter, many attempts in the tropics have been unsuccessful. The limited experience which horticulturists have had with it seems to indicate that it will not stand frost. It is apparently a strictly tropical tree, moisture-loving and more or less shade-tolerant when young, adapted to regions of heavy rainfall; Porto Rico and Panama are unquestionably excellent places in which to experiment with its culture.

When one considers that so far no selection of varieties of the mangosteen has been made, notwithstanding the fact that practically seedless fruits are of frequent occurrence, and further that the tree belongs to a large genus of fruit-bearing trees, at least fifteen of which are known to bear edible fruit, some of them as large as small melons, and that these are scattered in Australia, the Malay region, South China, Africa, Brazil, and Central America, some of them being able to withstand light frosts, it becomes evident that in the development and breeding of the mangosteen and in the discovery of a suitable stock for it, there lies a most promising field for horticultural research.

David Fairchild.

MANGROVE. A name applied to certain small trees that grow along tropical and semi-tropical seacoasts and produce many trunks or rooting shoots whereby the plant holds its place or marches on tide-flats. The name is usually restricted to *Rhizophora*

Mangle (*Rhizophoraceæ*), which grows in tropical America and the seacoasts of Florida. The black mangrove is *Avicennia nitida* (*Verbenaceæ*) of the Gulf coast and tropical America; and the name mangrove is applied to species of this genus in other parts of the world. For an account of the curious propagation of the Rhizophora, see page 980, "Cyclopedia of American Horticulture."

MANICÀRIA (name derived from the word for *glove*, because of the spathe). *Palmàceæ*. Two or 3 species, or perhaps only 1, in Trop. S. Amer., little cult., allied to Geonoma. They are robust unarmed palms with more or less pinnatisect or entire lvs.: fls. large, rose-ochroleucous, heavy-scented, on many branching tomentose spadices: fr. very large. *M. saccífera*, Gaertn., has lvs. simple or split with age, dentate, 30 ft. long and 4–5 ft. broad, transversely furrowed, crowning an erect deeply ringed trunk: fls. of both sexes on the same spadix, the latter 3–4 ft. long: fr. 3-lobed. Lower Amazon and elsewhere. A striking palm with its immense simple lvs.

MÁNIHOT (native Brazilian name). *Euphorbiàceæ*. Tropical trees and shrubs cultivated as ornamentals and for important economic products.

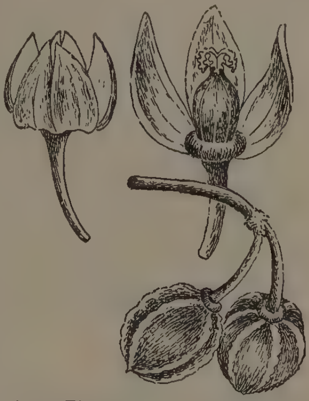
Usually glaucous and glabrous or nearly so: juice milky: lvs. alternate, entire to lobed or sometimes almost palmate: fls. large for the family, monœcious, in terminal or axillary racemes or panicles, apetalous; sepals united, at least at the base, imbricate, often petaloid; stamens 10; ovules 1 in each of the 3 cells; seeds carunculate.—About 130 species, all American and mostly in Brazil. Related to Jatropha and Ricinus. Although the plan of the infl. is different, several species of Manihot and Jatropha are otherwise so similar that they have been placed first in one genus and then in the other. Monogr. by Pax, in Engler's Pflanzenreich, hft. 44 (1910).

The cassava plant, *M. utilissima*, has been cultivated as a food plant since prehistoric times by the natives of Brazil. There are many varieties in cultivation and these are not known in the wild state. The plant is a perennial shrub in the tropics, and resembles somewhat the castor bean. The abundant starch in the large fleshy roots which grow in a cluster at the base of the stem gives it its food value. It is used in various ways as food, including the manufacture of tapioca, Brazilian arrow-root, and the like.

The roots contain more or less hydrocyanic acid which is often sufficient to render them deadly poisonous in the raw state. It is rendered harmless by heating or is pressed out with the juice in preparing the roots for food. The more poisonous varieties are generally known as bitter cassava, those with less of the acid as sweet cassava, but the amount of the poison varies with seasons and other conditions. Varieties of *M. dulcis* var. *Aipi* are also grown as sweet cassava in the tropics but are generally not very productive. *M. carthaginensis* is also sometimes used as cassava.

Cassava is grown in some of the warmer parts of the United States chiefly as a stock feed. It does best in light, but rich sandy soil. It is propagated by cuttings. Just before frost the more mature parts of the canes are cut and buried till spring and then cut into 4- to 6-inch pieces and planted 4 feet each way. The cultivation is similar to corn. In tropical countries the cuttings may be made and planted at any time. Some varieties, especially early maturing ones, may be grown from seed. The roots are left in the ground till used, as they decay quickly when harvested. The yield is from six to ten tons of roots to an acre, or even more. For further information on cassava, see "Cyclopedia of Agriculture," Vol. II, p. 227, and Farmers' Bulletin, United States Department of Agriculture, No. 167.

Manihot Glaziovii and other species have long been utilized for rubber in the wild state in Brazil. Some years ago this species was planted extensively in various tropical lands out of its natural habitat, the general result being a low yield of rubber and disastrous failure of the enterprise. In recent years, plantations under proper conditions have given much better results. This is the chief source of the ceara rubber, so called from the town of Ceara in Brazil. Other species are also worked for rubber in the native woods of Brazil. *M. dichotoma* and *M. piauhyensis* are also being grown in rubber plantations with success. All the ceara rubber species grow in dry situations with little summer rainfall. *M. piauhyensis* is more shrubby and adapted to light sandy land and *M. dichotoma* to rough heavier soil. *M. heptaphylla* is also grown to some extent for rubber on light soil.



2322. Flowers and fruit of Manihot utilissima. (Enlarged)

The ceara rubber trees are grown from seed, but may be raised from cuttings. The seed is planted about 1 inch deep in good soil and kept moist till the seedlings are well established. The germination is slow and irregular, taking from three weeks to six months. Filing the seed-coat to hasten germination has been tried but often encourages decay. The young plants are cut back and transplanted into the field after the stem has hardened. They grow rapidly, the taller species like *M. Glaziovii*, reaching 16 feet in ten months. The smaller ones may yield a full crop in four years after planting. (See Ule. Notizbl. Bot. Garden, Berlin, 5, 1908.)

Some species of manihot are occasionally grown in greenhouses mostly for the tropical effect of the foliage. They are grown in light but rich soil and do best in a dry room. They are propagated easily from seeds but are usually grown from cuttings of young but firm wood in sandy peat under glass with bottom heat.

A. *Bracts over 1 in. long, ovate to broad-lanceolate: calyx glabrous, ¾in. long: shrubs or small trees.*

piauhyénsis, Ule. Tree, 6–20 ft. high: lvs. 5–7-parted, practically to the base, the lobes obovate-cuneate, obtuse, entire, mucronate, somewhat pubescent, 3–4 in. long: fls. racemose: caps. wing-angled. S. Brazil.—Cult. for rubber.

heptaphýlla, Ule. Tree, 6–20 ft. high: lvs. 3–7-parted almost to the base, the lobes obovate-oblanceolate, some of them pandurately or sinuately 1–2-lobed near the apex, 4–5 in. long, acuminate, mucronate: fls. in short racemes: caps. subterete, not wing-angled. S. Brazil.—Cult. for rubber.

AA. *Bracts much smaller, usually narrower.*

B. *Lvs. not peltate.*

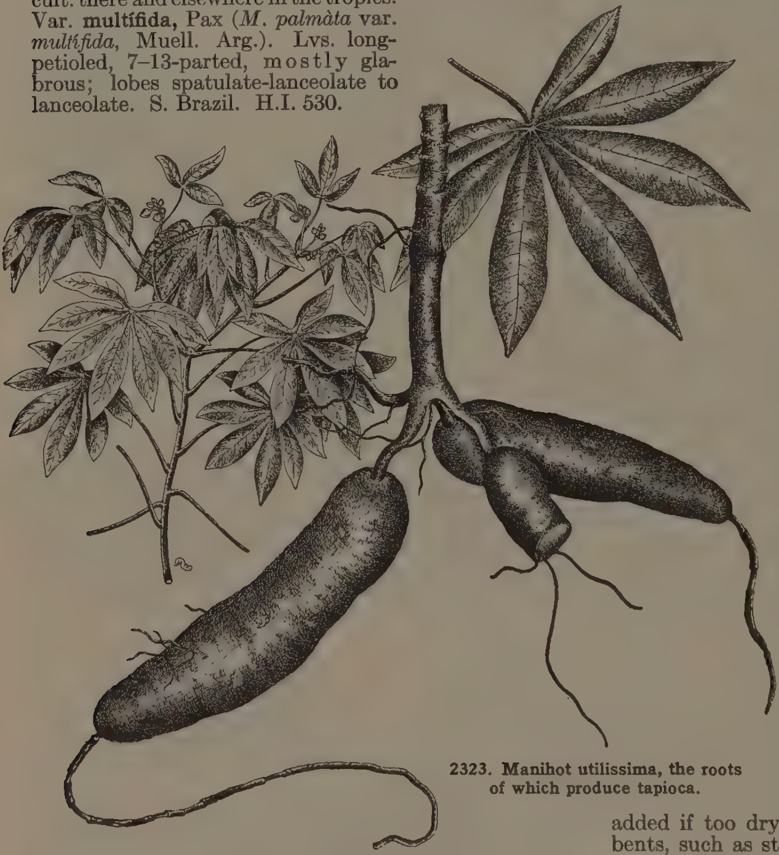
C. *Lf.-lobes entire.*

palmàta, Muell. Arg. (*Játropha palmàta*, Vell.). Shrubby: lvs. deeply 5–11-parted, glabrous, base cordate; lobes of leaves, 3–5 in. long, lanceolate, acuminate; stipules small, deciduous: fls. racemose to sub-paniculate; calyx ¾in. long, glabrous: caps. not wing-angled. S. Brazil.

utilíssima, Pohl (*Játropha Mánihot*, Linn., in part. *Jánipha Mánihot*, HBK.). Bitter Cassava. Mandioca. Manioc. Tapioca Plant. Sweet Potato Tree, and many other names in different tropical countries. Figs. 2322, 2323. An herbaceous shrub

3–9 ft., or small tree in the tropics: roots fleshy, in a basal cluster: lvs. somewhat pubescent, deeply 3–7-parted; lobes 3–8 in. long, lanceolate, acuminate; stipules small, entire: fls. paniculate; calyx less than ½in. long, pubescent inside: caps. wing-angled. Brazil. B.M. 3071.—Cult. in many varieties and naturalized in various tropical lands.

dúlcis, Pax (*Játropha dúlcis,* Gmel.). Shrub, 3–12 ft. high: roots similar to the preceding species but generally smaller: lvs. deeply 3–13-parted; lobes lanceolate to obovate; stipules narrow, pointed, subentire: fls. paniculate; calyx ½–¾in. long, pubescent inside: caps. not wing-angled. Var. **Âipi,** Pax (*M. Âipi,* Pohl. *M. palmàta* var. *Âipi,* Muell. Arg.). Sweet Cassava. Aipi. Younger parts pubescent: lvs. 3–7-parted: lobes obovate to elliptical-lanceolate. Wild in Brazil and cult. there and elsewhere in the tropics. Var. **multífida,** Pax (*M. palmàta* var. *multífida,* Muell. Arg.). Lvs. long-petioled, 7–13-parted, mostly glabrous; lobes spatulate-lanceolate to lanceolate. S. Brazil. H.I. 530.



2323. Manihot utilissima, the roots of which produce tapioca.

cc. *Lf.-lobes sinuate or pandurate or shallowly lobed near the apex, acuminate.*

carthaginénsis, Muell. Arg. (*M. Jánipha,* Pohl. *Játropha carthaginénsis,* Jacq.). Yuquilla. Tree: lvs. 5–7-lobed; lobes lyrate-sinuate; stipules entire: fls. racemose; calyx glabrous, about ½in. long: caps. not wing-angled. S. Texas to Venezuela in sandy soil.

dichótoma, Ule. Tree: lvs. deeply 3–5-parted; lobes broad, entire to sinuate or pandurate; stipules denticulate: fls. in short racemes; calyx ¾in. long, pubescent inside: caps. wing-angled. S. Brazil. H.I. 2876, 2877.

bb. *Lvs. peltate.*

Glaziòvii, Muell. Arg. Ceara Rubber Tree. Manisoba. Tree, up to 40 ft. high: lvs. deeply 3–5-lobed; lobes 3–4 in. long, entire, ovate-oblong to elliptical, short-acuminate; stipules denticulate: fls. paniculate; calyx glabrous, about ½in. long: caps. not wing-angled. S. Brazil and cult. and naturalized in many tropical countries. Jour. Bot. 18:321.

M. diversifòlia, Muell. Arg.=Jatropha integerrima, Jacq.

MANURE (from old French *manœvrer,* to cultivate by hand; connected with Latin for *hand* and *work*). In the broadest sense, manure is any substance applied to the soil for the purpose of increasing productivity. The excrements of animals, mixed or unmixed with straw or other absorbents, are usually spoken of as barn-manures. Commercial manures or "fertilizers" are usually concentrated forms of nitrogen, potash and phosphoric acid, mixed or unmixed (see *Fertilizers*); green manures are living plants plowed under to furnish humus and increase productivity; amendments are substances, such as lime, which may increase the growth and healthfulness of plants by improving the physical condition and modifying the chemical reactions of the soil. In general farming, barn-manures are usually applied in the raw or unrotted state; in horticulture, rotted or partially rotted. Horse-manure is used for hotbeds, while cow-manure, mixed with soil, is best for forming a moist rich potting earth. Dung, the solid voidings of animals, after weathering for a time, is also a valuable addition to potting earth. Florists often keep a number of dairy cattle that an abundant supply of bovine manure, which is so valuable in floriculture, may be at hand. Commercial manures are used in small quantities, either direct or in solution. Nitrogen stimulates the vegetative system and tends to produce rapid growth and dark foliage. Phosphoric acid, among other effects, has that of producing well-developed plump seeds and fruits; potash may augment these effects, as well as increase and intensify the color of the bloom.

Barn-manures are more highly prized than formerly. Waste of their valuable constituents is now largely avoided either by applying them to the land day by day, as they are produced, or by more rational methods of caring for them until they are partly rotted or opportunity is afforded for most suitable application to the land. Covered yards or pits are now sometimes used for temporarily storing manures, where they can have water added if too dry and if likely to "firefang;" or absorbents, such as straw, dry muck, gypsum and the like, may be used if they are too watery. When bedding is abundant, the animals may take their exercise in the covered yard, as they will solidify the manure by tramping it, thereby diminishing loss by too rapid fermentation. Both salt and gypsum conserve plant-food in manures when spread over the mass from time to time in small quantities. The quantity and value of manure made by domestic animals is not realized by those who allow it to be scattered over large open barnyards or allow it to remain for considerable periods under the eaves of the barn. Extended experiments at the Cornell Experiment Station showed that the following amounts of excrements were produced daily for each 1,000 pounds of live weight of animal:

	Pounds
Sheep	34.1
Calves	67.8
Pigs	83.6
Cows	74.1
Horses	48.8
Fowls	39.8

Animals fed on a highly nitrogenous or narrow ration (as 1:4), as were the pigs in the above investigations, consume large quantities of water and produce a large amount of manure, the weight of which often exceeds the amount of food consumed; while those fed on a carbonaceous or wide ration (as 1:9) consume comparatively little water and produce less weight of manure.

Some conditions affecting the production of manure and its value may be stated as follows: If the plant-food value of manure is computed at the price that is paid for the same constituents in fertilizers, it is found that the value of manure produced by animals is equal to 30 to 50 per cent of the cost of their food. Young animals produce poorer manure than mature ones. The excrements of animals which give a product, as milk or young, are poorer than those from non-productive animals. The more abundant the ration the less complete the digestion and the greater the value of the manure produced. Concentrated and nitrogenous foods result in richer and more valuable excrements than unconcentrated or carbonaceous foods. Liberal salting and excessively succulent foods diminish the value a ton of manures. The amount and kind of bedding affect not only the quantity but the value a ton. Animals kept in cold quarters drink little water, digest their food closely and produce a manure relatively small in amount and poor in quality.

Rich manures are relatively more valuable to the unit of contained fertility than poor ones, because their fertilizing constituents are more quickly available than are those of poor ones. Plants receive greater benefit from extra nourishment in the early stages of their growth than when they approach maturity. Coarse low-grade manures should be weathered or rotted to improve their availability, even though some loss may occur. A unit of plant-food in high-grade fertilizers or well-preserved rotted manures is worth more than in low grades. The valuable constituents in farm-manures are not so quickly available as they are in high-grade fertilizers, but they have an additional value, since they furnish humus, lighten the soil, inoculate it with nitrifying organisms and increase its power to hold moisture, while assisting in liberating the mineral constituents of the soil. The value of manure as set down below is determined by investigations during the winter months, and the nitrogen, phosphoric acid and potash are computed at 15, 6 and 4½ cents a pound, respectively. The indirect beneficial effects of manure are considered an equal offset for the slightly less availability of their plant-food constituents as compared with fertilizers:

Kind of manure.	Value a ton.
Sheep	$3 30
Calves	2 17
Pigs	3 29
Cows	2 02
Horses	2 21

Limited amounts of bedding were used in the tests from which the foregoing figures were made.

Kind of animal.	Value a year.
Fowls (1,000 pounds of)	$51 10
Sheep " "	26 09
Calves " "	24 45
Pigs " "	60 88
Cows " "	29 27
Horses " "	27 74

Usually these animals are kept in the stables but half of the year, and inevitably some loss will occur; therefore it will be safe to estimate the recovered value a year at one-third to one-fourth of the above.

Heretofore the waste of the valuable constituents of manures in the United States has been very great. Until recently, large open barnyards have been the rule. In the northern and central parts of the United States the rainfall exceeds 30 inches per annum. Many barnyards contain from ¼ to ½ acre. One inch of rainfall equals 113 tons of water an acre. If this be multiplied by thirty, a fairly accurate estimate is secured of the water which largely passes through or over the manure and carries off its most soluble and hence most valuable constituents. The loss of value in manures exposed at Ithaca, New York, in loose heaps of two to ten tons, during six months, was as follows:

	Per cent
1889. Horse-manure	42
1890. Horse-manure	62
1890. Cow-manure	30
1889. Mixed, compacted	9

Even in horticulture, where a more liberal use of manure than in general farming is admissible, too much reliance is often placed on manures and too little on tillage. Manures may furnish plant-food, improve the physical condition of the soil, conserve and increase heat and moisture. Ten to twenty times as much food as the plants can utilize is frequently applied at one dressing, which is poor economy, since manures give best results when applied in moderate quantities, in a well-rotted condition and in close contact with the seed. Growth and development are more largely determined by the amount of moisture than by the amount of plant-food. Five tons of preserved barn-manure contain of nitrogen, phosphoric acid and potash, sixty, thirty and forty-five pounds, respectively. Twenty-five bushels of wheat, with straw, contain forty-five pounds of nitrogen, eighteen pounds of phosphoric acid, and twenty-seven pounds of potash. Most soils contain large amounts of unavailable or difficultly available plant-food. Manures should be used largely to feed plants between the time the nutrients in the seed have been exhausted and that when the plants have secured a firm hold on the soil by manifold rootlets. Except when otherwise most suitable and convenient, fresh manures should be spread thinly in the autumn or early winter on the surface where plants are growing, thus imitating nature's methods of maintaining and increasing productivity.

It is usually found to be both difficult and expensive to maintain productivity by means of barn-manures supplemented with light applications of fertilizers. In this case, unless plant-food can be secured from outside sources easily, recourse should be had to green-manuring. In some cases this is the cheapest and the best method of rejuvenating old, weedy, tired lands. By raising and plowing under two crops—one at least a legume—in one season many weeds may be destroyed, quantities of humus and nitrogen added, and inert plant-food transformed into readily available forms. At the same time the soil is improved physically and its power to pass the free water of precipitation through its subsoil is augmented while the tendency to puddling is diminished. Added humus and tillage combined hasten nitrification and the liberation of inert mineral plant-food while imparting to the land a greater capacity to hold moisture by capillary action. See *Fertility*.

I. P. Roberts.

MAPÀNIA (an aboriginal name). *Cyperàceæ.* Grass-like or sedge-like plants, sometimes grown under cover for the foliage effects.

Stem very short, bearing long and often striking lvs.: scapes mostly leafless, bearing congested infl.: spikelet of 6 (sometimes 5) glumes: fr. a bony nut either dry or succulent.—There are perhaps 50 species in the tropics of both hemispheres, comprising strong often tall-lvd. perennial herbs. Two species, apparently good pot subjects, have been listed in recent years. *M. pandanæfòlia*, Hort., is represented as dracena-like, caulescent, 3–4 ft. high, with long narrow graceful stiffish lvs. 24 in. long by 1 in. wide. G.C. III. 21:349. Gt. 46, p. 523. It is perhaps *M. Pandanophýllum*, Schum. & Hollr., which is *M. hypolytroìdes*, Benth., of

Malay peninsula to Austral. (*Pandanophýllum hypolytroìdes*, F. Muell. *Hypólytrum Pandanophýllum*, F. Muell.). This much-named plant is separated by C. B. Clarke as *Thoracostàchyum hypolytroìdes*, Clarke, a genus differing from Mapania in its corymbose rather than congested spikes. The lvs. are described as 4 ft. long and 1–2 in. broad, with scabrous edges: lowermost involucral bracts 1–2 ft. long and ½–1 in. broad, tapering to long points: spikelets very numerous, whitish.

Apparently the only other species recently offered regularly is *M. hùmilis*, Naves & Vill. (*M. lùcida*, N.E. Br.). Rhizome short and woody, terminating in a short st. or crown bearing a top of densely equitant lvs., which are 2–3 ft. long, 3-nerved, sharp on margins and keel: scapes from the lower axils, the mature infl. ovoid, the bracts shorter than the head. India.

L. H. B.

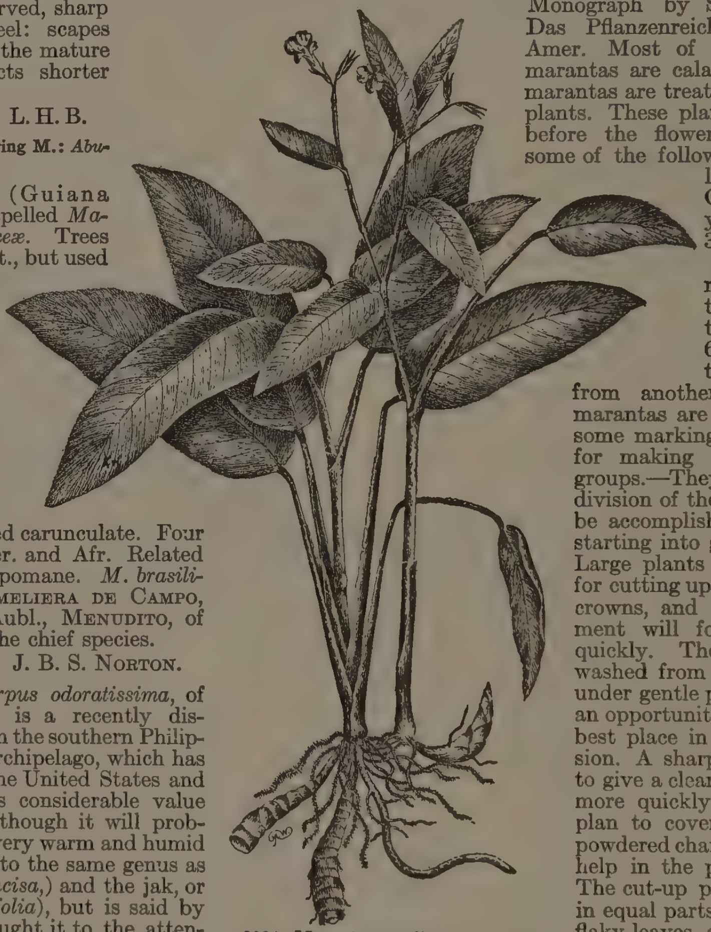
MAPLE: *Acer.* **Flowering M.:** *Abutilon.*

MAPROÙNEA (Guiana name). Sometimes spelled *Maprounia. Euphorbiàceæ.* Trees and shrubs, not in cult., but used for medicine and the like, in their native land. Glabrous: juice milky: lvs. entire, pinnately veined: infl. terminal; fls. apetalous, monœcious; staminate calyx 2–3-lobed, lobes imbricate; stamens 1–3, filaments connate; ovary 3-celled; 1 ovule in each cell: seed carunculate. Four species in Trop. Amer. and Afr. Related to Stillingia and Hippomane. *M. brasiliénsis*, St. Hil., Marmeliera de Campo, and *M. guyanénsis*, Aubl., Menudito, of Trop. S. Amer., are the chief species.

J. B. S. Norton.

MARANG, *Artocarpus odoratissima*, of the family *Moraceæ*, is a recently discovered fruit-tree from the southern Philippines and the Sulu Archipelago, which has been introduced to the United States and is thought to possess considerable value for tropical regions, though it will probably succeed only in very warm and humid climates. It belongs to the same genus as the bread-fruit (*A. incisa*,) and the jak, or jack-fruit (*A. integrifolia*), but is said by Wester, who first brought it to the attention of horticulturists, to produce a fruit superior in quality to the Philippine forms of either of these. The tree is medium-sized, and similar in habit to the bread-fruit, with large, dark green, entire or trilobate leaves 18 to 24 inches long by 10 to 12 inches broad. Wester describes the fruit as "large, about 6 inches long and 5 inches in equatorial diameter, roundish oblong, regular, thickly studded on the outside with soft greenish yellow spines ⅓ inch in length; rind thick and fleshy; flesh white, sweet, rich, juicy, aromatic and of good flavor, separated into segments (of about the size of a grape) clinging to the core, each segment containing a seed; the seeds many, whitish, ⅓ by ⅗ of an inch, smooth, separating readily from the flesh. When the fruit is ripe, by passing a knife around and through the rind, with a little care the halves may be separated from the flesh, leaving this like a bunch of white grapes." It is said to ripen during August in the Philippines. For species related to *A. odoratissima*, Blanco, see the article *Artocarpus*, pages 401,402, Vol. I.

F. W. Popenoe.

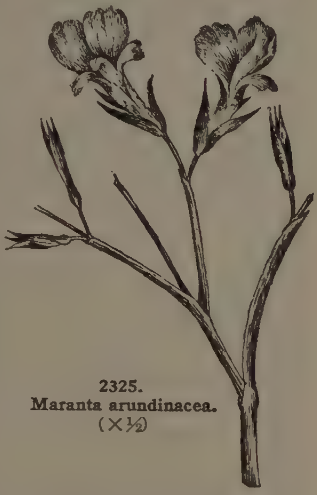


2324. Maranta arundinacea. (×⅛)

MARÁNTA (B. Maranta, Venetian Physician and botanist, died 1754). *Marantàceæ.* Greenhouse pot plants, grown mostly for the foliage.

Perennial herbs, tall or low, erect or prostrate, the flowering part more or less branched: lvs. petiolate, radical and cauline: fls. racemose or paniculate; sepals 3, equal, lanceolate or lance-oblong; corolla more or less tubular, usually enlarged or gibbous at base, the 3 lobes subequal and somewhat hooded at the apex; 2 exterior staminodia petal-like, usually obovate, showy; ovary 1-celled by abortion.—Species 23 in the Monograph by Schumann (hft. 11, Das Pflanzenreich, 1902), in Trop. Amer. Most of the plants cult. as marantas are calatheas; and the true marantas are treated the same as those plants. These plants are often named before the flowers are known, and some of the following plants may belong to the genus Calathea. The genus yields arrow-root (p. 397).

The culture of maranta is that of calathea, which is detailed in Vol. II, p. 619; but the directions may be reviewed from another experience. The marantas are grown for the handsome markings of the leaves, and for making complete foliage groups.—They are increased by division of the crowns, which may be accomplished just as they are starting into growth in the spring. Large plants are the best to use for cutting up, as they have strong crowns, and under proper treatment will form a plant more quickly. The loam should be washed from the root with a hose under gentle pressure. This gives an opportunity to see where is the best place in the crown for division. A sharp knife must be used to give a clean cut, which will heal more quickly. It is also a good plan to cover the cut part with powdered charcoal, which is a great help in the prevention of decay. The cut-up pieces may be potted in equal parts of the fiber of loam, flaky leaves, and sharp sand; add also a small part of broken charcoal. The pot should be big enough to admit the roots without breaking or crushing them and they must be supplied with good drainage.—Marantas like abundance of moisture at their roots. The water, however, must pass freely through them, otherwise they soon get into a sour stagnant condition. Divided plants should be kept in a temperature of not less than 65° and the house must be kept in a humid condition by light syringing, and dampening between the pots on the bench, and in the paths. Change the air in the house by ventilating, as soon as the thermometer reaches 75°. Shade the plants from early spring until late autumn, as the bright sunshine will soon destroy the foliage and make the plants unsightly. Repotting is not necessary until the following spring.—In December, January and February, marantas may be allowed to get quite dry at the roots before watering. By this treatment they seem to start into a more vigorous growth, when they get a shift into a larger pot early in March. Established plants may be potted in a rather rough soil consisting of the fiber of loam two parts, flaky leaves one part, a small part of good sharp sand and another part of dried cow-manure. Add a sixth part of broken-up charcoal to the whole compost. Pot moderately firm, by pressure of the hands, and raise the crown a little in the center. In summer, admit plenty of air during the day, and leave a crack of top air on all night. This insures a strong healthy growth, and the plants may be used for decorative work, without suffering any damage. Tropical plants have been brought into disrepute by what may be termed the sweat-box treatment, which is entirely unnecessary. A soft flabby growth is the result of such usage. When in active growth, marantas may be watered with manure-water. Cow-manure water and soft-coal soot agree well with them. An ordinary handful to a 2½-gallon watering-pot will be found to be sufficient. Apply after watering twice with clean water. If marantas are well syringed under the leaves, insect pests are not troublesome. If they obtain a foothold, sponge the leaves with some reliable insecticide. (George F. Stewart.)



2325. Maranta arundinacea. (×½)

A. *Lvs. green, pubescent beneath*

arundinàcea, Linn. Figs. 2324, 2325. Branched, 2–6 ft. high, tuberous: lvs. ovate-oblong to ovate-lanceolate and pointed, at the base rounded or truncate: fls. white in an open cluster, the upper lip roundish; staminodia surpassing corolla. Trop. Amer.; naturalized in S. Fla. B.M. 2307.—One of the sources of arrow-root, the plant being often called Bermuda arrow-root. The starch is obtained from the roots. It thrives along the Gulf coast, although little cult. There is a form with lvs. variegated green and yellow.

AA. *Lvs. green, marked with strong parallel light-colored bars extending from midrib toward margin or with a whitish central stripe.*

spléndida, Lem. Glabrous: lvs. 2 ft. or less long, the blade large, oblong-lanceolate, with base subcordate or somewhat cuneate, short-acute at apex, above shining dark green and marked with pale green transverse bars, beneath violet-red. Brazil. I.H. 13:467, 468.—By some regarded as Calathea (*C. splendida*, Regel), but its position is doubtful. Resembles *Calathea Veitchiana*, but more robust.

AAA. *Lvs. blotched or banded with dark colors (sometimes contrasted with silvery colors).*

leuconeùra, Morr. Dwarf, the st. and lvs. about 1 ft. high, not tuberculate at base: lvs. oblong or broadly elliptic, usually obtuse or very short-acuminate, grayish green, white striped or banded along the veins, and marked with darker green, glaucous or purple beneath; outer staminode white, obovate and emarginate. Native in Brazil.

Var. **Massangeàna,** Schum. (*M. Massangeàna*, Morr. *M. bícolor* var. *Massangeàna*, Hort.). Lvs. smaller, beautiful purple beneath: fls. somewhat smaller, the sepals about ⅙in. long: staminode deep violet, somewhat 3-lobed.

Var. **Kerchoveàna,** Morr. (*M. Kerchoveàna*, Hort.). Lvs. larger, glaucous or red-spotted beneath: fls. larger; staminode entire.

bícolor, Ker (*Calathèa bícolor*, Steud.). A foot or so high, the st. tuberculate at base: lvs. linear-oblong or elliptic, rounded or subcordate at the base, more or less wavy on the margin, abruptly short-pointed, light purple below, pale glaucous green above, with a relatively light-colored central band and very dark green or brown-green blotches midway between the rib and the margins. Brazil. B.R. 786. L.B.C. 10:921.

See *Stromanthe* for *M. sanguinea, M. Porteana.*

See *Monotagma* for *M. smaragdina.*

See *Ctenanthe* for *M. Kummeriana, M. Luschnathiana, M. Oppenheimiana, M. setosa.*

See *Ischnosiphon* for *M. bambusacea* (M. bambusæfolia?), *M. major.*

See *Calathea* (some of them in the supplementary list) for *M. Alberti, M. albo-lineata, M. argyrea, M. Bachemiana, M. Baraquinii, M. Chantrieri, M. chimboracensis, M. eximia, M. fasciata, M. fascinator, M. Gouletii, M. hieroglyphica, M. illustris, M. insignis, M. Lageriana, M. Legrelliana, M. leopardina, M. Lietzii, M. Lindenii, M. Makoyana, M. medio-picta, M. micans, M. musaica, M. nitens, M. ornata, M. picta, M. princeps, M. pulchella, M. regalis, M. roseo-lineata, M. rosea-picta, M. Sanderiana, M. tigrina, M. tubispatha, M. Vandenheckei, M. Veitchiana, M. virginalis, M. vittata, M. Wagneri, M. Wallisii (Wallichii?), M. Warscewiczii, M. Wiotii, M. zebrina.*

Other marantas with Latinized trade names are in recent lists, but not all of them are identifiable botanically. *M. amábilis.*—*M. argéntea*, "large oblong silvery gray lvs., marked with narrow lines of green."—*M. bélla*, Bull (Calathea bella, Regel, which is probably the correct name). Stemless: lvs. about 6 in. long, oblong, acutish, whitish green above, pale purple beneath.—*M. Clósonii.* Lvs. dark green, variegated with pale yellow. Brazil.—*M. Goveniàna.*—*M. iconífera* (a form of Calathea Makoyana?), has lvs. about 6 in. long, obliquely oval, yellowish green, with oblong, deep green spots or bars. Brazil.—*M. Liebrechtsiàna.* Lvs. large, oval, green, decorative. Congo. Clinogyne (?).—*M. Lùbersii.* Foliage reticulated with yellow.—*L. Lujaiàna.* Lvs. handsome, long-stalked, purple beneath. Halopegia (?).—*M. mosélla.*—*M. orbifòlia*, "strong grower, olive-green with broad silvery bands."—*M. Sagoriàna.* Dwarf: lvs. oblong, pale green, with oblong-oblique, deep green bars on each side of the midrib. S. Amer.—*M. Spitzeriàna.*—*M. triúmphans.*—*M. undulàta*, Lind. & André (properly Calathea undulata, Regel). Six to 8 in. high, compact: lvs. ovate-oblong, the blade about 4 in. long, subcordate and unequal at base, very short-pointed, the surface undulate, beneath purplish, above deep shining green, with a whitish feathery stripe through the center. Peru. I.H. 19:98.

L. H. B.

MARÁTTIA (name from J. F. Maratti, an Italian botanist of the 17th century). *Marattiàceæ.* A genus of large, coarse-lvd. stipulate tropical ferns with the large fleshy sporangia borne in boat-shaped groups on the under surface of the lf. The species are strong-growing and ornamental, some of them reaching considerable size. Besides the following, there are several American species which deserve cult. For cult. requirements, see Angiopteris, p. 1214.

2326. Marattia fraxinea. (×⅛)

fraxínea, Smith (*M. élegans*, Endl.) Fig. 2326. St. erect, tuberous: lvs. bipinnate, 6–15 ft. long, the stalks often 1 in. or more thick; pinnules 4–6 in. long, ½–1½ in. wide, of a leathery texture and naked surfaces: receptacles submarginal. W. Afr. to Malaysia and New Zeal.

M. Stanleyàna, Hort., has not been sufficiently described to be identifiable.

L. M. UNDERWOOD.

MARCGRÀVIA (Georg Marcgraaf, born 1610, a very early writer on Brazilian natural history). Sometimes spelled *Marcgraavia* and *Marcgrafia*. *Marcgraviàceæ;* by some authorities included in *Ternstrœmiàceæ.* Climbing epiphytic shrubs, one of which is offered abroad as a warmhouse plant: lvs. entire, short-stalked, coriaceous: fls. in terminal umbels or racemes, the corolla cap-like and falling as a single piece; sepals 6, 2 smaller; stamens mostly many (sometimes as few as 12): fr. globose to ovoid, more or less fleshy, with numerous seeds. Species probably 40, many of them recently described in Trop. Amer. **M. umbellàta,** Linn., W. Indies and S. Amer., is a polymorphous plant, the sterile shoots creeping and rooting: lvs. on the rooting shoots distichous, nearly sessile, cordate and emarginate, on the other shoots oblong to linear: fls. greenish, umbellate: fr. with red pulp: clings to trees by roots.

MARCHÁNTIA (Marchant, French botanist). *Marchantiàceæ.* A common liverwort (one of the Bryophyta; see p. 6, Vol. I) spreading its lf.-like forking thallus on moist earth. *M. polymórpha,* Linn., has been offered by dealers in native plants, the sods of it being sold for colonizing in rock-gardens. It frequently grows on damp sills and walls in greenhouses. The flat thallus is often 4–5 in. long and 1 in. or more wide, from which rise peduncles 1 in. high, bearing the antheridial disk or shield and the star-like carpocephalum on similar stalks 1–3 in. high.

MARGUERITE, a popular name for certain daisy-like plants, the word related in origin to the Greek for *pearl,* as also *margaritaceous,* "pearly;" from the same root is derived the personal name Margaret and others. In florist's usage, the marguerites are species of Chrysanthemum. Blue marguerite is *Felicia amelloides,* and Reine marguerite of the French is the China aster. There are two types of marguerites, the common one, or Paris daisy, with coarse green foliage, and the glaucous marguerites, with finer cut glaucous foliage. The former, *Chrysanthemum frutescens,* is better for cut-flowers. The latter, *C. anethifolium,* is probably better for large specimens.

Marguerites are standard useful plants with florists and in the conservatories of amateurs, being of easy culture and remarkably free from enemies. They are cultivated for two distinct purposes,—for cut-flowers and for specimen plants, young plants being used for the former purpose, and older ones for the latter. For cut-flowers, the cuttings are rooted in spring, and the florists usually keep the plants in pots all summer outdoors, though this is not necessary for amateurs, and flowers are produced during the following winter. It is sometimes said that marguerites do not lift well in the fall after being planted out all summer in the garden, and that unrestricted root-room makes the plants too large for the best production of cut-flowers. The principles underlying the matter are as follows: In turning plants out of pots into the open ground in spring, a plant that has filled its pot well with roots tends to make a much more compact root-system in the garden than the plant that had but few roots in its pot, and the former plant is easily lifted in the fall and with less damage to the roots. As a matter of fact, marguerites do not belong to the class of plants that are difficult to lift in the fall, and it is only a question of starting the cuttings early enough in spring to get the plant moderately pot-bound before it is planted out into the open ground. Specimen plants are most attractive in the second winter following the spring in which cuttings were struck. After that they are likely to become too large and straggling. While in the garden, the flowers should not be allowed to form, if the main object is high-grade cut-flowers in quantity for the winter. Old plants that are unfit for further use in the conservatory may be turned out in summer and will furnish scattering bloom all summer, though the flowers are likely to be rather small. If there were sufficient demand, it could be easily managed to have flowers in every month of the year. It is a great pity to cut marguerites without any foliage. The rule is that all flowers look best with some foliage, especially their own. With a little forethought, just as many flowers can be secured, and they will look much prettier and last longer. There are very few conservatories without some marguerites. An excellent plan is to have a number of plants in 6-inch pots from cuttings struck the previous spring. A plant looks bad at first when the flowers have been removed on sprays a foot long, but in a short time they are ready for cutting again. With a little management, a succession of flowers can be maintained without making all the plants thin or unsightly. Such sprays will last a week or two in water, and the opening of the larger buds is an additional feature of beauty which is lost if flowers are cut with short stems and without foliage. (Robert Shore.)

MARGYRICÁRPUS (Greek, *pearly fruit;* referring to the white berries). *Rosàceæ.* South American sub-shrubs, of which *M. setosus* is a heath-like plant cult. in rockeries for its numerous small white berries, which are seen to best advantage against dark background. The nearest genus of garden value is Acæna, which has fls. on heads or spikes, while those of Margyricarpus are solitary and axillary. Branching shrubs with inconspicuous fls. which are sessile and have no petals: lvs. alternate, crowded, overlapping: calyx-tube persistent; lobes 4–5; ovary 1, in the calyx-tube, with very short style; ovule solitary, hanging from the top of the cell: fr. a coriaceous achene.—Species a half-dozen and more, in temperate parts of mountains and south to Patagonia.

setòsus, Ruiz. & Pav. Pearl Fruit. Low-growing little evergreen (about 1 ft.): lvs. odd-pinnate with subulate more or less reflexed lfts.: fls. very small, green, sessile in the axils: fr. white, showy and persisting for some time, small. Peru, Chile.—Hardy in England. Intro. in S. Calif.

M. hýbridus is offered abroad as a "pretty evergreen alpine shrub thickly studded with rose-colored berries." L. H. B.

MÀRICA (meaning doubtful; perhaps from the verb *to flag*). *Iridàceæ.* Tropical plants allied to Iris, but with shorter-lived flowers and convolute inner segments.

Rootstock a short rhizome: lvs. sword-shaped, 2-ranked: fls. blue, yellow or white, very fugitive, in clusters on a flat and lf.-like peduncle, 2–4 in. across, the outer segms. large, white or blue, the inner ones smaller, fiddle-shaped, with beautiful coloring; stamens short and erect, the filaments distinct: caps. oblong, 3-valved, many-seeded.—About a dozen perennial herbs, in Trop. Amer. and 1 in Guinea (Afr.) They are planted in the fall, and are hardy with winter covering in the warmer parts. The genus is nearest to Cypella, but the style-crests are petal-like, while in Cypella they are spur-like or flattened; in Cypella the lvs. are plicate rather than distichous and the rootstock is bulbous.

A. *Outer segms. white, or marked at the base with brown and yellow.*

grácilis, Herb. Lvs. 6–8 in a tuft, sword-shaped, 1–1½ ft. long, ½–1 in. broad: peduncle long and flat, bearing fls. at some distance from the end and sometimes taking root from the top; fls. 2 in. across; outer segms. obovate, white, with cross-marks at base of yellow and brown; inner segms. small, reflexed, blue. Mex. to Brazil. B.M. 3713. Gn. 63, p. 37.

Northiàna, Ker. Lvs. about 8 in a tuft, sword-shaped, bright green, about 2 ft. long and 1½–2 in. broad: peduncle 3 ft. long, as broad as the lvs., with about 2 clusters near the apex; fls. 3–4 in. across; outer segms. pure white and obovate, variegated on the claw;

inner segms. with violet tip and variegated claw. B.M. 654. I.H. 42:40 (var. *splendens*). Gt. 61, p. 91. G.L. 26:137. Gn. 65, p. 289. F.S.R. 3:52.—Handsome; a good subject for a basket.

AA. *Outer segms. blue.*

cærùlea, Ker. Lvs. 6–8, sword-shaped, 1–1½ in. broad and 2–3 ft. long: peduncle long, as broad as the lvs., bearing 2–4 fl.-clusters: spathes 2–3 in. long, the outer valves green and lanceolate: fls. 3–4 in. across, bright blue or lilac, the outer segms. 1–1½ in. across and variegated at base with transverse bars of yellow, white or brown, the inner segms. with recurved blue point. Brazil. The African *M. Sàbinii*, Lindl., Baker considers to be probably only a form of *M. cærulea*, and intro. into Upper and Lower Guinea. B.M. 5612 (as *Cypella cærulea*). B.R. 713. Gn. 25, p. 313; 33:56. J.H. III. 49:17.

Hélenæ, Worsley. Related to *M. cærulea:* fls. nearly 5 in. across, blue and white, on long lf.-like scapes: drooping segms. or "falls" much longer than in *M. cærulea*, somewhat narrower, indigo-blue, the reflexed apices measuring 2½ in. long; standards much more distinctly vittate, deep velvet-blue in 2 marginal stripes with a keel of white of equal width between them; plant also hardier, withstanding some frost. Brazil.

L. H. B.

MARIGOLD. The original kind is the pot marigold, the dried flowers of which are used to season soups. It is also cultivated for ornament. See *Calendula officinalis*. The **French Marigold** is *Tagetes patula;* the **African,** *T. erecta*. The African marigolds are mostly pure lemon- or orange-colored; the French ones have these colors and brown also, and are often striped. For **Cape M.** see *Dimorphotheca*. For **Fig M.** see *Mesembryanthemum*. **Marsh M.** is *Caltha palustris*.

MARIPOSA LILY: *Calochortus*.

MARIPOSA TULIP: *Calochortus*.

MARJORAM, SWEET: *Origanum*.

MARKET-GARDENING is the growing of vegetables for commercial purposes by the employment of the most skilful methods. It is one of the most intensive types of vegetable-gardening. Land values, where market-gardening is practised, are usually high, and it is necessary to secure large returns to the acre in order to realize a profit on the investment. The crops which receive most consideration by market-gardeners are beets, onions, celery, lettuce, radish, carrot, parsley, endive, and other vegetables which are usually planted close together and cultivated with hand wheel-hoes.

Truck-gardening, or truck-farming, is the growing of vegetables for market by the employment of extensive methods. Less intensive methods are followed in truck-gardening than in market-gardening. Land values are lower and it is unnecessary to obtain large cash returns to the acre in order to make the business profitable. The trucker relies mainly on such crops as the cabbage, tomato, sweet corn, asparagus, pea, bean, cucumber, watermelon, muskmelon, sweet potato, and other crops which require liberal spacing and which are usually cultivated by horse-power.

Market-gardeners are usually located near the towns or cities in which the vegetables are sold, although there are exceptions; truckers, as a rule, are remote from market. The best examples, and the most extensive areas, of market-gardeners are near the large cities —New York, Philadelphia, Boston, Chicago, Baltimore, Washington, San Francisco, Toronto, and Quebec.

Vegetable-forcing is the growing of vegetables under glass, or canvas, or in specially constructed houses which are heated by artificial means.

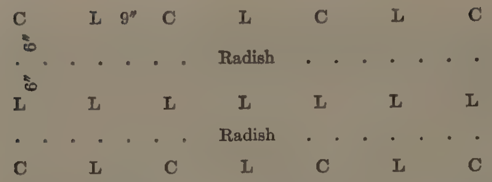
In choosing a location for market-gardening, too much attention cannot be given to the market demands of the locality and how fully they are met by growers already operating in the community. There should be the best of roads and of transportation facilities to the markets to be supplied. Liberal supplies of stable-manure should be easily obtainable at reasonable prices. A sandy soil is a distinct advantage; it is easily cultivated, and with good management produces vegetables of the highest quality early in the season. On account of the uncertainty of an ample supply of rain throughout the season, crop-production will be made more certain and profitable by irrigation, and there should be no shortage in the water-supply. An abundance of pure water will also be needed in preparing the vegetables for market. The supply of labor should also be taken into account in the choice of a location.

High fertility of the soil is a prime factor in the successful operation of a market-garden. The land must be in the proper physical condition if crop-yields are to be satisfactory. Available plant-food must be present in adequate quantity throughout the growing season. Stable-manures are universally applied in large amounts by market-gardeners. It is not uncommon to apply forty or more tons to the acre. Such large applications annually increase the percentage of organic matter in the soil, thus providing the best physical, chemical, and bacteriological conditions for plant growth. While many gardeners rely wholly upon stable-manures as a source of plant-food, others find it profitable to employ commercial fertilizers, varying in amount from a few hundred pounds to two tons to the acre. Complete fertilizers are generally employed, and they usually contain about 4 per cent of nitrogen and from 7 to 10 per cent of each of the mineral elements—potash and phosphoric acid. Lime is often used to make heavy soils more friable, to prevent the ravages of club-root, and to maintain an alkaline condition in the soil, which is important from the standpoint of avoiding mal-nutrition diseases.

Market-gardeners usually do not attempt to cultivate large tracts of land. Occasionally, a man will handle 50 to 75 acres, but most of the growers have less than 25 acres and thousands of them less than 10 acres. By the employment of the most intensive methods, a living may be made on 2 or 3 acres, although most gardeners will do better on a larger area. Small areas require the use of more glass, in the way of hotbeds and coldframes or perhaps greenhouses.

Inasmuch as a livelihood must be made from a small area of land, it is necessary to keep every foot or inch of the place occupied with a crop throughout the growing season. The first crops are started early in the spring, just as soon as the ground is dry enough to work, and they follow each other in close succession until late in the fall. By skilful management, it is possible to grow four or five crops on the same land in one season. Companion-cropping is common among market-gardeners, and, in order to make the soil do its maximum duty, one crop is often planted before the preceding one is harvested. For example, immediately after the last wheel-hoe cultivation of beets, planted in rows a foot apart, rows of lettuce may be drilled midway between the beets. When the lettuce is about ready to harvest, carrots may be drilled between the rows, and these may be followed by some other small crop, and so on until late autumn. When companion-cropping is practised, it is important to have straight rows, so that there will be uniformity in the spacing between the rows. This is essential if wheel-hoes are to be used in the most effective manner, and straight rows also make a more attractive garden.

The greatest variety of companion-cropping plans may be practised. The following plan, with C representing cabbage, L, lettuce, and R, radish, shows the possibilities of this system:



In considering intercropping plans, the gardener should be well informed concerning the requirements of each crop,—its habit of growth, soil-adaptation, space-requirement, susceptibility to disease and insect depredations, time of maturing, and the like.

The outlook for market-gardening in America was never more encouraging than at the present time. Great advances in prices need not be expected, but the rising prices of meats will unquestionably favorably influence the market for vegetables. Our markets are demanding the highest quality of vegetables, and every gardener should attempt to grow the best and to place it on the market in the most attractive condition. Profits in market-gardening depend quite as much upon the grower's ability as a market-man as upon his skill in production.

R. L. WATTS.

MARKETING OF HORTICULTURAL PRODUCE. The growing and disposing of horticultural products have from earliest times been bound together. Within the past decade, the tendency to dissolve the marketing from the production has been developing very perceptibly. This division of labor has doubtless been due to the rapid increase in the amount of detail and skill required to do both producing and marketing successfully.

The business of disposing of horticultural products is now somewhat specialized and follows fairly well-defined lines. These may be described as (1) marketing directly to the consumer; (2) marketing indirectly or through middlemen of the many and various kinds; (3) marketing through coöperative associations.

Marketing directly to the consumer.

By this is meant sending the produce directly from the producing region. This is the simplest, easiest and most satisfactory of all ways. The producer, in this way, receives the best returns for his crop, and the consumer secures the produce for the most reasonable price and without the delays between harvesting and selling which very often cause serious deterioration. Many fruit- and vegetable-growers have worked up a satisfactory business by disposing of their products in this way. This is usually initiated by friends of one or both parties and later supplemented by cards inclosed in the package and by advertisements. It is a fairly common practice for fruit-growers to sell directly to an association of farmers in a grain or dairy region. A personal confidence between the grower and the consumer develops from this method of dealing, and so long as neither side destroys this confidence the customer becomes an advertising agent for the grower.

It was thought that the parcels-post system would stimulate direct selling. It has been practised to some extent, but there seems to be no very immediate likelihood that it will become a large factor for bringing the horticultural producer and consumer together. So many horticultural products are of a highly perishable nature, while many of a less perishable nature are too bulky.

In some cities, marketing directly to the consumer is done through city public markets, with satisfactory results to the producer and the consumer. These marketing centers are usually constructed by the cities, and for a small fee the farmers, gardeners and fruit-growers rent stalls or stands. Rules and regulations for the conduct of the business of selling are usually prescribed by the city government, and they are enforced by the superintendent of markets or other official in charge. The market is opened and closed and selling is active at designated hours. Usually all sales are made for cash and the buyer carries home all produce purchased. This marketing brings closely together, to their mutual benefit, the producer and consumer. As the overhead expenses of marketing are reduced to a minimum, the public markets have been important factors in reducing the cost of living in many communities.

Marketing indirectly or through middlemen.

A large part of the horticultural products are sold by the grower to jobbers, dealers and retail merchants. This is the next step in the evolution from direct selling. Much harsh criticism has been applied to the middleman; however, there can be no doubt but that he has an important place in the disposition and distribution of horticultural products. The marketing and distributing has rapidly become such an intricate, extensive and specialized business of itself that few fruit-growers can afford the time or have the business training or skill required to do this work well.

There undoubtedly always will be a place for the middleman in the distribution of produce so long as many kinds, grades and varieties of products similar in a general way are grown on small farms and sent to distant markets to be sold.

The middleman is, in reality, a distributor. It would be impossible for the men who grow the crop to place or distribute it in markets over the country so that it might be purchased at a reasonable price in many regions, and not permitted to accumulate in too large quantities in some markets while in others there would be a scarcity or nothing. Horticultural products are, in a large number of cases, highly perishable and markets must be provided some time in advance of the ripening of the crop. This requires capital, familiarity with trade in many sections, confidence, good-will, and wide acquaintance with the many outlets.

The general term "middleman" may include buyers, commission men, jobbers, dealers, brokers, auction companies, solicitors, speculators and distributing agencies.

(a) *Buyers and jobbers.*

The term "buyer" in the mind of the truck- or fruit-grower, in most producing sections, is any individual who is located at the shipping-stations and endeavors to buy produce from the grower as it is brought in from the gardens and farms. These buyers may be operating the business for themselves, endeavoring to get together a carload of mixed or similar products to be shipped or consigned to the market. They may be representatives of a jobbing or commission company, working on a salary or commission on the business accomplished. It is their entire purpose to buy the highest grade and best packed products at the lowest price that the grower will take for them. These buyers may buy one or several kinds of produce but usually they want but one kind and one grade. These men make a special business of buying one kind of produce at a time and many of them "follow the crop," i.e., begin in the southern states to buy when the crop is harvested and move north as the later crops are ready for market. This applies especially to strawberries, potatoes, peaches, and tomatoes. They do not have an office or permanent location and may or may not return to the same place season after season.

Carlot purchasers are classified as "jobbers." They usually have a permanent location, an office, scales, and other equipment and return season after season to the same place. This is especially true in some of the important potato-growing sections.

Some jobbers have a warehouse or store in the city and do a general fruit and produce business through the store, or by handling direct shipments from the producing center to the market.

(b) *Broker.*

The term "broker" is commonly applied to that class of middlemen who may buy supplies from shippers, commission men, or at auctions in the quantity and grade they desire and immediately resell it to retailers in small lots. A broker may have a business along a definite line, as citrous fruits or apples, developed in a section of a large city, and keep in close touch with the needs of his customers (usually men doing a small and mixed business and very frequently foreigners not familiar with the English language) and supply them from day to day. Frequently these men do a large business without an office or permanent headquarters or any equipment. They know each morning the needs of their customers for the day; and accordingly, buy the goods in large quantities, which are delivered directly from the purchasing-point to the retail dealer. The difference in the large-lot buying price and the small-lot selling price becomes the broker's profit.

(c) *Commission men.*

The field occupied by "commission men" in the produce trade is well defined and understood. It is an important one, and they are real factors in the distribution of produce of all kinds. The commission man, firm or company, has permanent headquarters in the produce-selling neighborhoods of the city, usually a store and necessary equipment, and rent cold-storage space as their needs require. They advertise and have agents or solicitiors located in the producing regions to induce the growers to ship to them all or only one kind of any produce they may grow, as fruit, vegetables, butter, eggs, and poultry. This is usually sold very shortly after it is received to customers who may be brokers or large consumers, as hotels; but usually they are proprietors of groceries, fruit-stores, or -stands. Such a method makes it necessary for the commission firm to keep in close communication with the two great classes, the growers and the consumers. They are in reality a go-between or connecting link between these two classes. They have, as a class, received for a long time very severe criticism for making false reports upon the condition of produce on its arrival to them and also for making untrue returns to the grower, but these instances are no different from those that probably exist in many other lines of business. There are many honest commission firms that have been very important factors in assisting growers to build up a profitable business. The grower must do his part honestly to give the commission man a chance, and the seller must work for the interest of his shippers. Sincere coöperation is necessary upon both sides. The best results have been obtained in cases where an honest, fair-minded grower has coöperated with an honest commission dealer over a series of years. If the grower packs his produce in a uniform way and gives the dealer the opportunity to develop a class of trade for that particular grade and to know about what he can depend upon receiving, he can secure and hold permanent customers.

The grower may very materially coöperate with the commission man and assist him to secure better prices if he adopts and consistently uses an attractive label on packages of superior produce. Buyers of all classes quickly learn to what extent they can depend upon a labeled or trade-marked package. Thousands of packages of fruits, oranges and lemons especially, are sold entirely upon the reputation behind the label upon the end of the box. A label once adopted and honestly used by a grower should not be changed or altered in any way; if so, any accumulated benefit will be quickly lost. It must be understood that large quantities of produce are sold to persons who cannot read the English language but will remember a picture or design in connection with a grade of produce.

Immediately after the produce is sold, the returns are made to the grower, accompanied with a statement showing the selling price, the commission for making the sale, the transportation, cartage, storage and other shipping expenses deducted.

(d) *Dealers.*

A group of men to be found in the produce trade may be classed as straight buyers or dealers. They are not so numerous as commission men, but in some lines of produce-handling are very important factors. These dealers usually buy produce direct and outright from the growers. It may be immediately sold, but it is frequently stored, and sold to the regular customers of the dealer. This type of marketing produce is often somewhat limited to such staples as apples, potatoes or onions, but may include the shorter-lived commodities as berries, peaches and green vegetables. It is straight direct dealing upon the part of the producer and the dealer. The producer knows exactly how much he will receive for the quantity of produce he has and the dealer knows the price he must charge his customers. It is the business of the dealer to keep well informed upon crop conditions and prospects in all parts of the country for the commodity he is specializing in, or those that may compete with it, and to keep the needs of his customers supplied with a grade of produce their trade demands.

Many growers have enjoyed such business relations with dealers over long periods of years, both parties coöperating and keeping in close touch with each other, resulting in their mutual good.

(e) *Auctions.*

In many of the larger cities, great quantities of produce are sold by auction. Companies may be organized by several men engaged in the general produce trade; by a group of producers; by a group of buyers; or they may be formed by independent companies. The charge for making the sale is a percentage upon the gross receipts and is not often more than 5 per cent, frequently less. These auctions are, in most cases, located in the large distributing centers, but in a few instances they are located at the producing region.

The large quantities of fruits and vegetables imported into the country are nearly all sold through the auctions, as are many of the products from the Pacific coast and other western regions; also from Florida and some other regions where products of one kind are extensively produced. Auction selling is a very rapid way of moving large quantities of produce in a short time. Frequently as many as fifty carloads are sold in a few hours.

Produce may be sent to the auction company by carlot growers, shippers, buyers, dealers, associations, or other receivers. It is purchased by men whose business it is to buy for large stores or chains of stores, brokers, or large consumers.

The auction company controls a warehouse where the produce to be sold is displayed; an auction- or salesroom where the actual selling is done, and offices. A list or manifest of the contents of the carload to be sold is forwarded by the shipper to the auction company and received some days in advance of the car. The cars are unloaded during the night and the produce systematically arranged in "lines;" i.e., citrous fruits, all of one variety, brand, and size are placed in a separate pile. The top package is opened for inspection. At a definite time, the wareroom is opened to buyers to permit an inspection of the produce before selling begins. Each buyer is provided with a list or catalogue which is compiled by the auction company from the car manifests received in advance, and contains a list and brief description of the produce to be offered for sale.

The following page from a fruit auction catalogue (reduced in size) will require some explanations:

LINES	MARKS	DESCRIPTION
	Ontario Cucamonga Fruit Ex.	Cal. Fruit-Growers' Ex. D. D. Black, Dist. Mgr.
		S. F. R. D. Car 11191 Upland Ventilated Lemons
355	240	8 Jumbos
356	270	13
357	300	1
358	300	148 Boxes
359	360	68
360		
361	Monogram Brand (Red Ball) 240	1 Jumbos
362	270	5
363	300	67 Boxes
364	360	25
365		

The heavy figures to the left indicate the "lines," and each "line" means a certain number of packages which are grouped by themselves in the warehouse and marked with a large chalk-mark on the floor in front of the pile, this number on the floor corresponding to the "line" number in the catalogue. The name and small label appearing under "lines," and "marks" correspond to those upon the packages and serve to assist buyers who are not familiar with the English language in identifying the fruit and catalogue description. In the column "marks" is given the size of the package or the number of fruits it contains; under "description," by whom it is shipped, the car number, and under what shipping conditions. (In this case "ventilated;" it might have been "iced" or "precooled.") This is important to the buyer as often the conditions under which the fruit has been shipped may be closely related to its condition, appearance, and subsequent keeping quality.

The blank spaces in the "description" column are used by the buyers to make memoranda on the condition, grade, and value, and used for reference as the selling proceeds.

At a definite time, the buyers assemble in the auction-room. The auctioneer announces any corrections to the catalogue which may be necessary and opens the whole page for sale, and the highest bidder may take his choice of any "line" or "lines" on the page. As these are sold, each man scratches them off, and the remainder of the page is then thrown open for bids. The buyer who bids highest will choose the best "line" or "lines" on the page. The selling is started again and the highest bidder takes the best remaining "line," and this continues until the page is sold. Usually the rules of the auction company require sales of not less than ten large or twenty small packages unless the number in the line may be less.

(f) *Local auctions.*

Produce is sometimes sold by ordinary auction at the shipping station. This local auction method, as it may be designated, became an important method in marketing peaches in the Catawba Island district of Ohio. It is reported to have originated with an attorney, as he observed the amount of time unnecessarily consumed by the buyers and growers trying to complete sales.

The method is simple and rapid. As the growers arrive at the shipping-stations, they line up their loads in order of arrival. The buyers stand upon a platform and inspect the fruit of each load as it comes to them and the auctioneer conducts the sale. The fruit is then delivered to the car, checked over and paid for by the buyer. The auctioneer's fee is paid by the grower. The extensive growers may load their own cars which would be sold in the same way, often bringing an extra price.

This system made it possible for the buyer to secure the variety and grade of fruit he desired and he could, in this way, more easily buy a carload that would be of uniform quality, or of any grade he wanted. The grower who had a superior grade of fruit or especially well packed would have it selected from the average run, and in this way might secure a better price. Sales could be made quickly and the time of the grower saved in a very busy season of the year. Combines of the buyers to hold the price down were possible, but could be broken by the growers refusing to sell on the auction and shipping the fruit themselves to commission men.

The method has recently been superseded in the Ohio peach-growing district by local coöperative associations that are successfully serving the needs of the growers.

(g) *Distributing agency.*

Within the past few years, the problem of distributing the large crops of produce has presented itself with increasing importance. Heavy crops of high quality fruits and vegetables have been successfully grown, but the task of getting them distributed to the consumer in a sound wholesome condition at a reasonable price has been the greatest problem. All of the usual ways of marketing have been used, but additional ways have been devised and have come into practice.

There are several types of distributing companies or agencies and newer ones are continually being devised, formed, and put into operation. One type is for several coöperative associations to unite and hire a salesman to assist their manager to get in communication with a large number of markets and consuming centers and in this way secure a wide distribution for the produce.

One type of distributing agency may be described as a company that receives carlot shipments of various kinds of produce from any point in the country, but especially from local coöperative growers' associations, and sells it through its selling agents who are located in all of the important markets in the country, but managed from one or two central offices. It is possible, under such a system, to secure a more even and desirable distribution of produce as the local selling agents keep in close communication with the main office. In the shipping season, the agency will have representatives at the shipping stations to assemble, inspect and forward the carlots upon telegraphic advice from the main office, who in turn are advised daily as to the general market conditions and prospects by the selling agency.

Shipments started from the producing center to a certain selling market may be diverted to some other market upon instructions received from the central office, and in this way an over or an under supply in any market may be avoided. After the sales are completed, the returns are rendered to the grower through the shipping agents.

Such a distributing system effectively and honestly operated will relieve the grower and local coöperative association of the difficulty and expense of marketing their crops, giving them their entire time for the details of the production and packing. A large force of capable selling agents to study the needs of many local markets should be competent to assist in distributing large quantities of produce in an efficient way.

Coöperative associations.

Groups of fruit- and vegetable-growers have formed coöperative associations with the idea of securing better results by working together in the packing, shipping and selling of their products rather than by operating independently.

The coöperative idea and spirit were first and most highly developed among the fruit-growers on the Pacific coast and other western regions. This may be accounted for because of the distance from the greatest consuming centers, making large shipments necessary from the standpoint of economy; the general uniformity of the crops grown, and the fact that many growers depend entirely upon one or two specific kinds of crops for their income; and possibly that the western growers might have been quicker to see the advantages of such a scheme of marketing.

Without question, more coöperative associations of fruit- and vegetable-growers have resulted in failures than successes, but the spirit of coöperation is strong and may be said to be growing, and the mistakes of the past are used to guide the future.

A coöperative association should be a non-profit organization. Membership should be open only to actual producers, and when a member ceases to be a producer he ought to be required to dispose of his share in the association. Many organizations, standing under the name of coöperative associations, are in reality owned and managed by a few men (not always growers) exclusively for profit.

The organization of a coöperative association adapted to the requirements of a body of fruit- or vegetable-growers is not elaborate nor difficult. The growers who desire to form an association may assemble and, after choosing officers and a board of directors (frequently five) from among their own number, are ready to select a name for the organization, adopt a constitution and by-laws and make rules and regulations respecting the management of the association. Contracts should be made between the association and every member, and all obligations upon both sides specified. Membership certificates or shares of stock are sold and the voting power of the members arranged. This may be the same for each member, but sometimes is based upon the acreage of the member's crop, or the quantity of produce shipped by him the previous season.

The board of directors hire a general manager, usually upon a stated salary, but in some cases for a percentage of the gross receipts, or in a few cases, the number of packages handled. His chief duty is to look after details and enforce the regulations adopted by the association. The board of directors usually decide upon the ways of grading, packing, shipping, names of brands and such matters (often methods of harvesting and time of harvesting). It is thought that this will lead to uniformity and attractiveness in the packed product.

The details of the management may vary with the aim of the members and officers, the locality and the commodity handled. There may or may not be a central packing-house where the fruit of the members is delivered for inspection, grading and packing. With some fruits, as citrus, it may be imperative, but with highly perishable fruits, as strawberries, it may be very undesirable. Without a central packing-house, packing must be done in the field by each member, but more efficient inspection and grading is possible at a central packing-house, and the result is that a more uniform product can be prepared. When the packing is done in the field by the individual members, the inspection must be done by an inspector hired by the association and under the direction of the general manager or board of directors. He usually does this work at the loading-station, and obviously cannot do as thorough work as could be done at the central packing-house. In some associations the inspectors give demonstrations and instructions to the members before the crop is ready to harvest. When this is done, the requirements and desires of the association are better understood by the individual. This practice is especially valuable at the beginning of a new organization, or among new members.

After the produce is properly packed and loaded into suitable cars, it is forwarded to the marketing point. The selling may be accomplished through agents employed by the association or be turned over to a commission firm, a distributing agency or sold to a dealer or consumer. Returns are made to the grower upon the pro rata basis known as "pools." The price received for all of the same kinds of produce shipped within the specified time, a day, week, two weeks, month or season, is "pooled." The operating expenses are deducted and the remainder divided upon the basis of the amount of each grade or brand of produce contributed by each member. Differences and dissatisfactions may arise over the "pool" system among the growers. The produce of one member may be sold in Minneapolis at a much better price than was realized from the produce of his fellow member in St. Louis.

In addition to the advantages that may be secured by disposing of produce through a successful coöperative association, is the large and important feature of the possibility of the management buying many supplies needed by the association members in large quantities, selling them to the members without profit. The saving thus secured on some supplies and in some regions is considerable and a strong argument in favor of a coöperative organization.

The reader who is specially interested in these associations, should secure from them copies of their constitutions and by-laws. These documents are now published, as examples, in many reports and books.

(a) *A California organization.*

The California Fruit-Growers' Exchange is the largest and most highly developed coöperative association of fruit-growers probably in the world. The form of organization is interesting and unique. About 12,000 fruit-growers of California are engaged in the production of citrous fruits and over 60 per cent are members of the California Fruit-Growers' Exchange,—a coöperative organization to provide facilities for these growers to distribute and market their fruit. There are three distinct divisions to the organization: (1) the local exchange; (2) the district exchange; (3) the central exchange. Each division has a clearly defined function and all are intimately related.

The local exchange.—There are about 150 of these local associations or exchanges located in the growing regions. They are non-profit corporations organized under the laws of California. Stock is issued to each member in proportion to his bearing acreage, to the number of boxes he ships, or in equal amount to each grower. The management is in the hands of a board of directors chosen from among the growers. A packing-house is owned or leased and properly equipped. No profits are accumulated nor dividends declared.

As the fruit is assembled in the packing-house, that of each member is kept separated until it is inspected and graded, which gives a basis for making the returns upon the "pool" system. An association may market any part of the crop at any time during the picking season they desire and, in some cases, this privilege is extended to the individual members.

The length of the "pool," whether a week or a month, depends upon the desires of the association. Each association has a brand name for each grade of its fruit, and this name and label is the exclusive property of the association. When a carload is ready for shipment, it is marketed through the "district exchange" of which the local association is a member.

The district exchange.—The local exchanges are federated into seventeen district exchanges, which are non-profit corporations. There may be one or more in a community, depending upon local conditions. Their function is to act as a clearing-house in marketing the fruit for the local exchanges through the California Fruit-Growers' Exchange and to act as a medium through which most of the business relations between the Exchange and local associations are handled.

The district exchange officers order the cars from the railroad and see that they are placed at the various local exchange packing-houses. They keep a record of the cars shipped by each local association, with their destination, and receive the money from sales through the head office and turn it over to the local exchanges. Other functions are to keep the growers informed through the head office of all phases of the citrous marketing business, and place this information before the local associations, where in turn it is passed on to the growers, and return the proceeds to the associations.

The central exchange.—The California Fruit-Growers' Exchange is a non-profit corporation formed by the seventeen district exchanges and managed by a board of seventeen directors, one from each district exchange. The headquarters is in Los Angeles. Its function is to furnish marketing facilities for the district exchanges at a pro rata share of the cost. The directors hire a general manager and assistants. Bonded sales agents for the principal markets of the United States and Canada are appointed and managed from this office. Telegraphic advice is received every day from these agents of the sale of each car, together with information on the conditions and prospects of the market. This information is sent daily in a bulletin form to the local associations. The business is on a cash basis and prompt accounting returns are made to the growers through the district exchange. Other functions are the attention to any litigation that may arise in connection with the marketing of fruit, handling all claims, conducting an advertising campaign and endeavoring to develop new markets. This work is supported by levying an assessment against each district exchange for the pro rata share of the expenses on a basis of the number of boxes shipped. In the Exchange, every shipper reserves the right to regulate and control his own shipments, to develop his own brands of fruit, to use his own judgment as to when and in what manner it shall be shipped and to what markets it shall be shipped, and the price he is willing to receive; reserving the right of free competition with all other shipments including the members of the same organization.

Membership in the Exchange is voluntary. A grower may withdraw from a local association at the end of the year; the local association may withdraw from the district exchange, and the district exchange may withdraw from the central exchange. One-third of the entire shipments are sold at public auction and the remainder through unrestricted private competition. There is no uniformity in price of the different brands.

The Exchange is organized in several divisions: Sales, Legal, Traffic, Advertising, Field, Insurance and Mutual Protection, and a Supply Department which furnishes materials used in packing-houses and groves at cost to members.

(b) *A Canadian organization.*

As the California Fruit-Growers' Exchange is the largest agricultural coöperation for marketing purposes in the United States, so the United Fruit Companies of Nova Scotia is a prominent example of successful coöperation by Canadian apple-growers. This company is located in the famous Annapolis Valley apple region of Nova Scotia. There are forty-eight coöperative companies in this Valley; forty are federated into a central association, which is incorporated under the name of the "United Fruit Companies of Nova Scotia, Limited." The membership of the subsidiary companies varies from ten to one hundred twenty, the average being about forty. Each company owns a warehouse or central packing-house where the fruit must be packed by experts under the direction of the company manager and an inspector sent from the central office, who has the authority to order repacking, if in his judgment it is necessary. Orchard- or home-packing by the individual members is not permitted. It is the business of each company manager to become acquainted with each member and with the type and grade of fruit he is growing. Before picking, the manager sends to the central office an estimate of the crop of his members and its condition. Pickers may be sent from the central office to assist the local growers. The picking and hauling is done under the direction of the local company manager. This rule has been found desirable to prevent large quantities of fruit from being delivered at the central packing-house unexpectedly. Fall apples may be hauled to the packing-house in unheaded barrels, as they are usually packed at once; but winter apples are delivered in tight barrels. Every barrel has the growers' name marked upon the side and a receipt is given for the quantity and variety delivered. The deliveries of every day are recorded in a book in which one or more pages are assigned to each member. On the left side are the series of columns, one for each variety, under which is recorded the date and number of barrels delivered. On the right page is a record of how these apples were graded or "packed out."

The business of marketing the entire output of all the subsidiary companies is performed from the central office, which is at Berwick. This office maintains and directs an organized force of salesmen. European sales are conducted through the London office and the South American business through the Buenos Ayres office. The apples of all the local companies are pooled and the returns made to all upon the average selling price of each grade of each variety.

Some of the advantages to the growers that have been brought about by the coöperation, in addition to better prices, are the convenience of an improved type of box-car especially adapted for shipping apples in extremely cold weather, and a shorter shipping time for transatlantic shipping, and better boats.

Coöperative buying is an important function of the association. The central office makes large purchases of supplies directly from the manufacturers, thus securing the lowest price, as all the cost of selling, bad debts and other expenses are eliminated. The supplies are shipped in carlots directly to the central packing-houses of the local companies and, upon arrival, the members are advised and come with their teams to haul home the goods they ordered. In 1914, over 300 carloads of fertilizers were purchased at a saving of $18,000 to the members; large quantities of other supplies were purchased, as pulp, heads, nails, grass, clover, vetch and oat seed, flour, feed, arsenate of lead, wire fence, lime-sulfur and tobacco sulfate.

As a further coöperative function, the central office handles all of the fire insurance business of the subsidiary companies of insuring the packing-houses and contents, thus saving the commission previously paid to agents. A weekly newspaper called the "Coöperative News" is published from the central office.

The total selling expenses in 1914 were exactly 4 cents a barrel, or 1⅓ per cent on the volume of business.

For discussions of methods of sorting, grading and boxing fruits and other products, see the article *Packing*, Vol. V.

H. J. Eustace.

MARKHÀMIA (after C. R. Markham, who intro. the Cinchonas into India). *Bignoniàceæ*. A genus of 10 African and 2 Asiatic tropical evergreen trees or shrubs with large opposite odd-pinnate lvs. usually with pseudostipules in the axils, glabrous or pubescent: fls. in large terminal or axillary panicles; calyx spathe-like, splitting on one side; corolla tubular-funnelform, usually yellow with red or purple stripes inside; stamens 4, included, with spreading anther-cells; ovary with 4 rows of ovules in each cell: caps. linear, loculicidally dehiscent into 2 leathery valves, the true septum small, with a much larger false septum in its middle parallel to the valves; seeds oblong, winged at the ends.—Only the following species is cult. in S. Calif. and it is, even without fls., a handsome foliage plant. Cult. like Radermachia, to which it is closely related.

platýcalyx, Sprague. Tree, to 40 ft.: lvs. ½–1 ft. long, with suborbicular pseudostipules ½–1 in. broad in the axils; lfts. 5–9, short-stalked, elliptic-oblong to obovate, abruptly and obtusely acuminate, entire or serrate, lepidote, 2–5½ in. long: panicles terminal or axillary, rather dense; calyx boat-shaped, pubescent and lepidote, ¾in. long; corolla yellow, inside striped red, lepidote, inside and outside, veined, the tube 1¼–1½ in. long, the elliptic-obovate lobes about ½in. long: caps. linear, 1 ft. long. Uganda. H.I. 28:2800.—Said to yield the finest timber in Uganda.

Alfred Rehder.

MARROW, VEGETABLE: *Squash.*

MARRÙBIUM (ancient name, referring to the bitter qualities). *Labiàtæ*. Hoarhound. Horehound. A familiar aromatic herb.

Marrubium comprises perennials branched from the base, mostly silky or woolly, with wrinkled and crenate or cut lvs., and many-fld. axillary whorls of small white or purplish fls.: calyx tubular, 5–10-nerved and with 5 or 10 awl-shaped teeth; corolla 2-lipped, the upper lip erect and notched or entire, the lower spreading and 3-cleft; stamens 4, didynamous, not exserted; ovary deeply 4-lobed (making 4 smooth nutlets), the style 2-lobed.—Species 30–40, in Eu., N. Afr. and extra-trop. Asia.; one widely naturalized in the U. S.

vulgàre, Linn. Common Horehound. Height 1–3 ft.: sts. ascending, woolly or tomentose: lvs. ovate to round-ovate, stalked: calyx with 10 recurved teeth, the alternate ones shorter: fls. whitish. Summer.—Now found as an escape from gardens in waste places of nearly every country of the world. Horehound is used in large quantities for confections and medicines for coughs and colds.

candidíssimum, Linn. Foliage silvery gray, flannel-like, the branches long: perennial: lvs. ovate, crenate: fls. whitish, in large many-fld. fascicles; calyx-teeth subulate, rigid, spreading, usually 5, but sometimes 6–10. Spain to Caspian Mts.

L. H. B.

MARSDÈNIA (William Marsden, 1754–1836, wrote a history of Sumatra). *Asclepiadàceæ*. Mostly twining shrubs of warm countries, a few of them sometimes planted for ornament; some of them medicinal and yielding dye and fiber.

The genus is allied to Stephanotis, which has large white fls., while those of Marsdenia are smaller and usually purplish, lurid, greenish or pallid. Lvs. opposite: cymes umbel-shaped, simple or branched, terminal or axillary; calyx 5-parted; corolla bell-, urn- or salver-shaped; lobes narrow or broad, overlapping to the right; crown of 5 scales: seeds comose, in a more or less fleshy follicle.—In tropical and subtropical countries around the world, the species probably being nearly 100. Genus rather heterogeneous.

Róylei, Wight. Lvs. 3–6 in. long, 2–4 in. wide, ovate-cordate, acuminate, pubescent or tomentose beneath; petioles 1½–2 in. long: cymes 1–1½ in. across; fls. 3–4 lines in diam.; corolla somewhat bell-shaped; lobes large, fleshy, pubescent; stigma not extended beyond the anthers. Himalayas, 4,000–5,000 ft. altitude.

macrophýlla, Fourn. Woody twiner: lvs. large, oval, acuminate, the base truncate or subcordate, glabrous, somewhat glaucous beneath: calyx deeply cut, the segms. large, oval, obtuse; corolla-tube glabrous, the limb spreading, and the lobes oval and short-ciliate on margin. Brazil; Paraguay (?).—Offered in S. Calif.

verrucòsa, Decne. Twining, the branches thick: lvs. broadly or nearly orbicular-cordate, abruptly acuminate, glabrous, glandular at top of petiole: fls. many, in a short cluster; corolla-lobes ovate, somewhat emarginate, barbed; lobes of corona lanceolate and fleshy. Madagascar.—Offered abroad.

M. Cundurángo, Reichb. f. (Gonolobus Cundurango, Triana), of Ecuador and Colombia, yields the medicinal condurango bark: liana: lvs. round-oblong, acute, hairy beneath: fls. whitish, the corolla somewhat campanulate.—*M. erécta*, R. Br., is fairly hardy at Arnold Arboretum: fls. white, fragrant: lvs. cordate-ovate. S. E. Eu., Syria.—*M. Ímthurnii*, Hemsl. A vigorous twining shrub with long hanging branches and fls. resembling a Hoya: lvs. ample, long-petioled, rather thick and soft and bullate (blistered), cordate-ovate: fls. about ½in. across, purple, hairy, in dense globular very short-stalked axillary umbellate cymes. British Guiana. B.M. 7953.

L. H. B.

MARSHÁLLIA (Humphrey Marshall, wrote "Arbustum Americanum," 1785, the first American work on trees and shrubs; also founded one of the first American botanic gardens). *Compósitæ*. Perennial North American herbs, useful in outdoor planting.

Tufted plants, growing about 1 ft. high, with entire lvs. and scapes bearing solitary rayless heads about 1½ in. across: involucre hemispheric or bell-shaped, its bracts narrow and green; fls. all perfect and fertile; pappus of 5–6 acute or acuminate scales.—About a half-dozen species. All may be grown in the open border in the N. and they may be prop. by division in the spring. Supposed to suggest the scabious. The blue anthers give a peculiar effect to the fls.

cæspitòsa, Nutt. Tufted, glabrous: lvs. spatulate-linear; upper ones linear: bracts of the involucre linear: disk-fls. pale rose or white: seeds inversely pyramidal, villous on the angles. Limestone soil, Mo., to Texas. B.M. 3704.

grandiflòra, Beadle & Boynton. Like the next except that the st.-lvs. are oblong-lanceolate and acute or obtuse. Moist soil, Pa. to W. Va. and N. C.

trinérvia, Walt. St. simple or branched, usually leafy about half way up: lvs. acuminate at the apex, narrowed to a practically stalkless base: fls. purplish sometimes whitish, pink; bracts of the involucre linear-lanceolate. Va., south.

N. Taylor.†

MARSH MALLOW: *Althæa officinalis.*

MARSÍLEA (Giovanni Marsigli, Italian botanist of last part of the 18th century, or Aloys Ferd., Graf von Marsigli, 1658–1730). *Marsileàceæ*. Aquatic flowerless plants related to ferns (about 40 species), with lvs. like 4-lvd. clover or oxalis, one species of which, **M. quadrifòlia,** Linn., is sold and is also run wild in the eastern states. It is a creeping plant, rooting in the mud on the margins of ponds and making an attractive cover. The petioles grow 3–5 in. tall, or taller in the water, and bear at the apex 4 bright green obcuneate or triangular lfts. The sporocarps or frs. are nearly sessile at the base of the petioles. Prop. easily by pieces of the runners, and is likely to become a weed. The young lfts. close at night. Eu. and Asia. Mn. 6, p. 107. **M. Drúmmondii,** A. Br. (Fig. 2327), is a greenhouse species needing moderate temperatures and pot cult. with abundance of surplus water in saucers or even set in a tank, partly submerged. Under the best conditions the long clover-like lvs. may reach a length of 18 in., and form a very attractive plant. The stalks and lfts. are covered with whitish hairs; the spores are borne in cases on separate stalks an inch or so long.

R. C. Benedict.

MARTINÈZIA (Rev. Dr. Baltasar Jacobo Martinez Companon, archbishop of Santa Fé, who sent many early collections of plants from Peru). *Palmàceæ,* tribe *Bactrìdeæ.* Ornamental feather-leaved palms, with spiny ringed trunks.

Leaves pinnate, the segms. broad, wedge-shaped, alternate or grouped, the apex truncate and ragged; petioles and rachis spiny, as are also the spadices and spathes of the infl.: fls. rather small, the calyx with 3 segms.; stamens 6, inserted in the disk: fr. globose, 1-celled, orange, scarlet or rose-pink.—Species about 8. Trop. Amer. G.C. II. 26:491.

Martinezias are beautiful palms, and make fairly good house plants but their spiny character is against their popularity. They must have a stove temperature. They do not require a great amount of soil. Light sandy loam, with plenty of sharp sand, is best. They need abundant moisture. They sometimes flower in cultivation, but the four kinds given below are distinct by their foliage and spines. Like all armed palms, they are slow to germinate, but after the first or second year they grow fairly fast. The commonest and best kind is *M. caryotæfolia,* which has fewer spines than the other species and, unlike many other palms, shows its true leaves at a very early stage. It resembles the fish-tail palms (Caryota), but the leaves are a lighter green and usually larger. *M. erosa* makes a better specimen at 5 to 6 feet than when small. It is much more jagged at the tips of the leaves. Being very spiny all over, it is less desirable. *M. Lindeniana* is more like the first. The spines are longer but not very numerous. *M. granatensis* is of coarser habit and slower growth, and desirable only for large collections. (H. A. Siebrecht.)

2327. Marsilea Drummondii.

A. *Lvs. divided into segms.*

B. *Segms. in groups.*

C. *Apex of segms. 3-lobed.*

caryotæfòlia, HBK. Sts. at length 30–50 ft. high but usually not over 6 in. thick: lvs. few, 3–6 ft. long, light green; lfts. in groups, 6–12 in. long, 4–6 in. wide at the apex: st., petioles, rachis and nerves below, densely clothed with long black spines: spadix about 18 in. long, appearing between the lvs.: fr. yellowish red, about ¾in. long. Colombia. G.C. 1872:181. B.M. 6854. F.R. 2:49.

CC. *Apex of segms. with a point projecting from the upper margin.*

Lindeniàna, Wendl. Sts. 9–15 ft. high: pinnæ in opposite groups of 4–6, the groups widely separated, long-wedge-shaped, 10–14 in. long, 8–10 times as long as broad, with a short, projecting point at the upper margin, the nerves ciliate-spiny toward the end; petiole densely covered with grayish brown hairs, with many rather large black spines 1–2½ in. long; rachis is also spiny above and below; midnerve of each segm. a trifle shorter than the lower margin and spiny beneath, like the rachis and lateral nerves: lvs. dark green above, lighter beneath; terminal segm. broadest: fr. rose-red. Mts. of Colombia, at an altitude of 6,000 ft.

BB. *Segms. in 2–4 pairs.*

eròsa, Lind. Lvs. with 2–3 pairs of narrow lfts. at base and a pair of broader ones at the apex, all oblique at the apex, bearing long, brown, needle-shaped spines on the veins and midrib; rachis cylindrical or obtusely angled, mealy, clothed with spines like those on the lvs. W. Indies. G.C. 1872:1297.

AA. *Lvs. bifid at the apex.*

granaténsis, Hort. (*M. granadénsis,* Hort.). Lvs. roundish oblong or roundish ovate, entire at the base, bifid at the apex, evenly toothed along the edges; petioles and rachis with dark brown, needle-shaped, spreading or reflexed spines, ½–1 in. long. Colombia.

M. truncàta, Brongn. Trunk about 20 ft.: lvs. 4–5 ft. long, spreading, the petiole and trunk covered with brownish black spines; lfts. smooth, prominently veined and beautifully dark green.—A fine showy Bolivian species scarcely known in the trade.

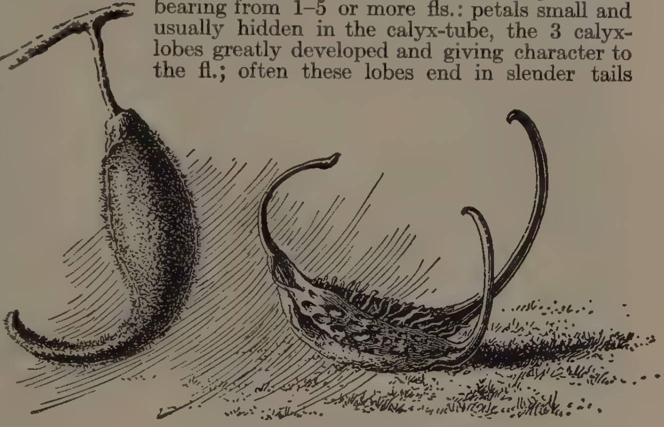
Jared G. Smith.
N. Taylor.†

MARTIUSÉLLA (after K. F. Ph. von Martius, German botanist, 1794–1868; traveled in Brazil 1817–20, wrote Historia Naturalis Palmarum and started the monumental work, Flora Brasiliensis, continued after his death by A. W. Eichler and I. Urban). *Sapotàceæ.* An evergreen small tree from Brazil with large alternate serrate lvs.: fls. small in axillary clusters; calyx 5-, rarely 4-parted; corolla rotate, 5–6-lobed; stamens 5, inserted at the base of the corolla opposite to the lobes and nearly as long as the corolla; sometimes with staminodes between the petals; ovary 5-celled with short style: fr. subglobose, 3–5-seeded; seeds compressed; cotyledons thin. Closely allied to Chrysophyllum which is chiefly distinguished by its smaller entire lvs., the longer corolla-tube, shorter stamens and the thick cotyledons, and also by the much-branched habit. The only species is **M. imperiàlis,** Pierre (*Theophrásta imperiàlis,* Lind. *Chrysophýllum imperiàle,* Benth. & Hook.). See also p. 767, Vol. II. Strict and simple, to 20 ft. high or more: lvs. obovate-oblong to oblong-oblanceolate, rounded at the apex, serrate with strong parallel veins, stellate-pilose beneath at first, becoming glabrous, 8 in. to 3 ft. long: fls. yellowish green, ¼in. across, pedicelled, in axillary sessile clusters: fr. subglobose, 1⅓ in. long, with a hard thick flesh; seeds chestnut-brown, lustrous, about 1 in. long and ¾in. wide. Brazil. B.M. 6823. I.H. 21:184. Gt. 13:453.—It can be grown outdoors only in frostless regions; sometimes cult. in greenhouses for its large handsome foliage. It flowers very rarely in cult., flowering first in 1885 after it had been in cult. for 40 years. Prop. is by seeds or by cuttings in March when the new growth is starting; the upper part of the plant is cut into as many pieces as there are lvs., the cuts being made just below the base of the lvs.; the cuttings are inserted in sand under glass with bottom heat; they usually take a long time to form roots.

Alfred Rehder.

MARTÝNIA (John Martyn, 1699–1768, professor of botany at Cambridge, botanical author). Including *Proboscídea*. *Martyniàceæ*. Coarse annuals and perennials from the warmer parts of America, a few of which are cultivated for pickles or for ornament.

Rank branchy plants of heavy odor, viscid-pubescent, mostly sprawling on the ground: lvs. large, likely to be opposite and alternate on same plant, petioled, broad and subcordate, entire or lobed: fls. large and funnelform-campanulate in short loose terminal racemes; calyx more or less swollen-campanulate, deeply and unequally 5-parted, often split on the anterior side; corolla violet-purple, pale yellow or whitish mottled, oblique, decurved, the limb somewhat bilabiate but the 5 spreading lobes nearly equal; fertile stamens 2 in the genus Martynia as defined by Stapf (Engler & Prantl, Die Pflanzenfamilien, including one species apparently not in cult.), and 4 in the genus or group Proboscidea which is here included in Martynia and to which the cult. species belong; ovary 1-celled, the 2 parietal placentæ extended inward and meeting at the middle as if 2-celled: fr. a 2-valved caps., more or less fleshy, hairy, with a long curving beak; seeds large.—Species about 8, U. S. to S. Amer. The closely allied Craniolaria (which see, in Vol. II) is distinguished by the long slender corolla-tube (*Martynia Craniolaria*, Glox.=*Craniolaria annua*). The trade names need revision.



2328. Martynia louisiana. (×⅓)

Martynias are sometimes grown in gardens for their bright large flowers, abundant foliage and odd pods. They are treated as half-hardy annuals. They are also grown in the vegetable-garden for the small tender pods which are made into pickles the same as cucumbers. The plants grow 1½ feet or more high, and spread widely. They should be started in a hotbed in the North and transplanted to the open. In the middle and southern states seed may be sown in the open 3 feet apart each way where the plants are to remain. They need a warm open soil and sunny exposure. The fruits have a very distinct appearance by reason of the long-curved horn which splits from the top as the capsule hardens.

A. *Lvs. more or less lobed: fls. purple or reddish.*

fràgrans, Lindl. (*M. formòsa*, Vilm. *M. violàcea*, Engelm.). Annual: less stout than *M. louisiana:* lvs. roundish to oblong-cordate, somewhat lobed and wavy-toothed, 3–5 in. broad: corolla campanulate, 1 or 2 in. long and wide, fragrant, reddish purple to violet-purple. Texas, New Mex., Ariz., N. Mex. B.M. 4292. B.R. 27:6. R.H. 1843:529.

AA. *Lvs. sinuate or perhaps dentate, not lobed: fls. mostly whitish or yellowish but sometimes purplish.*

louisiàna, Mill. (*M. proboscídea*, Glox. *Proboscídea Jussieùi*, Steud.). UNICORN PLANT. PROBOSCIS FLOWER. Fig. 2328. Annual, the ascending or prostrate branches 2–3 ft. long: lvs. roundish, cordate, often oblique, entire or obscurely wavy-lobed, 4–12 in. wide: fls. 1½–2 in. long, dull white or yellowish with mottles or spots of purple or yellow within, the corolla nearly as broad as long, the lobes obtuse: fr. 4–6 in. long at maturity, the beak equaling or exceeding the body. Native from Ind. to Utah and to Texas and New Mex.; naturalized farther east and north. B.M. 1056. V. 3:151.—The picture (Fig. 2328) shows frs. one-third the size at full maturity. The right-hand specimen shows the woody part, after all the soft parts have been macerated.

lûtea, Lindl. (*M. montevidénsis*, Cham.). Annual, 1½ ft., the plant pale, glandular-pubescent: lvs. cordate-orbiculate, subdentate, 5–7-nerved: fls. few, in erect terminal racemes, large, greenish yellow outside and orange inside; corolla funnel-shaped, the tube constricted: caps. woody, boat-shaped, cristate on back, 2-beaked at apex, the beaks 2 in. long. Brazil. B.R. 934. Perhaps not in the trade. L. H. B.†

MASDEVÀLLIA (Joseph Masdevall, a Spanish physician and botanist). *Orchidàceæ*. Orchids, not showy, but odd and often grotesque.

Pseudobulbs none: lvs. variable in size, oblong to linear, thick, sheathing at the base: peduncles bearing from 1–5 or more fls.: petals small and usually hidden in the calyx-tube, the 3 calyx-lobes greatly developed and giving character to the fl.; often these lobes end in slender tails several inches long; lip of the corolla short, articulate with the base of the winged or wingless column, in some species sensitive; pollinia 2, without caulicles.—More than 150 species, inhabitants of the American tropics, and various hybrid and garden forms. The species of the *M. coccinea* group are relatively simple in form, but are usually prized for their brilliant coloring. Those of the *M. Chimæra* group are remarkable for their fantastic shapes. Of late years many new kinds have been intro., and the genus is somewhat confused as to the specific limits of the various forms. Masdevallias are polymorphous, and herbarium specimens do not show specific characters well. See "The Genus Masdevallia," by Florence H. Woolward (1896).

Cultural directions. (R. M. Grey.)

Masdevallias are found growing at high elevations, ranging from 6,000 to 12,000 feet above sea-level, in northwestern South America and Central America, with a few sparingly distributed elsewhere over tropical America. These regions are generally subjected to two rainy seasons annually, often with very short intermissions. The atmosphere, though somewhat rarified, is very humid, the temperature in the shade seldom rising above 65° F., and often dropping to 40° in some districts. Heavy fogs are frequent, especially in the fore-part of the day, and during the greater part of the year the under-vegetation is in a saturated condition; the high winds prevalent in these districts, however, counteract to a great extent any evil influence which might otherwise arise from it.

The heat of our summer makes it quite impossible to imitate wholly the above conditions, but with a proper house, such as is afforded odontoglossums of the crispum section, very satisfactory results may be obtained and the many species will be found of comparatively easy culture. A low, well-ventilated, half-span house of northern exposure, with an upright stone or brick wall on the south side, is best adapted to them. The house should be provided with canvas roll-shading, supported on a framework elevated 15 or 18 inches above the glass in order that the cool air may pass freely beneath it. This will help to guard against solar heat during summer. Houses built partly below ground are not to be recommended, as the atmosphere soon becomes stagnant and inactive, causing the leaves to fall prematurely. When it is convenient, solid beds are preferable; benches, however, will answer the purpose very well, and when used should be covered about 2 inches deep with sifted ashes, sand or gravel; the benches and floors should be hosed down once or twice daily to afford all the cool moisture possible.

2329. Masdevallia coccinea. (×⅙)

In winter the temperature should range between 50° and 55° F. at night and about 60° during the day or 5° more on mild days, with weak solar heat and ventilation. Artificial heat must be dispensed with as early in spring as possible, and during summer the temperature kept as low as the weather will permit, ventilating freely, especially at night, when a light syringing overhead will also prove beneficial. Midday syringing in hot weather is often injurious and should be done with caution if at all. More benefit will result from hosing down the shelves and paths at intervals of three or four hours, as it will help to reduce the temperature.

Masdevallias need a great deal of water at the roots at all seasons, and the soil should never be allowed to dry out, as they have no fleshy pseudobulbs to protect them against extreme changes. Light syringing overhead during winter and spring in fine weather will assist in checking thrip and red-spider, and a weak solution of tobacco may be added with good effect.

The best season for repotting and basketing the plants is during November and December, and the best general compost is a mixture of clean peat fiber and sphagnum moss chopped rather fine and well mixed, some sections requiring in addition a portion of chopped sod. About one-third of the space should be devoted to clean drainage consisting of either broken charcoal or potsherds.

M. coriacea, *M. elephanticeps*, *M. Peristeria*, *M. Reichenbachiana*, and kindred species, grow best in small pots, and should have one-third chopped sod added to their potting compost. *M. macrura*, *M. Schlimii*, *M. tovarensis*, *M. amabilis*, *M. coccinea*, *M. Veitchiana*, *M. triangularis*, *M. polysticta*, *M. muscosa*, and the numerous other allied species, grow equally well in either pots or baskets, but should the latter be used it would be well to add a small portion of chopped sod to the compost to make it more firm and less porous; the sod has a cooling effect on the roots. *M. bella*, *M. Carderi*, *M. Chestertonii*, *M. Chimæra*, *M. Houtteana* and their allies nearly all have pendulous flower-scapes, and should be suspended from the roof in baskets in a compost of equal parts chopped peat-fiber and live sphagnum, with a little leaf-mold added. The flower-scapes often penetrate through the compost; for this reason little or no drainage should be used, as it may retard their progress.

To increase the stock the plants must be divided during the early winter; this will give them a chance to reëstablish themselves before the following summer. They must not be broken up into too small pieces, as it has a tendency to weaken them.

REVIEW OF THE SECTIONS.

SECTION I. Scape 1-fld.; calyx-tube rather narrow, tubular or somewhat funnel-shaped; labellum plane .... Species	1–7
SECTION II. Scape 1-fld.; calyx-tube broad, gibbous or basin-like; labellum plane .... Species	8–24
SECTION III. Scape several-fld.; labellum plane and narrow .... Species	25–37
SECTION IV. Scape mostly 1-fld., pendent or suberect; labellum saccate, or at least much broadened; tails very long .... Species	38–44
SECTION V. Scapes 1-fld. This section differs from all the others by the subterete lvs., and in having the tails inserted below the apex of each lateral sepal .... Species	45

SECTION I.

A. *Calyx-lobes glandular with minute papillæ* .... 1. **Veitchiana**
AA. *Calyx-lobes not glandular.*
  B. *Tail of the dorsal lobe hanging forward* .... 2. **militaris**
    3. **rosea**
  BB. *Tail of the dorsal lobe erect and straight* .... 4. **amabilis**
    5. **Davisii**
    6. **Barlæana**
  BBB. *Tail of the dorsal lobe reflexed and flexuous* .... 7. **coccinea**

1. **Veitchiàna**, Reichb. f. Tufted: lvs. 4–6 in. long, narrow: peduncle erect and slender, 1 ft. or more, with 2 or more bracts (the upper one remote from the fl.); calyx with bell-shaped tube, the expanding lobes 3 in. across, orange-red, with purple shades, glandular-hairy, abruptly contracted into short, narrow tails; petals white, hidden. Peru. B.M. 5739. C.O. 4*a*. Var. **grandiflòra**, Hort., has a dense hairy covering on the dorsal lobe of calyx; and also on the outer part of the lateral lobes, the inner part orange-scarlet. C.O. 4*b*.

2. **militàris**, Reichb. f. & Warscz. (*M. ignea*, Reichb. f.). Much like the last, but differs in having elliptic or elliptic-obovate lvs., which are long-petioled, and in the lateral calyx-lobes being only prominently pointed, not tailed, the dorsal lobe very narrow and hanging forward between the other two: color orange and

scarlet; petals white, exceeding the column. Spring. Colombia. B.M. 5962. I.H. 26:333. G.M. 52:283. C.O. 2. Var. **Massangeàna,** Hort. Lateral lobes longer: fls. larger. Var. **Bóddærtii,** Hort. Calyx yellow; lower lobes shaded with red on the upper surface. I.H. 26:357. Var. **grandiflòra,** Hort. Fls. rounded; lateral sepals brilliant vermilion, bordered with crimson and suffused with purple. Var. **supérba,** Hort., is advertised.

3. **ròsea,** Lindl. Lvs. oblong-spoon-shaped, keeled: peduncle drooping and slender, bearing a single fl.; calyx-tube 1 in. long, red and violet; calyx-lobes rose-lilac, with red tails; petals yellow, the lip hairy at the apex. Ecuador. G.C. III. 16:657. O.R. 4:113; 11:25. July, Aug.—A pretty and free-flowering species.

4. **amábilis,** Reichb. f. & Warscz. Lvs. 4–5 in. long, oblong- or spatulate-lanceolate, about half the length of the erect, usually 1-fld. peduncles: fls. varying from purplish crimson to yellow; lobes ovate-triangular, the lateral ones with short tails and the dorsal ones with a long and ascending tail; petals narrow, yellowish, longer than the column. Peru. Sept.–Dec. Var. **lineàta,** Lind. & André (var. *striàta,* Hort.), has yellowish fls., tinged and striped with red. I.H. 22:196.

5. **Dàvisii,** Reichb. f. Densely cespitose: lvs. oblong-lanceolate, 6–8 in. long, petioled, blunt at the apex: peduncle erect, about 10 in. long; calyx large, brilliant yellow, obscurely veined with deeper yellow; dorsal lobe triangular-ovate, prolonged in a tail; lateral lobes oblong-ovate, larger, united to below the middle, terminating in short tails; petals longer than the column, nearly hidden in the calyx-tube, pale yellow, the labellum yellow, shaded and spotted with red, with 2 obscure keels. Peru. B.M. 6190. C.O. 1.

6. **Barlæàna,** Reichb. f. Lvs. spatulate, acute: peduncle slender, nearly 1 ft. long; fls. scarlet; calyx-tube curved; dorsal sepals short-triangular, produced into a long tail; lateral sepals larger, semi-ovate; petals ligulate, white. Peru.—Reichbenbach states that the lateral sepals run internally one in another; they are connate in a straight line.

7. **coccínea,** Lind. (*M. Líndenii,* André). Fig. 2329. Lvs. spatulate, obtuse or retuse, 6–10 in. long: peduncle 1 ft. or more long; calyx crimson-magenta; dorsal lobe with a small, triangular base, prolonged into a long tail; lateral lobes oblong-ovate, scarcely prolonged; petals white, longer than the column. May. Colombia. B.M. 5990. I.H. 17:42. F.M. 1872:28. Var. **conchiflòra,** Veitch. Fls. large; lateral lobes of labellum rotund, concave. Var. **Harryàna** (*M. Harryàna,* Reichb. f.). Lateral lobes of calyx oval, falcate, the tips usually crossing or turned toward each other. May. F.S. 21:2250. C.O. 7. Var. **armenìaca,** Hort. Fls. apricot-yellow, veined with red; throat of the tube yellow. Colombia. Var. **atrosanguínea,** Hort. Fls. large, with the lateral sepals crimson spotted with magenta, points falcate, turned toward each other. Colombia. Var. **cœrulëscens,** Hort. Lateral sepals broadly semi-ovate, apiculate, crimson-magenta spotted with bluish purple. Colombia. Var. **Gràvesiæ,** Hort. Fls. white. Var. **grandiflòra.** Fls. large, rose-purple. Colombia. Var. **Dénisonii,** Hort. BULL'S BLOOD. Fls. crimson-purple.

SECTION II.

A. *Habit of scape drooping or deflexed.*

16. **macrura**
DDD. *Fls. crimson*..................17. **calura**
BB. *Scape longer than the lvs.*
C. *Size of fls. rather small, with a broad, basin-like tube: plants dwarf.*
D. *Fls. mauve*..................18. **Shuttleworthii**
DD. *Fls. yellow, marked or spotted*...19. **xanthina**
20. **triangularis**
21. **Wageneriana**
DDD. *Fls. varicolored*..............22. **Estradæ**
23. **hieroglyphica**
CC. *Size of fls. larger, with a broad, deep, gibbous tube*............24. **elephanticeps**

8. **platyglóssa,** Reichb. f. Densely tufted: lvs. spatulate-lanceolate, narrowed into petioles, 3–4 in. long, as long as or longer than the drooping bracted 1–2-fld. peduncles: fl. small (1 in. long), pale yellow, nearly globular, the lobes pointed but not tailed, the dorsal one upcurved; ovary red; petals linear, as long as the column. Colombia (?) B.M. 7185.

9. **leontoglóssa,** Reichb. f. Tufted: lvs. oblanceolate, short-petioled, spotted beneath with red: peduncle deflexed, mostly shorter than the odd fls.; calyx narrow, the lobes gradually narrowed into fleshy tails or long points, semi-transparent, all of them greenish yellow outside and more or less hairy crimson-spotted within, the dorsal lobe not greatly unlike the others but often somewhat ascending; petals white with crimson lines. Colombia. B.M. 7245. C.O. 12.—The specific name ("lion-tongued") refers to the bearded lip.

10. **coriàcea,** Lindl. Lvs. linear-lanceolate, usually somewhat surpassing the erect, 1-fld., spotted peduncles, which are about 6 in. high: fls. fleshy, the calyx-lobes nearly equal and wide-spreading, triangular at base but gradually narrowed into long points or short tails; lobes greenish yellow and dotted crimson inside; petals white and crimson. Colombia. G.C. III. 21:95.—Lvs. 6–8 in. long, with purplish dotted petioles.

11. **cívilis,** Reichb. f. (*M. rùfo-lùtea,* Lindl.). Lvs. fleshy, linear, keeled, 5–6 in. long: peduncle less than 2 in. long, erect or nearly so; fls. solitary, rather large for the size of the plant, the deep calyx-tube purple at the base and yellow at the top, the long-pointed, flattened lobes yellow; petals small, white, the labellum dotted purple. Peru. B.M. 5476.

12. **Peristèria,** Reichb. f. Tufted: lvs. oblanceolate, sometimes retuse at the apex, 4–6 in. long, twice longer than the rather stout, erect, 1-fld. peduncles: fls. with 3 long, wide-spreading tails, which span 4–5 in., the tube somewhat gibbous beneath; back of the fl. greenish yellow; tails honey-yellow; throat and base of lobes spotted with crimson; petals linear-oblong, white. Colombia. B.M. 6159. F.S. 22:2346. C.O. 11.—Named from its resemblance to the dove orchid, Peristeria.

13. **ionócharis,** Reichb. f. Lvs. ovate-lanceolate, exceeding the erect peduncle: fl. whitish, purple-spotted at base, the lobes triangular-ovate, with yellow tails; petals cream-white. Peru.

14. **nidífica,** Reichb. f. Lvs. oval or oblong, about the length of or longer than the peduncle: fl. white, veined and dotted with crimson passing into yellow on the lobes, the lobes hairy and with long, slender tails, which are yellow in the lateral lobes and crimson in the dorsal lobe; petals white, with crimson lines. Ecuador.

15. **corniculàta,** Reichb. f. Sts. short and tufted: lvs. spatulate, very short-pointed, mostly exceeding the 1-fld. peduncles: fls. with yellow, inflated calyx-tube, which is spotted with brown and ribbed, bearing long, very slender brown tails; petals yellow. Colombia. Var. **inflàta,** Veitch. Paler in color, and with smaller spots; lobes broader and golden yellow. Colombia. B.M. 7476.

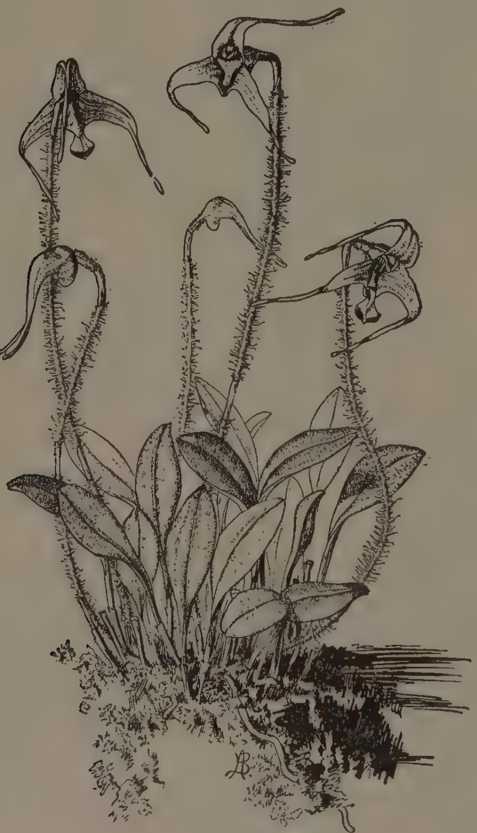
16. **macrùra,** Reichb. f. Sts. short and tufted, each bearing a solitary lf. and fl.: lvs. broadly spatulate or broad-oblanceolate, very obtuse or even retuse: peduncles 8–10 in. high, erect; fls. with 3 long tails, which span 8 in. from top to bottom; calyx-tube red-purple on the outside; lobes triangular-ovate in the basal portion, dull red and purple-spotted within, the cylindrical tails yellow, the lateral ones 7-ribbed; petals yellow, spotted brown. Colombia. B.M. 7164. C.O. 8.

17. **calùra,** Reichb. f. Lvs. mostly shorter than the peduncles, oblong-lanceolate: fls. glossy crimson, with slender, flat tails; dorsal lobe somewhat triangular at base, the lateral ones round-ovate; petals crimson, with white on tip and margins. Aug. Costa Rica.—A free-flowering species.

18. **Shúttleworthii,** Reichb. f. A small species, with lvs. only 2 in. long, on distinct petioles of equal length: peduncles several, 1-fld., sometimes overtopping the lvs.; fls. large (1 in. across and the tails 2–3 times as long), mauve, dotted with crimson; tails all yellow in the upper half, very slender, the upper one sometimes bent or hooked at the top; petals white. Colombia. B.M. 6372. I.H. 28:435. C.O. 6. Var. **xanthocòrys,** Reichb. f., has smaller fls. of pale yellow, dotted with brown or rose.

19. **xanthìna,** Reichb. f. Like the last, except that the fl. is yellow, with a purplish spot on the lateral lobes. Var. **pállida,** Hort., has fls. almost white. Colombia.

20. **triangulàris,** Lindl. Lvs. oblanceolate: peduncle erect, about 4 in. tall; fls. yellow, marked or spotted with purple, the tails dark crimson; lobes similar, triangular-ovate; petals white, the lip spotted with pink or purple and hairy. Venezuela.



2330. Masdevallia muscosa.

21. **Wagenerìana,** Lind. Very small, neat and attractive, tufted, 2–3 in. high: lvs. spoon-shaped: peduncles equaling or exceeding the lvs., nearly erect; fls. yellow and crimson-dotted, with slender yellow tails, the upper one inclined backward; lobes broad, cordate or ovate; petals yellow, odd in shape, the lip rhomboid and toothed. Venezuela. B.M. 4921.

22. **Estràdæ,** Reichb. f. Very densely tufted: lvs. and petioles 3 in. long, the blade broad, spoon-shaped, and often retuse at the apex: peduncle usually somewhat exceeding the lvs., erect, 1-fld.; fl. of marked colors—the upper concave lobe yellow at base and violet-purple above, the lateral lobes violet-purple at base and white or straw-colored above; tails filiform, yellow; petals white, very small. Colombia. B.M. 6171.

23. **hieroglýphica,** Reichb. f. Lvs. oval or oblong: peduncle short (about 3 in. long); fl. with tube yellowish at bottom, becoming whitish, marked with crimson; lobes triangular-ovate, all with long tails, the tail of the dorsal lobe hanging forward and marked with purple at its base; petals yellow. June. Colombia.

24. **elephánticeps,** Reichb. f. An odd species: lvs broad-spatulate, obtuse: peduncles 1 ft. long, erect; fl. single, parti-colored—the dorsal or upper lobe light yellow, the lateral ones ribbed and crimson; calyx-tube gibbous at the base below, all of them gradually produced into stout yellow tails (one of them often crimson), arranged so as to suggest the tusks and raised trunk of an elephant (whence the specific name). Colombia. F.S. 10:997. B.M. 7824. C.O. 10. Var. **pachysépala,** Reichb. f. (*M. Mooreàna,* Reichb. f.), has the dorsal lobe 3-nerved with crimson; tube spotted.

SECTION III.

A. *Lvs. covered with round papillæ: scape hairy*.......................25. **muscosa**
AA. *Lvs. smooth.*
B. *Fls. small, in many-fld. racemes; angles of the ovary crenulate or the petals toothed.*
C. *Color of fls. pale lilac*...........26. **polysticta**
CC. *Color of fls. white*..............27. **abbreviata**
28. **melanopus**
29. **caloptera**
CCC. *Color of fls. yellow*..............30. **pachyura**
BB. *Fls. larger, often expanding in succession: raceme several-fld.: angles of the ovary and petals entire.*
C. *Color of fls. white*..............31. **tovarensis**
CC. *Color of fls. yellow, dotted and shaded with brown or red.*
D. *Lateral sepals united, forming a boat-shaped cup*...........32. **Ephippium**
DD. *Lateral sepals nearly plane, at least not strongly cucullate.*
E. *Tails of the lateral sepals very short or none*.............33. **racemosa**
EE. *Tails of the lateral sepals long.*
F. *Lvs. broad, obovate-elliptic*..34. **Schlimii**
FF. *Lvs. oblong-lanceolate or oblanceolate.*
G. *Calyx-tube funnel-shaped, narrowed at the base*.............35. **Reichenbachiana**
GG. *Calyx-tube broader or gibbous at the base*.....36. **maculata**
37. **infracta**

25. **muscòsa,** Reichb. f. Fig. 2330. Lvs. oval-oblong, papillose: peduncle hairy, 3 times exceeding the lvs., with 1 yellow fl.; lobes triangular, with reflexed tails; petals narrow and yellow with a brown line in the center, the lip bearing a raised yellow disk and moving upward with a jerk when this disk is touched. Ecuador, Colombia. O. 1913:105.—Fls. ½in. across. See Leavitt, Plant World, April, 1906, from which Fig. 2330 is adapted.

26. **polystícta,** Reichb. f. Densely tufted: lvs. narrow-spatulate, obtuse and often retuse: peduncle exceeding the lvs., about 8 or 9 in. tall and many-fld.; fls. pale lilac, spotted with purple, the margins of the

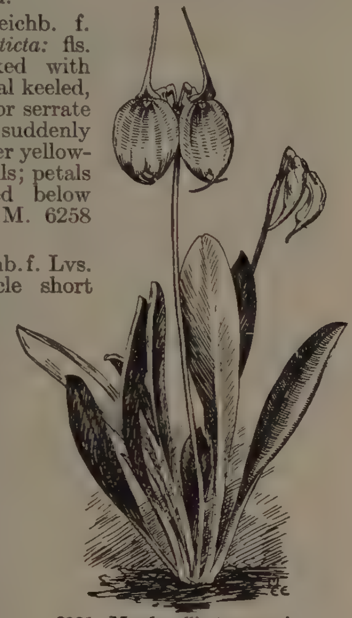
sepals ciliate but not serrate, the tails very slender and spreading (fl. 2–2½ in. across) and yellowish; petals spatulate and serrate. Peru. B.M. 6368. I.H. 22:199. R.H. 1880:250.

27. **abbreviàta,** Reichb. f. Lvs. oblong-lanceolate: peduncle many-fld., about 6 in. long; fl. white and freely dotted with red, the tails all deep yellow, the lobes serrate on the edges; petals white, longer than the column, serrate. Peru.

28. **melanòpus,** Reichb. f. Much like *M. polysticta:* fls. smaller, white specked with purple, the dorsal sepal keeled, the lobes not ciliate or serrate on the edges and very suddenly contracted into slender yellowish or dark-colored tails; petals linear-oblong, toothed below the apex. Peru. B.M. 6258 (as *M. polysticta*).

29. **calóptera,** Reichb. f. Lvs. oblong-ovate: peduncle short (5 or 6 in.), many-fld.; fl. white with crimson streaks, the tails all slender and orange; dorsal lobe keeled and somewhat hooded; the lateral ones ovate-oblong; petals white, crimson-keeled, serrate. Peru.

30. **pachyùra,** Reichb. f. Lvs. oval-oblong: peduncle erect, slender; calyx with triangular, short-tailed lobes, yellow, with transverse bars and spots of reddish crimson; dorsal sepal triangular, with a thick tail equaling the sepal in length; petals pale yellow. Ecuador. G.C. III. 22:255; 49:89. B.M. 8361.



2331. Masdevallia tovarensis. (×½)

31. **tovarénsis,** Reichb. f. Fig. 2331. Lvs. rather small, oblong-spatulate: peduncle 5 or 6 in. long, sometimes exceeding the lvs., 2-edged, several-fld.; fls. clear white and fragrant, the tails yellowish at the ends; dorsal lobe 1½ in. long, very narrow and produced into a reflexed tail; lateral lobes oval, gradually produced into tails shorter than that of the dorsal lobe; petals white. Dec., Jan. Colombia. B.M. 5505. I.H. 26:363. Gn. 48, p. 384. G.C. 1865:914; 1871:1421. J.H. III. 57:99. C.O. 13. O.R. 13:58.—One of the best of the genus.

32. **Ephíppium,** Reichb. f. (*M. trochìlus,* Lind. & André). Lvs. broad, oblong, 5–7 in. long: peduncle erect, about a foot long, sharply 3–4-angled, stout; calyx with the dorsal lobe cucullate, yellow, dotted with brown, ½in. diam.; lateral lobes united, forming a deep boat-shaped, chestnut-brown cup, with several ridges which are greenish outside; all the lobes pass into yellowish tails about 4 in. long; petals white. Colombia. B.M. 6208. I.H. 21:180. C.O. 9.—According to Index Kewensis, *M. trochilus* and *M. Ephippium* are distinct species. The former is described as having terete sts.

33. **racemòsa,** Lindl. (*M. Cróssii,* Hort.). Sts. creeping: lvs. oblong-ovate, much shorter than the several-fld. racemose peduncles: fls. membranaceous, orange with red lines, erect, 1 in. across, tails very short or none; lateral lobes ovate, blunt-pointed, curving outward so as to form a 2-lobed limb, the dorsal lobe ½in. long and pointed. Peru. C.O. 3.—Not a popular species. Requires a coolhouse.

34. **Schlímii,** Lind. Tufted: lvs. elliptic-obovate, petioled, a foot or less long, half shorter than the several-flowered peduncles: fls. dull yellow, mottled with bright brown, the tails yellow, about 1¼ in. across without the tails; tails 2–3 times longer than the body of the calyx-lobes, very slender; petals pale yellow, linear-oblong, equaling the column. Venezuela. B.M. 6740. G.C. II. 19:532.

35. **Reichenbachiàna,** Endres. Densely cespitose: lvs. oblanceolate, shorter than the several-fld. peduncles: fl. dark red on the outside, yellowish, with red veins on the inside, all the lobes with turned-back tails, the lobes triangular. Costa Rica.

36. **maculàta,** Klotzsch & Karst. Lvs. narrow-oblanceolate, nearly or quite equaling the erect several-fld. peduncle (which is 8–10 in. tall): fls. yellow-tubed, suffused or dotted with red, all the lobes produced into orange-yellow or greenish tails 2 in. long; lateral lobes crimson, with yellow on the margin, the tails drooping; petals yellowish. Venezuela. F.S. 21:2150.

37. **infrácta,** Lindl. Cespitose: lvs. oblong-lanceolate to narrow-lanceolate: peduncle about 6 in. long, several-fld.; calyx pink-purple; dorsal sepals cucullate, lateral sepals entirely united, forming a wide, gaping tube, with cucullate sides and apex, passing into slender, yellowish tails; petals whitish, dotted with pink-purple. Brazil. F.S. 23:2389.

SECTION IV.

A. *Fls. campanulate*.....................38. **Carderi**
AA. *Fls. not campanulate.*
B. *The fls. with cream-white ground, crimson-spotted*..................39. **Houtteana**
BB. *The fls. with yellow ground.*
C. *Free part of sepals orbicular, abruptly tailed*...............40. **radiosa**
CC. *Free part of sepals ovate, narrowed into the tail.*
D. *Inner surface of sepals glabrous*.41. **bella**
DD. *Inner surface of sepals with white hairs*................42. **nycterina**
DDD. *Inner surface of sepals with warts and hairs*............43. **Chimæra**
BBB. *The fls. with green or yellowish green ground*.....................44. **Chestertonii**

38. **Cárderi,** Reichb. f. Cespitose, with strong ascending foliage and hanging spotted 1-fld. peduncles: lvs. oblanceolate, 3–5 in. long: peduncles green-bracted, 3 in. long; fls. bell-shape, ¾in. across exclusive of the tails, white, with purple and yellow bars at the base; tails very slender and spreading, 1 in. long, yellow; petals small, white, linear-oblong and obtuse. Colombia. B.M. 7125.—A graceful and pretty species.

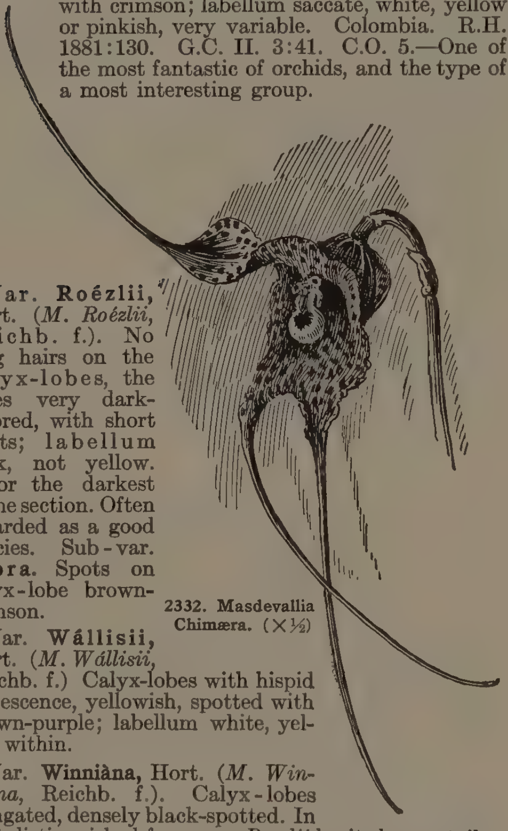
39. **Houtteàna,** Reichb. f. (*M. psittacìna,* Reichb. f.). Densely cespitose: lvs. linear to lance-linear, much exceeding the drooping or deflexed 1-fld. peduncles (which are 4–5 in. long): fls. creamy white, spotted with crimson, the long hanging tails brownish red; calyx-lobes semi-ovate to triangular, somewhat hairy (as are also the tips of the tails); petals white or pinkish. Colombia. F.S. 20:2106.

40. **radiòsa,** Reichb. f. Lvs. oblong or lanceolate: peduncle 2–3-fld., drooping or deflexed; fls. yellow, dotted and splashed with purple, the prominent tails all purple; petals yellow, purple-spotted, but the lip whitish. Colombia.

41. **bélla,** Reichb. f. Lvs. oblong-lanceolate, channelled, about 8 or 9 in. long, narrowing to the base: peduncle 1-fld., drooping or horizontal, ½ft. long, slender; fls. large and spider-like, triangular in outline, 3 in. across, with stiffish tails 4 in. long, of which the dorsal is recurved and the others standing forward and usually crossed, the fl. pale yellow, spotted with purplish or brown; petals white or yellowish. Colombia. Oct.–Dec. G.W. 4, p. 77. C.O. 14.—One of the best of the chimæras.

42. **nycterìna,** Reichb. f. Often confused with *M. Chimæra*, but a smaller and less showy plant: tufted: lvs. oblanceolate, somewhat fleshy, channelled, 6 in. long, not narrowed into a petiole: peduncle 1-fld., 3 in. long, drooping; fl. triangular, 2 x 3 in., with tails 3 in. long, hairy inside, brown-yellow and purple-spotted; petals yellow, with red spots, pouch-like, serrate. Colombia. I.H. 20:117, 118 (as *M. Chimæra*).—Odd.

43. **Chimæ̀ra,** Reichb. f. Fig. 2332. Tufted: lvs. oblanceolate-obtuse, 1 ft. long and 1½ in. wide: peduncle wiry, erect, lateral or pendent, several-fld., mostly shorter than the lvs.; fls. opening in succession; calyx-lobes ovate, yellowish, much spotted with deep crimson-purple, tapering into slender tails from 3–11 in. long, purple-brown; petals white, marked with crimson; labellum saccate, white, yellow or pinkish, very variable. Colombia. R.H. 1881:130. G.C. II. 3:41. C.O. 5.—One of the most fantastic of orchids, and the type of a most interesting group.



2332. Masdevallia Chimæra. (×½)

Var. **Roézlii,** Hort. (*M. Roézlii*, Reichb. f.). No long hairs on the calyx-lobes, the lobes very dark-colored, with short warts; labellum pink, not yellow. Color the darkest of the section. Often regarded as a good species. Sub-var. **rùbra.** Spots on calyx-lobe brown-crimson.

Var. **Wállisii,** Hort. (*M. Wállisii*, Reichb. f.) Calyx-lobes with hispid pubescence, yellowish, spotted with brown-purple; labellum white, yellow within.

Var. **Winniàna,** Hort. (*M. Winniàna*, Reichb. f.). Calyx-lobes elongated, densely black-spotted. In part distinguished from var. *Roezlii* by its longer tails.

Var. **Backhousiàna,** Hort. (*M. Backhousiàna*, Reichb. f.). Lvs. narrower than in the type: fls. large; calyx-lobes more round, paler, not so thickly spotted; tails short; labellum nearly white.—Perhaps a distinct species.

44. **Chéstertonii,** Reichb. f. Tufted: lvs. oblong or oblong-spatulate, 5 in. long and nearly or quite 1 in. wide, somewhat longer than the pendent, much-bracted, 1-fld. peduncles: fls. 2½ in. across, greenish yellow, spotted and streaked with purple, and bearing 3 spreading, greenish, more or less hooked, flattened tails 1 in. long; petals yellow, very small. Colombia. B.M. 6977.—Odd and distinct.

SECTION V.

45. **triaristélla,** Reichb. f. Lvs. about 2 in. long, in very crowded tufts: peduncles longer than the lvs., very slender, erect, wiry: dorsal lobe of calyx ovate, hooded; tail yellow; lateral lobes coloring throughout their length, linear, united, at length diverging into short yellow tails; petals yellow, with a red midline. Summer. Costa Rica.—One of the smallest of orchids.

The following have been offered in Amer., but most of them are imperfectly known. *M. cheiróphora.*—*M. Chélsonii*=M. amabilis ×M. Veitchiana.—*M. gibberòsa*=Scaphosepalum.—*M. Héndersoni.*—*M. punctàta*=Scaphosepalum.—*M. trificàta.*

M. Alcéste=M. Veitchiana × M. Asmodia.—*M. Armínii*, Reichb. f. Fls. with whitish tube, the free portion of sepals crimson-purple, the lateral with filiform yellowish tails 1–2 in. long. Colombia. J.H. III. 50:313; 61:577.—*M. burfordiénsis*, O'Brien. Fls. white, profusely dotted with claret-color; petals white, with purple lobes; lip purple.—*M. deórsum*, Rolfe. Fls. yellow, blotched bright red; dorsal sepal reflexed, contracted suddenly into a tail 2–3 in. long; lateral sepals gradually narrowed into shorter tails. Colombia. B.M. 7766. G.C. III. 28:395.—*M. Ortgiesiàna*, Hort. Scape 1-fld.; fls. pale greenish white.—*M. peruviàna*, Rolfe. Petals white, tinged with lilac; sepals light brown. Peru.—*M. Pourbaìxii*, Hort.=M. Veitchiana × M. Shuttleworthii. Fls. vermilion, flushed with orange-yellow, and marked with numerous brownish red dots. G.M. 47:373. Lind. 9:387.—*M. Schroederiàna*, Hort. Sepals abruptly contracted into yellow tails, the dorsal arched, the lateral much recurved, thickly 3-nerved, bullate, white marked with red. Peru (?). B.M. 7859.—*M. Tondùzii*, Woolward. Peduncle slender, 1-fld.; sepals connate at base, whitish citron-colored inside, elongated into slender yellow tails. Costa Rica.—*M. venòsa*, Rolfe. Perianth straw-yellow, densely spotted with dull purple; lip dull red-purple. Colombia.—*M. Xípheres*, Reichb. f. Allied to M. muscosa: fls. small, purple, on tall slender sts. Colombia.

HEINRICH HASSELBRING.
GEORGE V. NASH.†

MASSÁNGEA (named for a Belgian horticulturist, M. Massange de Louvrex). *Bromeliàceæ.* A disputed genus; by Bentham & Hooker included in Caraguata, and by Mez combined with Guzmania. The single species admitted by Wittmack in Engler & Prantl, *M. musàica*, Morr., becomes *Guzmània musàica* (*Tillándsia musàica*, Lind. & André. *T. mosàica.* Hort. *Vrièsia musàica*, Hort.), by the Mezian disposition (see Vol. III, p. 1419). It is a good warmhouse subject.

MASSÒNIA (Francis Masson, 1741–1805, collector in S. Afr.). *Liliàceæ.* South African bulbous plants, of more than 30 species, allied to Allium; rarely grown as pot-plants in the greenhouse. Plants with 2 or 3 very broad opposite lvs., and a very short scape so that the usually white or greenish fls. are borne in a sessile or nearly sessile globose head at the surface of the ground surrounded by several membranaceous bracts: perianth with a cylindrical tube and narrow spreading or reflexed nearly equal segms.; stamens 6, inserted at the throat, the filaments more or less united at the base; ovary 3-celled and many-ovuled, becoming a membranaceous 3-valved caps. *M. pustulàta*, Jacq., has an ovoid bulb, 1 in. diam., ribbed tuberculate broad-oblong lvs., and greenish fls. in the cup of pustulate foliage; perianth-tube cylindrical, the segms. narrow and spreading; stamens long and upstanding. B.M. 642. G.C. III. 39:44.—An odd plant, requiring warm greenhouse conditions.

L. H. B.

MATRICÀRIA (*mater*, mother, from its use in diseases). *Compósitæ.* MATRICARY. WILD CHAMOMILE. Annual or perennial weedy herbs, often heavily scented.

From Chrysanthemum it differs mostly in the achenes, which are 3–5-ribbed on the interior face and ribless on the back; also in having a higher or more conical receptacle, and bracts in few rather than many series.—About 25 species in many parts of the world. The foliage is much cut or divided into thread-like divisions. The matricarias are border plants in cult., and others are intro. weeds. They are commonly confounded with species of Chrysanthemum and feverfew. The *M. exima plena* of the trade is a form of *Chrysanthemum Parthenium* (var. *tubulosum*). It is a good hardy annual, with white double heads, growing 2 ft. tall. Matricarias demand the care given to annual chrysanthemums. The three following are annuals or biennials.

inodòra, Linn. (*Chrysánthemum inodòrum*, Linn. *Pyrèthrum inodòrum*, Smith). Nearly or quite glabrous, branchy, diffuse annual, 1–2 ft. tall, from Eu.

and Asia: lvs. many, sessile, 2–3-pinnately divided or dissected: heads 1½ in. across, terminating the branches, with many acute white rays: achenes inversely pyramidal, with 3 conspicuous ribs. Not uncommon in fields eastward. Var. **pleníssima**, Hort. (var. *ligulòsa*, var. *múltiplex*, *M. grandiflòra*, Hort. not Fenzl), is a common garden plant with very double clear white large heads. It is floriferous, and the fls. are fine for cutting. G.C. II. 12:753.—It often persists and blooms the second year. Foliage little or not at all scented.

2333. Matricaria Chamomilla. (×¼)

parthenoìdes, Desf. (*M. capénsis*, Hort., not Linn. *Ánthemis parthenoìdes*, Bernh. *Chrysánthemum partheniòdes*, Voss). Annual, or biennial under cult., 2 ft. or less high, soft-hairy when young, but becoming smooth, bushy in growth: lvs. petiolate, twice divided, the ultimate segms. ovate and often 3-lobed: fl.-heads loosely corymbose, in the garden forms usually double, white.—A handsome plant, probably of Old World origin, useful for pots, and blooming till frost.

Chamomílla, Linn. (*Chamomílla officinàlis*, Koch). Wild Chamomile. Fig. 2333. Glabrous erect much-branched annual: lvs. 2–3-pinnate, with segms. short and very narrow-linear, giving the lf. a finely dissected appearance: heads rather large (nearly 1 in. across), on terminal peduncles, with 10–20 truncate white rays; bracts of involucre of about equal length, the edges scarious; receptacle without scales, elongating and hollow as anthesis advances: achene with 3–5 faint ribs and no border at top. Fields, Eu. and N. Asia; run wild in E. U. S.—Very similar in appearance to *Anthemis Cotula* (Fig. 219), but lacks the scales between the central florets and has a different odor. The name chamomile, or sometimes spelled camomile, is applied both in Matricaria and Anthemis. L. H. B.

MATRIMONY VINE: *Lycium.*

MATTEÙCCIA (from C. Matteucci, an Italian physicist). *Polypodiàceæ.* A small group of north temperate ferns with lvs. of two sorts, the sterile growing in crowns from erect rootstocks, and the fertile growing from the interior of the crown. Our species is known as the ostrich fern and is one of the most easily cult., as well as one of the handsomest of our native species. It multiplies rapidly by offsets sent out from the rootstock. Known also as an Onoclea or Struthiopteris. For cult., see p. 1217. For further botanical relations, see *Onoclea.*

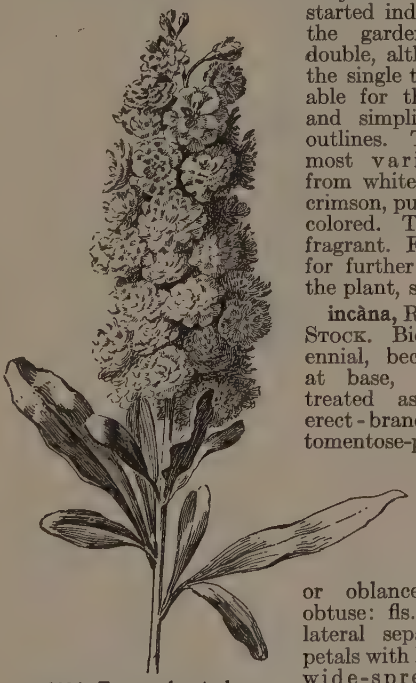
Struthiópteris, Todaro (*Struthiópteris germánica*, Willd. *Onoclèa Struthiópteris*, Hoffm.). Ostrich Fern. Lvs. (sterile) 2–6 ft. long, with the lowest pinnæ gradually reduced: fertile lvs. 1–2 ft. long, pinnate, with the margins of the pinnæ closely inrolled and covering the sori. Eu. and N. E. N. Amer.—Willdenow regarded the American species as distinct, but by most botanists it is considered identical with the European species.

L. M. Underwood.

MATTHÌOLA (Peter Andrew Matthioli, 1500–1577, Italian physician and writer on plants). Sometimes (and originally) spelled *Mathiola. Cruciferæ.* Stock. Gilliflower, when used at the present day, means Matthiola or sometimes Cheiranthus; formerly it designated *Dianthus Caryophyllus.* Familiar flower-garden and florists' subjects.

From Cheiranthus, the wallflower, this genus differs in its winged seeds, which are as broad as the partition, the stigma-lobes erect or connivent and often thickened on the outside, the silique not 4-sided (terete or compressed). Of Matthiolas there are probably 50 species, widely distributed in the Old World and Austral., 2 in S. Afr. They are herbs or subshrubs, tomentose, with oblong or linear-entire or sinuate lvs., and large, mostly purple fls. in terminal racemes or spikes.

The true stocks (Fig. 2334) are of this genus. The Virginian stocks are diffuse small-flowered annuals of the genus Malcomia (which see). Stocks are of two general types,—the autumn-blooming, Queen or Brompton stocks, and the summer-blooming, ten-weeks or intermediate stocks. By some persons these classes are made to represent two species, *M. incana* and *M. annua* respectively. It is probable, however, that they are garden forms of one polymorphous type. Even if distinct originally, it is not possible now to distinguish them by definite botanical characters.—Stocks are amongst the most common of all garden flowers. The two types cover the entire blooming season, particularly if the earlier ones are started indoors. Most of the garden forms are double, although some of the single types are desirable for the definiteness and simplicity of their outlines. The colors are most various, running from white through rose, crimson, purple and particolored. The flowers are fragrant. For culture and for further discussion of the plant, see *Stock.*



2334. Ten-weeks stock—Matthiola incana var. annua. (×⅓)

incàna, R. Br. Common Stock. Biennial or perennial, becoming woody at base, but usually treated as an annual: erect-branching, closely tomentose-pubescent, the sts. stiff and cylindrical: lvs. alternate, tapering into a petiole, long-oblong or oblanceolate, entire, obtuse: fls. with saccate lateral sepals and large petals with long claws and wide-spreading limb, borne on elongating stalks in an open, terminal erect raceme: siliques becoming 3–4 in. long, erect. Medit. region; also Isle of Wight.—*M. glabràta*, DC., is a glabrous form.

Var. **ánnua,** Voss (*M. ánnua*, Sweet. *M. græca*, Sweet). TEN-WEEKS, or INTERMEDIATE STOCKS. Fig. 2334. Annual, less woody, blooming earlier.—A shining-lvd. variety is known. Var. **autumnàlis,** Voss. Autumn-blooming or Brompton stocks.

bicórnis, DC. Half-shrubby, straggling annual or biennial: fls. smaller than those of *M. incana*, purplish or lilac, fragrant by night, closing by day: pod terete, long, 2-horned: lvs. pinnatifid, or the uppermost entire. Greece, Asia Minor. Gn.M. 3:226.

M. coronopifòlia, DC. Perennial, somewhat woody at base, hoary-pubescent: lvs. linear-oblong, sinuate-lobed or somewhat pinnatifid: petals wavy, vinous purple. Sicily. B.M. 7750.—*M. maderénsis*, Lowe. Woody at base, spreading: lvs. long-lanceolate, acute, soft-tomentose, usually entire: fls. pale violet, or violet-purple, rarely white, fragrant. Madeira. Gt. 1:354.—*M. pedemontàna*, Hort. Apparently a form of M. varia: fls. light rosy purple: decorative for the rock-garden. G. C. III. 53:149.—*M. sinuàta* var. *oyénsis*, Rouy. & Fouc. (M. oyensis, Ménier), is figured in B. M. 7703, where it is said that "the name oyensis has been corrupted in gardens to ohiensis and chinensis." The plant is from the Ile d'Yeu (Insula Oya, whence the name) on the coast of France. It is an annual or biennial, with sinuate-toothed lvs., hairy, and with large white fragrant fls. Not known to be in cult. in this country.—*M. vària*, DC., Italy and Greece, a variable species, some forms of which may appear in cult. Perennial: lvs. linear, obtuse, entire, canescent: petals oval, undulate, purplish.

L. H. B.

MAURÁNDIA (after Maurandy, professor of botany at Cartagena, Spain). Also written *Maurandya*. *Scrophulariàceæ*. Perennial herbs, grown for the showy flowers and for the climbing habit of some of them.

Botanically, this genus is near to the snapdragon, though the throat of the fl. is not closed. The plant known to the trade chiefly as *Maurandia antirrhiniflora* is now referred to Antirrhinum. (See *Antirrhinum*, Vol. I, p. 305, where this plant is described and figured.) It is a climber and requires the cult. of maurandia. Maurandias climb by the twisting of the lf.- and fl.-stalks. They are glabrous or pubescent: lvs. alternate, or the lower ones opposite, triangular or halberd-shaped, angular-lobed or coarsely toothed: calyx 5-parted; segms. narrow or broad; corolla-tube scarcely bulged or gibbous at the base, essentially funnelform, with bearded lines instead of a palate; posterior lip 2-cut; anterior lip variously parted; stamens 4, didynamous: fr. a caps. with winged or wingless seeds.—About 6 or 8 species of Mexican and Arizonian plants, mostly climbers, with showy, irregular trumpet-shaped fls., white, rose, purple and blue, the throat usually white or light-colored, somewhat 2-lipped.

2335. Maurandia Lophospermum. (×¼)

Perhaps the commonest cultivated species is *M. Barclaiana*, which is procurable in a greater range of colors than the others. Maurandias are desirable vines for winter-flowering in cool greenhouses, but since they bloom the first year from seed, they are almost wholly grown for summer bloom outdoors and treated like tender annuals. They have a slender habit and grow about 10 feet in a season. In autumn the vines may be taken up and removed into the house if desired. In some of the recently introduced species the habit is prostrate or pendulous rather than climbing.

Maurandias can be increased either by seed or cuttings. When grown from seed, the pans or flats should be given a liberal amount of crocks, and this covered with some coarse material. For a compost use four parts new loam, two parts leaf-mold, one part sand, well mixed together. Fill the pans to about ½ inch from the top, firming the material. For covering the seeds, screen some of the compost and cover about three times the size of the seed. Water with a fine rose. Place the pans in a house with a night temperature of 60°. Cover with glass and keep shaded until they start to germinate. When large enough to handle, pot off into 2- or 2½-inch pots, using the same compost, adding about one-fourth part of well-decayed cow-manure. When intended for the conservatory, they should be shifted along until they are in 6- or 7-inch pots. For these larger shifts use a compost of four parts of fibrous soil, one part each of cow-manure and leaf-mold, and a small amount of bone-meal. Maurandias can also be grown from cuttings taken any time after the middle of January, using an intermediate propagating-bed and grown on as above stated. For their general culture, they like a night temperature of 55° to 60° with a rise of 10° to 15° with sun heat. Water should be given when they show a dryness at the roots. On bright days they should receive a good syringing to keep the foliage clean and healthy. When they have filled the soil with roots, liquid manure given about once a week will keep them vigorous. Train the shoots and give them additional room as they may require. Maurandias are largely grown for baskets, vases and the like. The most troublesome insects are red-spider and aphids. Syringe to keep the former in check and fumigate frequently for aphids. (J. J. M. Farrell.)

A. *Plant climbing.*

B. *Seeds tubercled, wingless: calyx-segms. narrow: lvs. hastate, not serrate.* (*Subgenus Eumaurandia.*)

C. *Calyx distinctly glandular-pilose; segms. long-attenuate*

Barclaiàna, Lindl. Usually, but not originally, written *Barclayana*. Climber, somewhat woody: lvs. angular, cordate, acuminate, the petioles longer than the blades and twining: fls. about 3 in. long, downy outside, deep purple, personate; upper lip of corolla with 2 transverse rounded lobes, the lower lip with 3 roundish ovate lobes. Mex. B.R. 1108. L.B.C. 14:1381. V. 5:353.—The following trade names advertised like species-names are presumably all color-varieties of this species: *M. alba*, *M. albiflora*, *M. Emeryana*, *M. rosea*, *M. Luceyana*, *M. purpurea grandiflora*, *M. varius*. The last is a trade name for mixed varieties.

CC. *Calyx glabrous, shorter.*

scándens, Pers. (*Ustèria scándens*, Cav. *M. semperflòrens*, Ort.). Shrubby below: lvs. halberd-shaped, long-acuminate, the margins not toothed: fls lavender-colored; throat white. Mex. B.M. 460.—Cult. in S. Calif.

BB. *Seeds with a lacerated or irregular wing: calyx-segms. leafy and broad: lvs. triangular-ovate, serrate.*

C. *Corolla-lobes obtuse or even notched.*

erubéscens, Gray (*Lophospérmum erubéscens*, Don). Woody climber, glandular-hairy: lvs. somewhat triangular in outline, serrate; petiole as well as peduncle twining: fls. 3 in. long, rosy pink. Mex. B.M. 3037, 3038 (as *L. scandens*). B.R. 1381. G.C. II. 20:501.—Cult. in S. Calif.

cc. *Corolla-lobes more acute.*

Lophospérmum, Bailey, nom. nov. (*M. scándens,* Gray, not Pers. *Lophospérmum scándens,* D. Don). Fig. 2335. Perhaps a botanical variety of the preceding. Branches long and slender, glandular-pubescent: lvs. opposite below and alternate above, cordate, subacute, unequally toothed, the petiole twining: corolla twice as long as calyx, rose-purple, obscurely dotted outside, the tube white; lobes triangular ovate, acute or the lower ones nearly obtuse. B.M. 3650.—A handsome plant. A hybrid with the preceding is shown in B. 5: 242. The plants passing in gardens as *M. scandens* need to be worked over botanically.

AA. *Plant not climbing, although with pendulous or lopping growth.*

Púrpusii, Brandegee. Ascending, pendulous or prostrate, 12–16 in., leafy, with tuberous rootstock: lvs. long-stalked, more or less triangular-ovate: fls. axillary, long-peduncled, purple-carmine, beautiful. S. W. Mex. —A showy tender perennial, blooming the first year from seed, of bushy growth; tubers may be stored in winter. Differs from *M. erubescens* in being more glabrous and bearing smaller fls.; lvs. often entire-margined.

M. Conzáttii, Hort., that has been listed in S. Calif.=M. scandens, Pers.

L. H. B.†

MAURÍTIA (after Prince Moritz, of Nassau, 1567–1665, patron of Piso and Marcgraf; by his aid a Natural History of Brazil was published). *Palmàceæ,* tribe *Corỳphinæ.* Very graceful fan palms, very little grown in America except in botanic gardens.

Stems very slender, obscurely ringed, almost spineless: lvs. pinnately flabelliform, semi-circular, orbicular or wedge-shaped, the lobes lanceolate, acuminate; rachis long or short; petiole cylindrical: ovary perfectly 3-celled.—There are 6 or 7 species, all Trop. American. Mauritia must be grown in rich soil in a very hot moist house with a day temperature of 80–85°. The pots of small plants are often partly submerged in water. G.C. II. 26:491.

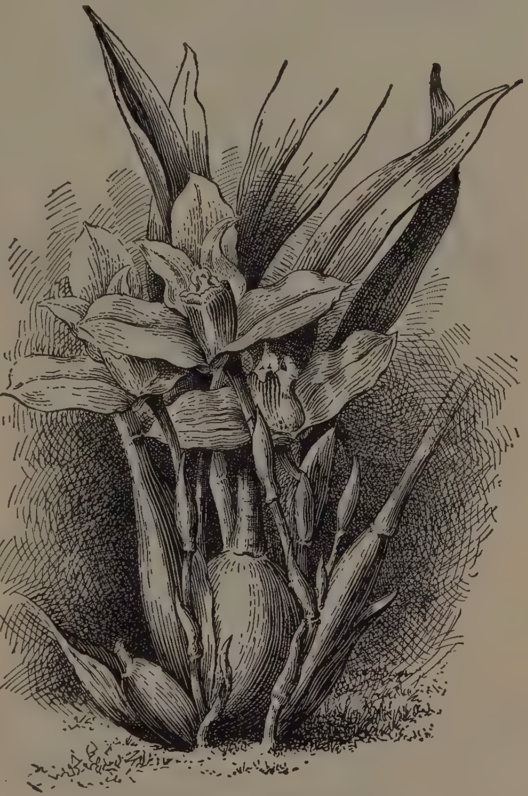
flexuòsa, Linn. f. Moriche Palm. Ita Palm. Sts. without stolons, in nature often 90 ft. tall: lvs. 20–30, erect-spreading, 9–16 ft. long; blade 2½–4 ft. long, yellowish beneath; lobes ⅔–1½ in. wide; petiole stout, rigid, semi-cylindrical, equaling the blade: fr. nearly 2 in. long, depressed-globose; seed 1⅓ in. long. Trop. Brazil.—Offered in 1889 by Reasoner Bros. In the Amazon delta this palm grows to 150 ft. or more in height, with a trunk often 30 in. diam. at base. "The fr. is spherical, the size of a small apple, and covered with rather small, smooth, brown, reticulated scales, beneath which is a thin coating of pulp. A spadix loaded with fr. is of immense weight, often more than two men could carry between them."—Wallace, "Palms of the Amazon." It forms extensive forests, and provides material for subsistence and arts of the Indians.

N. Taylor.†

MAUROCÈNIA (J. F. Mauroceni, Venetian senator and horticulturist). *Celastràceæ.* One shrub in S. Afr., producing a drupe as large as a cherry and called "Hottentot cherry," *M. frangulària,* Mill. (*M. capénsis,* Sond. *Cassìne Maurocènia,* Linn.). Glabrous, 4–6 ft., with 4-angled twigs: lvs. coriaceous, opposite, entire, suborbicular to elliptical or obovate: fls. small, greenish to white, in axillary clusters; calyx very small, 5-parted; petals 5, exceeding the calyx; disk ring-like; stamens 5, exceeding the petals: drupe somewhat juicy, with a hard stone. Cape of Good Hope region.—Apparently not in the trade.

MAXILLÀRIA (Latin, *maxilla,* jaw; referring to the mentum). *Orchidàceæ.* Mostly pseudobulbous epiphytic orchids, resembling lycaste in general appearance.

Rhizomes short or long, creeping or erect, and clothed with distichous lvs.: pseudobulbs clustered or scattered on the rhizome, 1–2-lvd. or densely distichophyllous at the apex of the rhizome: lvs. leathery or subfleshy, plicate or plane and keeled, distichous: sepals subequal, free from each other but united with the foot of the column and forming a projecting mentum; petals similar or smaller; labellum 3-lobed, movably articulated to the foot of the column; lateral lobes erect; middle lobe with longitudinal callosities; the scape arises apparently from the base of the pseudobulb, on the very young leafy axis, but lower down than the corresponding new growth; pollinia 4, seated on a broad, scale-like stipe.—Over 100 species, dispersed at various altitudes in Mex., Brazil and the W. Indies. About 15 species are offered by dealers in Amer. Many of these have small fls. and are of value only in collections. They are, however, easily grown, and blossom profusely. Among those given below, the large white-fld. *M. grandiflora* and *M. venusta,* and the white and purple *M. Sanderiana* are probably the best species. The distichous arrangement of the lvs. distinguishes this genus from Lycaste. For *M. Harrisoniæ* and *M. tetragona,* see *Lycaste.*



2336. Maxillaria grandiflòra. (× nearly ½)

Maxillarias are of easy culture, and can be grown under various methods of treatment with fair success. The best compost consists of clean peat fiber taken from the several species of Osmunda, and live sphagnum, both chopped rather fine and well mixed together. After the receptacle is half filled with clean drainage and the plant properly placed, the compost should be pressed firmly in around the roots, interspersing it with nodules of charcoal. In their native habitats, many of the fine-rooted species grow on rocks and trees with very little compost attached. The base of the pseudobulbs or rhizome should rest on a convex surface raised a little above the rim of the pot when finished. Maxillarias delight in a cool, moist, shaded location at all seasons; the winter temperature should not exceed 58° F. by night and not over 60° or 65° by day. During summer they must be grown as cool as possible with ventilation at all seasons when admissible, especially in wet heavy weather. Water should be given in abundance while the plants are growing and not too sparingly when at rest, as the plants are subject to spot if kept too dry. Weak liquid cow-manure is beneficial occasionally during root-action.—Maxillaria has two recognized horticultural groups or sections; viz., caulescent and stemless. The caulescent section embraces *M. tenuifolia*, *M. variabilis* and kindred species, having scandent rhizomes and often obscure flowers. These should all be grown under pot culture and afforded supports to climb on, such as small cylinders or rafts of open woodwork with a little compost worked in the openings, or osmunda rhizomes supported obliquely in the pots to which the plants can attach themselves as they grow upward, and thus be supplied with moisture for the young roots. To the stemless section belong those with clustered pseudobulbs, as *M. grandiflora*, *M. luteo-alba*, *M. picta*, *M. Sanderiana* and *M. venusta*. Some of the these have very showy flowers. Nearly all do best under pot culture. *M. Sanderiana* and others are exceptions, however, and grow best under basket culture, not too much compost and an airy position. Demand for maxillarias not being great, the market usually relies on new importations, but stock may also be increased by division between the pseudobulbs as the plants start new action. (Robt. M. Grey.)

  12. **variabilis**
  13. **tenuifolia**

1. **venùsta,** Lind. & Reichb. f. Pseudobulbs oblong, compressed, 2-lvd.: lvs. oblong-lanceolate, acuminate, plane, 1 ft. long: scapes 6 in. long, bearing a single glistening white fl. 6 in. across; sepals and petals long-lanceolate, acuminate, spreading; the lateral sepals wider, labellum much smaller; middle lobe triangular recurved, obtuse, yellow; lateral lobes very obtuse, bordered with red; disk with a rounded, hairy callus. Winter and spring. Colombia. B.M. 5296. G.C. III. 12:367 (abnormal).—A large-fld., showy species.

2. **grandiflòra,** Lindl. Fig. 2336. Pseudobulbs clustered, oval: lvs. erect, plane, keeled, ovate-oblong, 1 ft. long: scapes erect, 3–6 in. long, bearing solitary, large white fls. 3–4 in. across; sepals broadly ovate to oblong; petals ovate-acute, suberect, with recurved tips; labellum saccate, white, much-striped with purple on the sides; middle lobe tongue-like, white, bordered with yellow. Aug. Peru and Colombia. I.H. 17:14.—A very showy and beautiful plant.

3. **Léhmannii,** Reichb. f. Fl.-stalks nearly 1 ft. long, bearing white fls. nearly as large as those of *Lycaste Skinneri;* side lobes of the labellum light ocher outside and light reddish brown with chestnut veins inside; middle lobe triangular, wavy, sulfur-color. Ecuador.—Resembles *M. grandiflora,* but distinguished by the character of the lip.

4. **Sanderiàna,** Reichb. f. Fig. 2337. Pseudobulbs orbicular to broadly oblong, 1–1½ in. long: lvs. few, 6–10 in. long, oblanceolate, plane, keeled: scapes 2–3 in. long; fls. 4 in. across, pure white, with the bases of the segms. purplish red, broken upward into blotches; dorsal sepals oblong-obtuse, concave; lateral sepals triangular-ovate, forming a broad mentum at base; lateral lobes of the labellum almost obsolete, middle lobe rounded, crisp, bright yellow, throat dark purple, with a club-shaped callus. Ecuador. B.M. 7518. R.H. 1894:526. J.H. III. 26:495. G.M. 52:414. O. 1909; 26. A.G. 9:13 (adapted in Fig. 2337).—The finest known species.

5. **Líndeniæ,** Hort. (*M. Lindeniàna,* Rich. & Gal.?). Plants resembling *M. Sanderiana,* but the fls. larger and more open: sepals triangular-lanceolate, spreading, 3 in. long, pure white; petals shorter and wider, erect, white; labellum fleshy, obovate, somewhat crisp, recurved, pale yellow, with 5–6 red lines on the lateral lobes. S.H. 1:219.

6. **pícta,** Hook. (*M. fuscàta,* Klotzsch). Pseudobulbs 1½ in. high, ovate, furrowed, bearing 1–2 plane, strap-shaped lvs. 1 ft. long: scape 5–6 in. high; fls. nodding; sepals and petals oblong-linear, acute, incurved, deep

orange spotted with purple within, white with deep purple spots outside; labellum oblong, whitish, spotted; side lobes small, rounded; midlobe recurved, apiculate. Winter. Brazil, Colombia. B.M. 3154. B.R. 1802.—Handsome.

7. **rufèscens,** Lindl. (*M. fuscàta*, Reichb. f.). Pseudobulbs ovate, subtetragonal, 1-lvd.: lvs. lanceolate, acuminate: scape short, with 1 small fl.; sepals and petals oblong-obtuse, yellow-tinged and spotted with reddish orange; side lobes of labellum small, sharp; middle lobe elongate, sub-quadrate, emarginate; all yellow, spotted with crimson. Trinidad. B.R. 1848.—Not valuable.

8. **elegántula,** Rolfe. The bases of the segms. white, the outer halves pale yellow, marked with chocolate-color. Nov. G.C. III. 22:420.—From the illustration, the sepals are ovate-lanceolate, wavy and recurved, the lower pair broader; petals smaller, pointing forward, concave, wavy, with reflexed tips: lvs. lanceolate-acute.

9. **lùteo-álba,** Lindl. Pseudobulbs long-ovate, 1-lvd., 2½ in. high: lvs. broad, obtuse, narrowed at the base, 1 ft. long: scapes 6 in. long; sepals 3 in. long, ½in. wide, tawny yellow fading to white at the base, brown on the back, the lower pair drooping; petals erect, pointing forward, one-half as long, white to brown and yellow above; side lobes of the labellum yellow with purple streaks; middle lobe recurved, hairy, yellow, with white margins. Colombia. G.C. III. 43:165.—A robust species, which soon fills large-sized pans, making very ornamental plants.

10. **striàta,** Rolfe. Scapes 6–8 in. long, bearing solitary fls. 4–5 in. across the sepals; dorsal sepals ovate-oblong; lateral sepals ovate-attenuate, forming a broad mentum at the base, often twisted and recurved; petals narrower, wavy; both sepals and petals are yellow, striped with red-brown; lobes of the labellum crenate-wavy, white with purple veins, the lateral ones recurved. Aug. Peru. G.C. III. 20:631. G.M. 41:705.

11. **Houtteàna,** Reichb. f. Fig. 2338. Rhizome erect or ascending, clothed with brown sheaths: pseudobulbs 2–2½ in. long, linear-oblong, compressed: lvs. solitary, 6 in. long, linear, obtuse, keeled: scape 1½–2 in. long; fls. nearly 2 in. across; sepals ovate-lanceolate, dirty yellow outside, red-purple within, with a yellow margin and spotted below; petals smaller, colored like the sepals; labellum without lateral lobes, oblong-obtuse, yellow with red-brown spots, and an ill-defined callus on the base. April. Guatemala and Venezuela. B.M. 7533.—Fls. last about a month in the coolhouse.

12. **variábilis,** Batem. (*M. angustifòlia*, Hook.). Pseudobulbs oval, compressed: lvs. solitary, plane, linear-oblong, obtuse or emarginate: fls. solitary, small, deep purple; sepals linear-oblong, acute, the lateral ones produced at the base; petals subsimilar; labellum oblong, retuse, fleshy, membranous at the base; disk with a small callus. Midwinter. Mex. B.M. 3614 (as *M. Henchmanni*).—A small plant, of interest only to collectors.

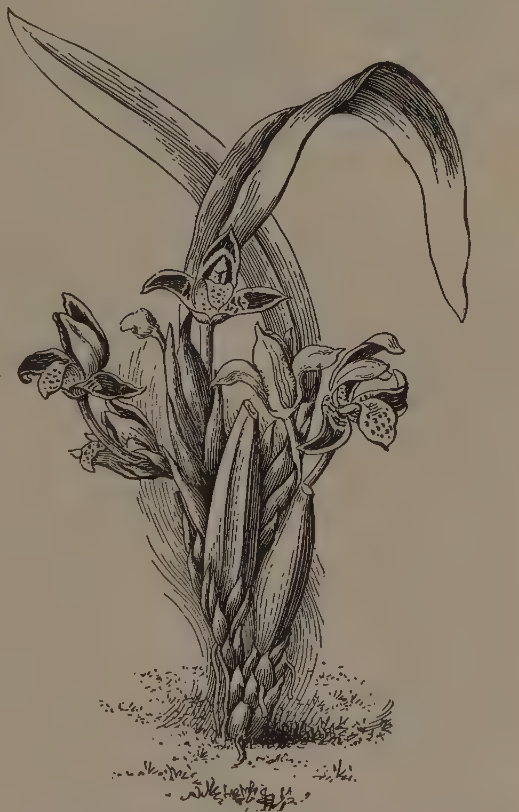
13. **tenuifòlia,** Lindl. Rhizomes erect, bearing ovate-compressed pseudobulbs at irregular intervals: lvs. linear-lanceolate, acute, recurved, grass-like, plane: fls small, spotted and shaded with purple and yellow; sepals ovate-lanceolate, margins revolute, reflexed; petals ovate, acute, erect; labellum oblong, reflexed, with an entire, oblong callus. Spring. Mex. B.R. 25:8.—Not valuable.

M. abbreviàta, Reichb. f. Fls. solitary, on long bracted peduncles, copper-colored. O. 1911:106.—*M. Binòtii*, De Wild. Peduncles solitary or geminate: fls. yellow; lip densely purple-dotted toward the middle. Brazil.—*M. dichròma*, Rolfe. Related to M. venusta, but the petals suffused on the lower half with light pinkish purple, the lip margined, with same color; sepals white.—*M. Fletcheriàna*, Rolfe. A new species intermediate between M. Sanderiana and M. grandiflora in the form and size of fl.: fls. large, cream-white, with purple lines; lip yellow. Peru.—*M. fractifléxa*, Reichb. f. Sepals yellow, bronzy-tinged, twisted; petals cream-colored, twisted and coiled, warty-margined; lip white, purple-marked. Ecuador. G.C. III. 31:359.—*M. funèrea*, Lindl. "Fls. with broad purple-brown sepals and petals, and a darker shining lip, having a broad crest." Brazil.—*M. Fuerstenbergiàna*, Schlecht. Fls. large, snow-white, front part of sepals orange-yellow; middle lobe of lip bordered with red. Peru. O. 1912:116, desc.—*M. Henniseàna*, Schlecht. Fls. yellowish white, fragrant. Colombia. O. 1912:117, desc.—*M. incarnàta*, offered by Lager & Hurrell, a trade name only.—*M. iridifòlia*, Reichb. f. Lvs. distichous, equitant, lanceolate, acuminate; sepals triangular; lip ligulate-pandurate. Colombia.—*M. Johniàna*, Kränzl. Scape 1-fld.; fls. widely expanded, white; sepals and petals deep lilac in upper half; lip yellowish, edged with lilac. Peru.—*M. phœnicánthera*, Rodrig. Fls. white or pale yellow, dotted with purple. Brazil.—*M. púlla*, Lind. & Reichb. f. Plant small: fls. straw-yellow, striped with red-brown. Colombia.—*M. pusílla*, Rolfe. Scapes solitary, short; sepals and petals brownish green; lip dark purple, shiny.—*M. scúrrilis*, Rolfe. Sepals and petals elongated, narrow, curved, dark-spotted, 5–6 in. long. G.C. III. 28:65; 32:243, 245.

Heinrich Hasselbring.
George V. Nash.†

MAXIMILIÀNA (after Maximilian Joseph, first king of Bavaria, 1756–1825, not Prince Maximilian Alexander Philipp, as said by some). *Palmàceæ*, tribe *Attáleæ*. Tall pinnate-leaved palms, spineless, with ringed trunks. Known also as *Englerophœnix;* see *Maximilianea*, below.

Leaves with linear pinnæ in groups, the midveins and transverse nerves prominent; rachis bifacial, strongly compressed; petiole plano-convex. This genus is distinguished from Attalea as follows: petals of the male fls. minute, much shorter than the 6 exserted stamens: fr. 1-seeded: pinnæ in groups instead of equidistant. From Cocos and Scheelia it differs in the above floral characters and in the plano-convex instead of concavo-convex petioles. Fr. yellow or brown, ovoid, with fibrous or fleshy pericarp and bony endocarp, the latter 3-pored at the base, acuminate at the apex.—Species 3, St. Kitts, Trinidad and S. Amer. For cult., see *Palms*.



2338. Maxillaria Houtteana. (×⅓)

A. *Pinnæ verticillate at least on some part of the rachis.*

Marìpa, Drude (*Attalèa Marìpa,* Mart. *Englerophœnix Marìpa,* Kuntze). St. thick, very tall: lvs. 15 ft. long; segms. sword-shaped, acute, divaricate, the lower 3 ft. long, 2 in. wide, gradually diminishing upward: spadix and spathe very woody, the fls. very large for a palm, frequently ¾in. long. Brazil.

2339. Maximiliana regia.

AA. *Pinnæ in opposite clusters.*

règia, Mart. (*Attalèa amygdálina,* HBK. *Englerophœnix règia,* Kuntze). Fig. 2339. St. 15–20 ft. high, 12–16 in. thick at the base, 3 times as thick above because of the persistent petiole bases: lvs. 15 ft. long; segms. more slender, papery, disposed in opposite clusters, the upper as broad as the lower: spadix about 12 in. long, the stalk stout: fls. showy and the fibrous fr. about 2 in. long. Brazil. G.C. III. 1: suppl. Feb. 12.

N. Taylor.†

MAXIMILIÀNEA. *Bixàceæ.* An unfortunate confusion has arisen in the application of this name. As *Maximiliana* (1824), it is accepted for a genus of palms (see above); under the slight variation *Maximilianea* (1819), it is adopted by Warburg in Engler & Prantl, III. 6:312, for the bixaceous genus usually known as Cochlospermum (Kunth, 1822). Different ways out of the difficulty have been suggested. One is to supplant the palm Maximiliana with a new name (Englerophœnix), and to hold Maximilianea in place of Cochlospermum. Another is to allow the palm name to stand, being well established, and for the bixaceous plants to fall back on Cochlospermum; this conforms better to usage and is the more practicable. (See Engler & Prantl, Nachtr. I. 56; O. Kuntze, Rev. Gen. Pl. I. 44.) Still another is to allow both the Maximilian genera to stand, seeing that they are differently spelled; but they are so near alike that conflict would result. Another alternative is to revise the name Wittelsbachia (1824) for Cochlospermum, seeing that the latter is antedated by the Cochlospermum of Lagasca (1818); but this way of escape need not concern us here. Cochlospermum is retained in the "nomina conservanda" of the Vienna Code. Recent authorities make the genus the type of the family *Cochlospermaceæ.*

Maximilianea, or Cochlospermum, comprises about 12–15 trees, shrubs and subshrubs in tropical and subtropical regions of both hemispheres, little known as horticultural subjects: lvs. alternate, digitate or palmately parted: fls. large and showy, yellow, pedicelled, in fascicles, racemes or panicles from the upper axils or terminal, perfect; sepals 5, unequal, imbricate; petals 5, large; stamens very many, free, with long anthers; ovary 1-celled, with 3–5 placentæ, the style undivided and slender: caps. 3–5-valved, with numerous seeds.

M. hibiscòdes, Kuntze, **Cochlospérmum hibiscoìdes,** HBK. (*C. serratifòlium,* DC.). Shrub: lvs. palmatifid into 7 long-acuminate sharply serrate lobes lighter colored on the under side, the basal lobes small: fls. very large and showy, yellow, with oval or obovate deeply notched petals; the numerous stamens incurved into a ball-like body in the center. S. Mex. to Colombia, W. Indies.—Offered in S. Calif. Hemsley's plate (Biol. Cent.-Amer.) shows a brilliant fl. 6 in. across.

M. Gossýpium, Kuntze, or **Cochlospérmum Gossýpium,** DC. (*Bómbax Gossýpium,* Linn.), is apparently not in the trade, although recorded in horticultural literature. India: a small unarmed tree: lvs. palmately 3–5-lobed, with slender petiole, acute lobes, tomentose beneath: fls. 4–5 in. diam., golden yellow, in few-fld. terminal panicles; petals obovate, notched: caps. 2–3 in. long.

L. H. B.

MAXIMOWÍCZIA: *Schizandra.*

MAY APPLE: *Podophyllum;* also *Passiflora.*

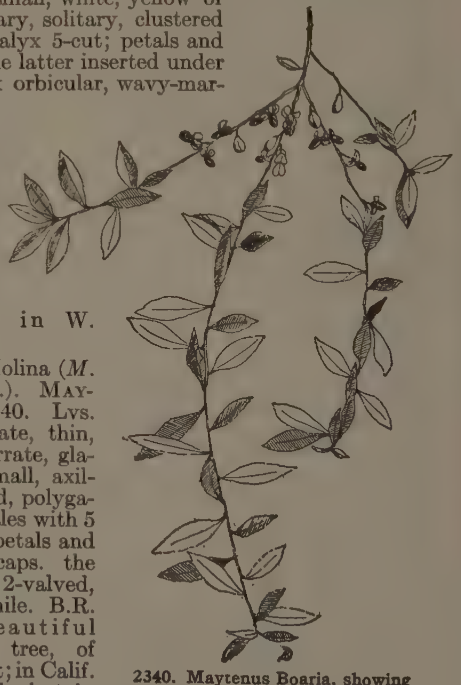
MAYBERRY, JAPANESE GOLDEN: *Rubus palmatus.*

MAYFLOWER of English literature is the same as the hawthorn, *Cratægus Oxyacantha;* of New England is *Epigæa repens;* of the more western states, *Hepatica.*

MAYTÈNUS (from a Chilean name). *Celastràceæ.* Trees and shrubs in tropical and temperate America, one of which is cultivated.

Botanically they are near the common bittersweet, *Celastrus scandens.* Aside from habit, Maytenus differs from Celastrus in having the ovary confluent with the disk instead of free, and the cells are mostly 1-ovuled instead of 2-ovuled. It consists of evergreen, unarmed plants: lvs. alternate, often 2-ranked, stalked, leathery, serrate: fls. small, white, yellow or reddish, axillary, solitary, clustered or cymose; calyx 5-cut; petals and stamens 5, the latter inserted under the disk; disk orbicular, wavy-margined; style none or columnar: caps. leathery, loculicidally 2–3-valved.—Species 70 or more, S. Amer., tropical and temperate, and in W. Indies.

Boària, Molina (*M. chilénsis,* DC.). Mayten. Fig. 2340. Lvs. ovate-lanceolate, thin, glandular-serrate, glabrous: fls. small, axillary, clustered, polygamous, the males with 5 calyx-teeth, petals and stamens: caps. the size of a pea, 2-valved, 2-seeded. Chile. B.R. 1702.—A beautiful evergreen tree, of graceful habit; in Calif. 15–25 ft. high, but in



2340. Maytenus Boaria, showing the dehiscing fruit.

Chile said to attain 100 ft.: branchlets pendulous: lvs. small: fls. minute, greenish, inconspicuous; aril scarlet. Perfectly hardy in Calif. as far north as San Francisco, and highly valued for ornamental planting; recommended as a street and avenue tree: timber extremely hard. Prop. readily from seeds, which are produced in abundance, or from suckers. J. Burtt Davy.

MAY-WEED: *Anthemis Cotula.*

MÀZUS (from the *teats* or tubercles in the mouth of the corolla). *Scrophulariàceæ.* A half-dozen low annuals or perennials, seldom grown in rock-gardens and similar places in mild climates. Allied to Mimulus, from which it differs in usually having the fls. in subsecund racemes rather than axillary or ordinarily racemed, trailing habit and technical floral characters: lvs. opposite or rosulate, or alternate above, variously toothed or cut: fls. small, bluish or white; corolla-tube short, the upper lip erect and 2-lobed, the throat with 2 projecting protuberances; stamens 4, didynamous; style slender, with 2-lamellate stigma.—Mostly prostrate, creeping or runner-bearing herbs in India, Malay Archipelago, China, Austral., New Zeal.

M. pumílio, R. Br. Small perennial, creeping underground and sending up short close-leafy branches: lvs. tufted, obovate-spatulate, obtuse, entire or somewhat sinuate-toothed: peduncles 1–6 fld., usually exceeding lvs., the fls. bluish or white with yellow center. Austral., New Zeal. Listed as an "alpine."—*M. radìcans*, Cheesem. (Mimulus radicans, Hook. f.). Very low, the erect leafy branches rising 1–3 in. from creeping or subterranean sts.: lvs. close, 2 in. or less long, obovate to linear-obovate, obtuse, entire or obscurely sinuate: fls. 1–3 on terminal peduncles, ½–¾in. long, white with yellow center, the tube much exceeding the calyx. New Zeal.—*M. réptans*, N.E. Br. Tufted perennial, 1–2 in. high, the sts. slender, prostrate and rooting at the nodes: lvs. opposite, lanceolate to elliptic, few-toothed: racemes 2–5-fld., erect; fls. purplish blue with lower lip blotched white, yellow and red-purple: plant somewhat resembling some of the small lobelias. Himalaya. B. M. 8554. G.C. III. 53:210 (as M. rugosus).—*M. rugòsus*, Lour. Annual, without runners: radical lvs. obovate-spatulate, crenate-dentate: peduncles many from the root, 2–10 in. long; fls. blue. India.

MEADOW BEAUTY: *Rhexia.* **M. Foxtail:** *Alopecurus pratensis* (a meadow grass). **M. Pink:** *Dianthus deltoides.* **M. Rue:** *Thalictrum.* **M. Saffron:** *Colchicum.* **M. Sweet:** *Filipendula.* **M. Tulip:** *Calochortus.*

MECONÓPSIS (Greek, *poppy-like*). *Papaveràceæ.* Poppy-like herbs, annual and perennial, useful as garden flower plants.

Simple or rarely much-branched plants with yellow juice, annual or biennial (monocarpic: seeding but once) or perennial, with showy large yellow, reddish or blue fls. in cymose racemes or panicles or borne singly: lvs. stalked when radical, short-stalked or sessile when cauline, entire, lobed, or dissected: sepals 2, usually deciduous; petals 4, varying to 5–10; stamens many; stigmas forming a globular mass or body on the several- to many-carpelled ovary: caps. oblong to clavate or even cylindrical, 1-celled with 4 or more projecting placentæ, opening by short teeth or valves at the summit.—Species 28 as defined by Fedde (Das Pflanzenreich, hft. 40. 1909), in the northern extra-tropical regions, mostly in Asia, 2 in W. N. Amer.; other species have been described subsequently. In 1906, Prain admitted 27 species (Ann. Bot. XX, pp. 323–365).

The species of Meconopsis have recently come into much prominence, mostly as herbaceous perennial subjects for borders and rock-gardens. Heretofore these plants have been known mostly by *M. cambrica* and *M. heterophylla*, but within ten or twelve years many attractive species have been introduced from the high elevations in the China-Thibet region. It is probable that the genus will have a great extension of popularity among gardeners. Hybrids already have appeared. Coming from high altitudes, they may be treated as hardy plants. They propagate readily from seed sown directly in the open in spring, or they may be started under glass and transplanted. The annual-biennial species may be carried as seedlings in pots the first summer and planted out in autumn if it is desired to bloom them the second year. They require partial shade. The Chinese and Himalayan species are essentially alpines, and it is probable that they would not withstand the American summers without very special treatment. Their availability here is yet to be determined.

A. *Sts. branching: st.-lvs. pinnate or pinnately parted*

B. *Fls. yellow.*

1. **cámbrica**, Vig. (*Papàver cámbricum*, Linn.). Welsh Poppy. Perennial, forming large tufts with thick roots: sts. slender, about 1 ft. high: lvs. long-stalked, pale green, slightly hairy, pinnate, dentate, with 5–7 segms. which are ovate or lanceolate and toothed or pinnately lobed: fls. rather large, long-peduncled, pale yellow: caps. oblong or ovate, glabrous, containing reniform-oval blackish seeds: fls. standing well above the mass of attractive foliage. Rocky woods and shady places. W. Eu. G.C. III. 19:671; 54:52. Var. **flòre-plèno**, Hort., is a double-fld. form. It is described as a very showy and worthy plant, with the very double yellow fls. striped scarlet. G.M. 46:373.

2. **chelidonifòlia**, Dur. & Franch. Perennial, rhizomatous, glaucous, 2 ft., the st. branching and leafy and glabrous above, at first erect but becoming prostrate: lvs. mostly basal, glaucous beneath, setulose, ovate-deltoid or ovate-oblong, pinnately parted, the segms. ovate and cut with the terminal part 3-lobed: fls. on slender axillary wiry peduncles twice exceeding lvs., clear yellow: caps. ovate, glabrous, small. Cent. Asia to W. China.

BB. *Fls. red.*

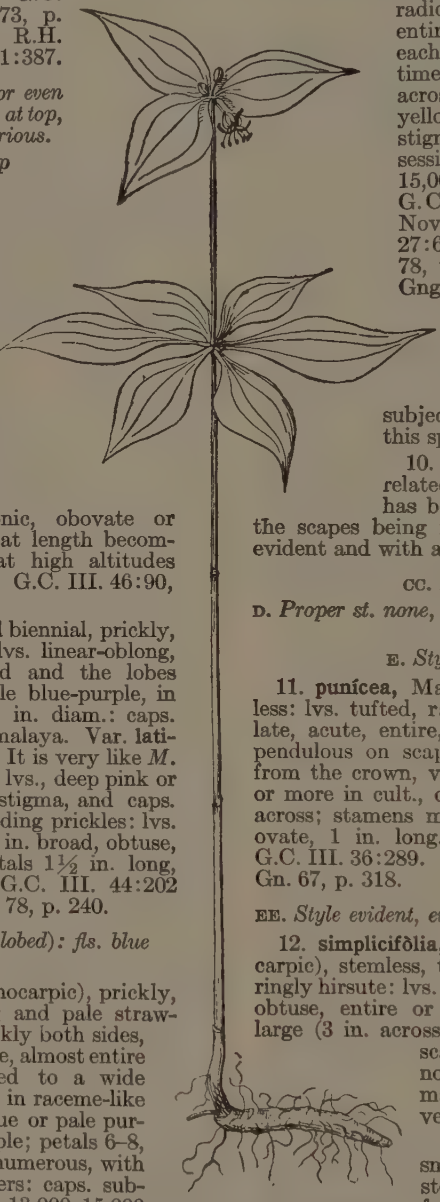
3. **heterophýlla**, Benth. (*Papàver heterophýllum*, Greene). Wind Poppy. Flaming Poppy. Fig. 2341. Annual, glabrous, 1–2 ft.: lvs. pinnate or pinnately cut, the segms. diverse on the same plant and varying from oval and entire or lobed to narrow-linear: fls. brick-red with darker center, satiny texture; petals broadly cuneate-obovate. Calif., Nev., Ore. G.C. III. 29:413; 55:19.—An attractive plant. Var. **crassifòlia**, Jepson (*M. crassifòlia*, Benth.). Blood Drops. Rather smaller and more branching and bearing more fls.: lvs. mostly radical, smaller and thicker. Calif.

2341. Meconopsis heterophylla. (×½)

BBB. *Fls. blue.*

4. **Wállichii**, Hook. (*M. Wallichiàna*, Hort.). Satin Poppy. Tall, 3–6 ft., somewhat glaucous, making a

mound of beautiful cut foliage with rusty hairs, the sts. slender, erect, paniculate: lvs. at base stalked and pinnately parted, the lobes ovate-oblong and sinuate; st.-lvs. sessile, oblong, pinnatifid: fls. satiny, pale blue, with crinkled round-obcordate petals; stamens very many with oblong orange anthers: caps. oblong-elliptic. Mountains (9,000–10,000 ft.), Cent. Asia to W. China. B.M. 4668. F.S. 8:753. G.C. III. 53:147. Gn. 71, p. 626; 73, p. 434; 77, p. 348. G.M. 57:637. R.H. 1912:204. J.F. 3:315. G. 7:449; 31:387.



2342. Medeola virginiana—the Indian cucumber-root. (×½)

AA. *Sts. scape-like and simple (or even none), bearing 1 to many fls. at top, more or less leafy: st.-lvs. various.*

B. *Plant with spines or rigid sharp prickles or hairs.*

C. *Lvs. distinctly lobed: fls. blue or purple.*

5. **aculeàta,** Royle. Probably perennial, somewhat glaucous, sparsely hispid-aculeate (with short scattered prickles), 1–2 ft., leafy: lvs. remotely irregularly pinnatifid, oblong or lanceolate in outline, segms. broad and variously lobed and obtuse or acute, mostly prickly: fls. slender-pedicelled, 2–3 in. across, blue-purple; petals broadly obovate or obcuneate-rotundate: caps. broadly obconic, obovate or oblong, prickly and bristly and at length becoming glabrous. W. Himalaya, at high altitudes (10,000–15,000 ft.). B.M. 5456. G.C. III. 46:90, 91. Gn. 65, p. 384; 75, p. 226.

6. **sinuàta,** Prain. Annual and biennial, prickly, 1–2 ft. or more, the st. leafy: lvs. linear-oblong, obtuse, irregularly sinuate-lobed and the lobes entire, sparsely prickly: fls. pale blue-purple, in few-fld. raceme-like cymes, 2–3 in. diam.: caps. narrow, sparsely prickly. E. Himalaya. Var. **latifòlia,** Prain, is the form in cult. It is very like *M. aculeata*, but differs in less-lobed lvs., deep pink or orange rather than pale green stigma, and caps. longer. plant 1–4 ft., with spreading prickles: lvs. oblong, about 6 in. long and to 2 in. broad, obtuse, irregularly lobed or sinuate: petals 1½ in. long, blue. Himalaya. B.M. 8223. G.C. III. 44:202 (as *M. sinuata*). Gn. 76, p. 316; 78, p. 240.

CC. *Lvs. nearly entire (or not lobed): fls. blue or purple.*

7. **rùdis,** Prain. Annual (monocarpic), prickly, 1½–3 ft., the spines spreading and pale straw-color, rhizome fusiform: lvs. prickly both sides, oblong-lanceolate, obtuse or acute, almost entire or sparingly toothed, narrowed to a wide petiole, glaucescent beneath: fls. in raceme-like cymes, 2½ in. across, bright blue or pale purple, sometimes flushed with purple; petals 6–8, ovate-oblong, obtuse; stamens numerous, with blue filaments and yellow anthers: caps. subglobose or oblong. S. W. China, 13,000–15,000 ft. B.M. 8568.

8. **racemòsa,** Maxim. Very like *M. aculeata*, but with entire lvs.: perennial or biennial with thick elongated root, with yellow prickles, sts. erect or ascending, leafy below, 1–2½ ft.: lvs. glaucous, more or less prickly, the basal ones linear-lanceolate or lanceolate, entire or obscurely sinuate, the st.-lvs. contracted into short winged petiole: fls. deep purple to pale lilac, in long racemose cymes; petals 6 (5–8), obovate, spreading, nearly 1 in. long: caps. with small appressed setæ. Cent. Asia to China, 14,000–15,000 ft. altitude. G.C. III. 42:31; 46:92. G. 34:161. Gn. 68, p. 384; 75, p. 510.—Offered abroad.

BB. *Plant not spiny or prickly, glabrous or only setulose.*

C. *Fls. yellow.*

9. **integrifòlia,** Franch. (*Cathcártia integrifòlia*, Maxim.). YELLOW CHINESE POPPY. Biennial, usually reddish hairy, 1½–3 ft.: lvs. mostly radical, linear-lanceolate, to 8 in. long, entire: fls. on scape-like sts., many on each plant and a half-dozen open at same time, cup-shaped, very large (4–8 in. across), bright sulfur-yellow or primrose-yellow; petals 5–10, broadly obovate; stigmas very many, large and nearly sessile; style wanting. W. China, Thibet, 15,000 and more ft. altitude. B.M. 8027. G.C. III. 36:240; 46:146; 50: suppl. Nov. 11. G.W. 9:534. G.M. 48:287. G. 27:633; 37:8. Gn. 67, p. 286; 73, p. 299; 78, p. 217. G.L. 20:114. F.S.R. 3:80. Gng. 13:279. A.F. 24:781. (Some of these references may apply to No. 10).—A remarkable and showy plant, intro. to cult. something more than 10 years ago from the explorations of E. H. Wilson. A good garden subject. A hybrid is announced between this species and *M. grandis*.

10. **pseudointegrifòlia,** Prain. Closely related to *M. integrifolia*, with which it has been confused in cult.: differs in all the scapes being radical, simple and 1-fld., the style evident and with a narrower stigma. S. W. Thibet.

CC. *Fls. purple or reddish.*

D. *Proper st. none, the fls. borne singly (sometimes twin) on radical scapes.*

E. *Style none; fls. pink-red.*

11. **punícea,** Maxim. Annual (monocarpic), stemless: lvs. tufted, radical, sparsely hairy, ovate-lanceolate, acute, entire, tapering to petiole: fls. large and pendulous on scapes 16–20 in. high, arising directly from the crown, very dark pink and showy; petals 4, or more in cult., ovate-oblong, 4 in. long and 2¼ in. across; stamens many, the filaments flattened: caps. ovate, 1 in. long. W. China, Thibet. B.M. 8119. G.C. III. 36:289. G.M. 48:315. G.W. 10, p. 273. Gn. 67, p. 318.

EE. *Style evident, even though short; fls. blue and purple.*

12. **simplicifòlia,** Don. Annual or biennial (monocarpic), stemless, the foliage radical and tufted, sparingly hirsute: lvs. ovate-lanceolate, acute or somewhat obtuse, entire or toothed, narrowed to petiole: fls. large (3 in. across) and showy, clear blue, on hirsute scapes 12–18 in. high, inclined but not nodding; petals 6–8, ovate; stamens many, with narrow filaments: caps. very narrow. Himalaya. B.M. 8364.

13. **bélla,** Prain. Perennial, very small, the radical lvs. only 2–4 in. long; stemless, the rootstock stout and fusiform: lvs. pinnatisect, the segms, small, ovate-oblong: fls. many, on simple 1-fld. scapes 3 in. or less long, pale blue; petals 4 or 5, broadly ovate, 1¾ in. long and 1½ in. across; stamens numerous, the filaments blue: caps. ¾in. long, pyriform. Himalaya; local. B.M. 8130. G.C. III. 40:197.

14. **Delavàyi,** Franch. Annual (monocarpic), 5–9 in. tall, with long thick and fleshy roots: lvs. all radical, glaucous, lanceolate, attenuate or cordate at base, glabrous above and with sparse colored hairs beneath. fls. solitary on the scapes, half-pendulous, 1½–2 in.

across, deep satiny purple-blue; petals 4 or 5, ovate, obovate or oblong; filaments colored same as petals, anthers orange: caps. 2–3 in. long, on an elongating scape. Yunnan, 11,000–14,000 ft. G.C. III. 50:51. Gn. 77, p. 274.

15. **Hénrici,** Bur. & Franch. Annual or biennial (monocarpic), more or less hairy or sometimes glabrous, low (about 6 in.), the st. very short or practically none, the scapes numerous and 1- or 2-fld.: lvs. linear-oblong or lanceolate, obtuse, entire, attenuate below: fls. large, deep purple-violet, about 3 in. across; petals 6–8; obovate, clawed, spreading; stamens very many, short, the anthers ovate, orange; style slender, exceeding the ovary. W. China.

DD. *Proper st. evident, the flowering branches or peduncles not arising from the base.*

16. **grándis,** Prain. Perennial, 3 ft., pubescent: basal lvs. numerous, somewhat rosulate, ovate-lanceolate, entire or coarsely toothed, the cauline similar and short-stalked or sessile: st. scape-like with fascicled lvs. toward top: fls. 3–5 in. diam., in 3's in umbel-like cymes, brown-purple; petals 6–9; stamens numerous; style short but distinct. Himalaya. G.C. III. 37:369.

M. discígera, Prain. Probably perennial, with golden brown spreading hairs: lvs. in a basal tuft, spatulate, subacute, sparingly toothed, sometimes lobed toward the apex, green above, glaucous beneath: st. scape-like, simple, 1 ft. high: fls. racemose, the petals and sepals not described: caps. bearing a lobed disk. Himalaya.—*M. Fórrestii*, Prain. Allied to M. lancifolia: st. simple: lvs. few, lanceolate or narrow-subspatulate, obtuse or acutish, entire: fls. 3–5, in raceme-like cymes, pale blue; petals oblong. Yunnan.—*M. lancifòlia*, Franch. Annual or biennial, much like M. Henrici, but the deep violet fls. in raceme-like cymes: lvs. narrow-lanceolate or linear-lanceolate, entire or slightly repand; petals broadly obovate: caps. narrow-obconic. China.—*M. nepaulénsis*, Hort. What the cult. plant passing under this name (variously spelled) may be is uncertain. *M. napaulénsis* D.C., is allied to M. Wallichii, but with brownish purple larger fls., and sparsely long-pilose herbage. *M. nipalénsis*, Hook. f., is M. robusta. B.M. 5585. *M. nepalénsis*, Lem., is a form of M. paniculata; and *M. napaulénsis*, Walp., belongs to the same species.—*M. Oliveriàna*, Franch. & Prain. Perennial: st. erect, much branched, 2–3 ft.: lvs. numerous, ovate-oblong, pinnately parted: fls. solitary or twin, probably purple, the petals rounded and nearly 1 in. diam. W. China.—*M. paniculàta*, Prain. Tall perennial, soft-hairy: st. simple or seldom somewhat branched, bearing yellow fls. in lax raceme-like cymes: lvs. linear-lanceolate or oblong, sinuate lobed, coarsely toothed, or rarely pinnatifid: petals entire. Himalaya.—*M. primúlina*, Prain. Annual or biennial, glabrous or sparsely strigose: st. short: lvs. spatulate to linear-oblong, entire: scape nearly radical, 1-fld.; fls. violet-purple, the petals 6–8, the inner ones narrower. Himalaya.—*M. robústa*, Hook. f. & Thoms. Tall annual or biennial, glaucescent, much branched: basal lvs. pinnately parted: fls. racemose or paniculate, sulfur-yellow. Himalaya.—*M. supérba*, King. Annual or biennial, tall and stout: basal lvs. sinuate-lobed: st. simple, bearing white fls. in simple raceme-like cymes. Himalaya.

L. H. B.

MEDÈOLA (named after the sorceress Medea, for supposed medicinal virtues). *Liliàceæ.* Indian Cucumber-Root, from the taste of the edible root. One species, a native perennial herb with 2 whorls of lvs. and small not showy fls. It is offered by some dealers in native plants. Medeola is allied to Trillium, although not suggestive of it in looks. The fls. are umbellate in the upper whorl of lvs., the perianth-segms. all alike, colored and deciduous, stamens 6: fr. a dark, purple few-seeded berry. The *Medeola asparagoides*, Linn., of the older literature, is *Asparagus asparagoides.*

virginiàna, Linn. Fig. 2342. St. slender, 1–3 ft. high, clothed with flocculent deciduous wool, from a short horizontal rootstock: lower whorl of lvs. 5–9, obovate-lanceolate, pointed, netted-veiny, lightly parallel-ribbed; upper whorl of 3–5, smaller, ovate lvs. at top subtending a sessile umbel of small recurved fls. June. Boggy soil, Nova Scotia to Minn., Ind. and southward. B.M. 1316.

L. H. B.

MEDICÀGO (name originally from the country Media). *Leguminòsæ.* Medick. Forage plants, and a few grown for ornament.

Herbs or rarely shrubs, with small pinnately 3-foliolate lvs. and denticulate lfts., and mostly small, purple or yellow fls. in heads or short racemes: stamens 9 and 1, diadelphous: fr. a small spiral or curved, rough or pubescent indehiscent 1- to few-seeded pod: fl. with an obovate or oblong standard and obtuse mostly short keel.—Species probably 50 in Eu., Asia, Afr. Four or 5 species have become weeds in N. Amer. A few are somewhat cult. for ornament. The one important species, from an agricultural point of view, is alfalfa. One species (and perhaps more) is cult. for the odd pods, which are sometimes used by Old World gardeners as surprises or jokes, and are occasionally grown in this country as oddities. See also *Scorpiurus.* Some of the medicagoes simulate clovers in appearance, but the twisted or spiral pods distinguish them. Aside from the following, 2 or 3 species have been used more or less in this country for forage, as *M. hispida*, Willd., and *M. arabica*, Huds., both yellow-fld. annuals. *M. orbicularis*, All., of S. Eu., a very small-fld., yellow annual species with large smooth pods, may be valuable for forage.

2343. Medicago sativa—alfalfa. (×½)

A. *Fls. purple.*

satìva, Linn. Alfalfa. Lucerne. Fig. 2343. Perennial, glabrous, growing erect 1–3 ft. and making a long taproot: lfts. small, linear, oblong to ovate-oblong, prominently toothed toward the top: stipules awl-like, conspicuous, entire: fls. in short, axillary racemes: pods slightly pubescent, with 2 or 3 spirals. Eu.—Now widely cult. as a hay and pasture plant, being to the W. what red clover is to the N. E.; also important eastward. See *Alfalfa*, and books on forage plants.

AA. *Fls. yellow.*

B. *Plant annual and herbaceous.*

lupulìna, Linn. Black or Hop Medick. Nonesuch. Yellow Trefoil. Diffuse, the branches often rooting and becoming 2–3 ft. long, deep-rooted, and difficult to pull up: plant glabrous or slightly pubescent: lfts. oval to orbicular, toothed: stipules broad and toothed: fls. small, light yellow, in pedunculate heads: fr. nearly glabrous, spiral, becoming black. Eu.—Extensively naturalized. It has the appearance of a clover. The yellow clovers with which it is likely to be confounded have larger heads, which soon become dry and papery, and the stipules are entire. It is sometimes used as a forage or hay plant. Of no ornamental value.

prostràta, Jacq. St. prostrate: lfts. linear, dentate at the apex: stipules linear-subulate: pod glabrous, spirally contorted, 2-seeded, black. S. Eu.—Advertised as an ornamental plant. *M. élegans*, a name for a low yellow-fld. plant, may be any one of 4 or 5 species.

scutellàta, Mill. Snails. Erect or spreading, soft-pubescent: lfts. broadly obovate or the upper ones broadly oblong, prominently toothed: stipules falcate, toothed at the base: fls. small, solitary or nearly so: pod large and prominently reticulated, ½in. across, like a snail-shell. Eu.—Grown for the odd snail-like pods, which are used as surprises. See *Caterpillars.* Probably useful also for forage.

BB. *Plant perennial and woody.*

arbòrea, Linn. Tree Alfalfa. Moon Trefoil. Two to 8 ft. tall, with hard black wood: lfts. oval to obovate, light green, toothed at the top: stipules linear-acute, entire: fls. orange-yellow, in rather loose, axillary,

peduncled clusters: pod spiral, 2–3-seeded. S. Eu. L.B. C. 14:1379.—Offered as an ornamental plant in S. Calif.
L. H. B.

MEDINÍLLA (after José de Medinilla y Pineda, governor of the Ladrones). *Melastomàceæ.* Choice warmhouse plants with showy flowers and often with showy bracts and foliage.

Medinilla is distinguished from allied genera (none of which has garden value) chiefly by the curious appendages of the stamens. The stamens are 8, 10 or 12 (twice as many as the petals), the anterior connective 2-lobed or 2-spurred, the posterior one usually setose or 1–2-lobed or 1-spurred: branching shrubs, erect or climbing: lvs. mostly opposite or whorled, entire, often fleshy: fls. white or rose, with or without bracts, in panicles or cymes: fr. a berry crowned by the calyx-limb.—Species 125 and more, in tropical parts of E. Asia, Afr., and the Pacific region, many of them in the Philippines. Those prominently described below have opposite lvs. and mostly 5-merous fls.

Medinillas are amongst the handsomest and most striking of flowering plants, and being of free growth should be given a place in all tropical collections. To succeed with them, a position affording all the light possible should be given them. However, they will not stand strong sunshine, and it is advisable that they be shaded with cheese-cloth the greater part of the year. If they are grown under a heavy shade, they are not inclined to flower well. Cuttings of half-ripened wood, taken in spring, is the best means of propagation. These may be potted singly, in suitable pots, in a mixture of finely sifted peat and sand, with a little powdered charcoal added. Place them in a tight case, and keep fairly moist, care being taken that the air does not become stagnant. The night temperature should not be less than 70°. The cuttings will be rooted in about a month, when they may gradually be given more air and finally transferred to a position in the tropical house. In the earlier stages of growth, the points of the shoots may be stopped by pinching to encourage breaks. Later on they will branch freely of themselves. A good fibrous loam with a third of sharp sand, adding a little charcoal about the size of beans, is the best potting material. Pot moderately firm, as this tends to make a shorter-jointed growth and firmer wood, which is indispensable for success in flowering. Three inches of a shift may be given each time they are potted, as they root freely, but strict attention must be given to drainage, as they require plenty of water during their growing season. A night temperature of not less than 68° is necessary while they are in active growth. Syringe freely on all bright days, especially the under side of the foliage, as red-spider is likely to get a foothold. As autumn approaches, gradually lower the temperature to 60° by night, and gradually withhold water, giving just enough to keep the leaves plump. This ripens the wood for flowering. While the flowers are forming, as dry an atmosphere as possible should be maintained. After flowering, the plants may be pruned into shape, and any repotting done that is necessary. Medinillas may be retained in the same-sized pot for years, after they have attained the desired size, by shaking out a portion of the old soil each year, when repotting, and feeding liberally during the growing period with manure water. *M. magnifica* is the handsomest form, but *M. Teysmannii* (*M. amabilis*) is also a fine variety, the panicles being erect instead of pendulous, which is the habit of the former. *M. Curtisii* is quite distinct from the above. It grows well in a greenhouse temperature of 50° to 55° and begins to flower in the fall, lasting through the winter. The leaves are much smaller than in the above two species. It makes an excellent bush plant and should be better known. Mealy-bug and scale are liable to attack the plants and they must be kept in check as soon as detected. (George F. Stewart.)

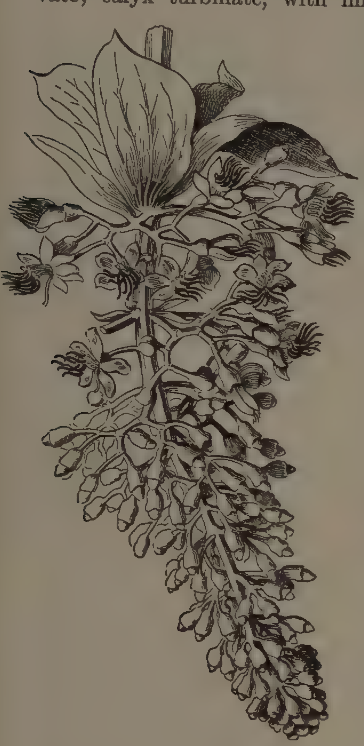
2344. Medinilla magnifica. A young specimen.

A. *Fls. coral-red or rosy pink.*

magnífica, Lindl. Figs. 2344, 2345. Evergreen shrub: lvs. with 9–13 nerves, which run from various points along the midrib to the margin or apex, ovate or ovate-oblong: bracts 1–4 in. long. Philippines. B.M. 4533. F.S. 6:572; 9:968 (splendid). Gn. 51, p 394. G.C. II. 2:421; III. 49:226. R.B. 33, p. 72; 36, p. 54. G. 31:357. J.F. 1:56, 57; 3:298. G.W. 1, p. 6; 10, p. 431. R.H. 1857, pp. 319, 343; 1896, pp. 102, 103. A.F. 7:1047.—Other interesting features are the whorled branches, each one 4-ridged or winged, and the dense ring of short fleshy processes at the joints between the lvs. It can be prop. by seeds or cuttings of young wood in heat. *M. magnifica* is one of the most gorgeous tropical plants in cult. It has handsome broad, shining, leathery foliage and coral-red 5-petaled fls., each about 1 in. across, which are borne in pendulous pyramidal panicles sometimes a foot long, and bearing 100–150 fls. The axis and branches of the panicle are pinkish, and the same color tinges the large showy bracts, which are sometimes 4 in. long. Hooker says: "Its most beautiful state is, perhaps, before the full perfection of the fls., when the large imbricated bracts begin to separate and allow the buds to be partially seen. As the expansion of the blossoms advances, the upper bracts fall off, but the lower ones remain and become reflexed." This remarkable plant flowers copiously when only 2 or 3 ft. high, and a large well-kept specimen in bloom is a worthy ambition of a gardener. The numerous long bent purple anthers, with their yellow filaments, form an additional feature of interest.

Téysmannii, Miq. (*M. amábilis,* Dyer). Exceeds *M. magnifica* in size of fls., but lacks the beautiful colored bracts: glabrous: sts. with 4 crisped or crenulate wings: lvs. very large (12 in. long and 6–8 in. wide), sessile, obovate-oblong or elliptic-oblong, acute and often concave, wavy-margined, 5-nerved: panicle pyramidal, erect, bracts none; fls. rose-colored, 1½–2 in. diam.; calyx truncate or obscurely lobed; stamens 10, upcurved, with pale violet anthers. Celebes, New Guinea. B.M. 6681. G.C. II. 1:373; 17:561.

javanénsis, Blume. Erect shrub or tree with smooth 4-sided branches: lvs. large, sessile, elliptic-ovate, 5-nerved, entire, acute, tinged red beneath: panicle small and compact, lateral and terminal, the bracts small and deciduous; fls. pale rose-color; petals obovate; calyx turbinate, with minute teeth; filaments white and anthers dark purple. Java. B.M. 4569. J.F. 1:96.



2345. Medinilla magnifica. (×⅓)

AA. *Fls. white.*

Cúrtisii, Hook. Shrub with slender drooping branches: lvs. with 2 nerves beside the midrib which run from the base to the apex of the lf., sessile, oblong or ovate-oblong, acuminate: bracts minute, at the base of the spreading branches: fls. ivory-white, with purple anthers, to ⅔in. across; calyx globose and fleshy, with a short limb, petals nearly orbicular. Sumatra. B.M. 6730. G.C. II. 20: 621. G.Z. 28, p. 194.

chionántha, Stapf. Glabrous shrub with terete gray-brown branches: lvs. lance-oblong, acuminate, narrowed into a very short decurrent petiole, 3-nerved: cymes axillary, somewhat umbellate, the bracts minute and acute; fls snow-white; petals broadly elliptic, obtuse, fleshy, ⅔in. long. Malay Peninsula.

There are many beautiful plants in this genus, but only a few of them are in cult. The following may be expected: *M. Sieboldiàna*, Planch. Lvs. oblong, fleshy, opposite, strongly 5-nerved: fls. white, ¾in. across, with purple stamens, in a drooping panicle. Moluccas. B. M. 4650. R. B. 36, p. 38.—*M. speciòsa*, Blume. Dichotomous or trichotomous, the branches 3- or 4-angled: lvs. mostly whorled, nearly sessile, oval or oval-oblong, 5- or 7-nerved: fls. rose in a dense terminal panicle. Java. B. M. 4321. F. S. 5:482.—*M. venòsa*, Blume. Branches terete: lvs. relatively small, short-petioled, oblong-acute, 7-nerved, rusty colored above, opposite: fls. rose-color, in few-fld. cymes; petals oblique-obovate, acute. Malaya. R. B. 36, p. 38.

WILHELM MILLER.
L. H. B.†

MEDLAR: *Mespilus.*

MEGACLÌNIUM (Greek, *large bed*, because of the ample rachis). *Orchidàceæ.* About 50 species of African epiphytic orchids, nearly all tropical, requiring the treatment given Bulbophyllum, which they resemble in habit but from which they are distinguished by having the bracts and fls. attached on either side a flattened rachis and the lateral sepals shorter than the curved free dorsal sepal: herbs with strong creeping rhizome, pseudobulbs usually globose or ovoid and bearing 1 or 2 lvs.: fls. small, yellowish, brownish, purple, variously spotted, on the almost leafy end of the scape that arises from the base of the pseudobulbs; petals smaller and narrower than the sepals; lip jointed to the foot of the column, mobile, entire, denticulate or 3-lobed; column short, winged on both sides: scape usually only a few inches high, sometimes 18 in.

M. bùfo, Lindl. (Bulbophyllum bufo, Reichb. f.). Rachis green, long-linear, 8–9 in. long and ½in. wide, bearing small brownish fls. with darker spots: lip dark purple, flat, the base ovate-orbicular. Sierra Leone. G. C. 1841:348.—*M. Clárkei*, Rolfe. Rachis light green in center and margined and spotted purple-brown, 6–7 in. long, falcate-ensiform, obscurely repand-crenulate: fls. purple-brown specked on green; lip recurved, the base ovate. W. Trop. Afr.—*M. ebúrneum*, Pfitz. Scape as long as lvs., and rachis as long as scape and irregularly dilated: fls. and rachis yellowish white; ends of petals and the dorsal sepal yellow. W. Afr.—*M. falcàtum*, Lindl. (Bulbophyllum falcatum, Reichb. f.). Rachis brown-green, linear-oblong and somewhat falcate, acute, thin-margined, 2–4 in. long: fls. dark brown-red on upper parts and greenish yellow on lower segms.; lip triangular oblong, obtuse. Guinea. B. R. 989.—*M. leucorhàchis*, Rolfe. Rachis white, ⅓in. broad and 3 in. long, falcate-ensiform, obscurely crenulate: fls. velvety yellow; lip recurved, the broad base fimbriate. Upper Guinea. B. M. 7811.—*M. lutéscens*, Rolfe. Scapes less than 2 in. long: rachis very narrow, 1¼ in. or less long: fls. honey-yellow, small and nearly sessile: resembles M. minutum, but the rachis much narrower and the dorsal sepal acuminate. W. Afr.—*M. máximum*, Lindl. Rachis purple, 4–5 in. long and ½in. wide, ensiform, undulate, the scapes 1–1¼ in. long with tubular sheaths: fls. purple; lip oblong, obtuse, the base broad and denticulate. Guinea. B. M. 5936 (as M. purpuratum).—*M. minùtum*, Rolfe. Very small, the scape only 1½ in. long, the rachis purple-brown, oblong, crenulate, bearing about a dozen blooms: fls. dull maroon and greenish yellow, fleshy; lip cordate-ovate, obtuse, reflexed at apex. Upper Guinea. B. M. 7314.—*M. platyrhàchis*, Rolfe. Rachis much dilated, 4–6 in. long and 1 in. broad, crenulate, greenish yellow, spotted white and brown, lengthening in bloom: fls. many, yellow-green; lip fleshy and tongue-shaped, recurved, the lateral lobes small. Cent. Afr. B. M. 7946.—*M. purpuràtum*, Lindl.=M. maximum.—*M. purpureorhàchis*, Wildm. Large, the scapes lateral and stout, 12–14 in. long: rachis broad and flat, undulate and slightly twisted, purple-spotted: fls. brown, velvety outside; lip orbicular-ovate, recurved and obtuse, flattened. Congo. B. M. 8273.—*M. scabérulum*, Rolfe. Rachis dull white, shaded green and marked purple: fls. dull purple, the sepals shaded whitish green at base. S. W. Extra-trop. Afr.—*M. ugándæ*, Rolfe. Scape about 5 in. long: rachis oblong, half length of scape, light green and heavily marked with purple-brown: fls. small, with light green petals and sepals similar in coloring to the rachis. Uganda.

L. H. B.

MEGARRHÌZA: *Echinocystis.*

MEGÁSEA: *Saxifraga.*

MEIBÒMIA: *Desmodium.*

MELALEÙCA (Greek, *melas*, black, and *leukos*, white; from the black trunk and white branches of one of the species). *Myrtàceæ.* Shrubs and trees, often with showy bloom, of high ornamental value for warm temperate regions; especially useful where drought-resistant shrubs are needed.

Leaves alternate, rarely opposite, entire, lanceolate or linear, flat or subterete, with 1–3 or many nerves: fls. in heads or spikes, rarely scattered, each sessile in the axil of a floral lf., their parts in 5's; calyx-tube subglobose; lobes imbricate or open; petals spreading, deciduous; stamens indefinite in number, more or less united at their bases into 5 bundles opposite the petals; anthers versatile, the cells parallel and bursting longitudinally; ovary inferior or half-inferior, inclosed in the calyx-tube, usually with many ovules in each cell; maturing into a persistent caps. Related to Callistemon but distinguished by the united filaments: shares with that genus the name of bottle-brush.—About 100 species of Australian shrubs and trees, some inhabiting salty ground and swamps, others occupying semi-arid slopes of the interior. Grown as specimen and lawn plants, the larger species also for street trees in Calif. and Fla.: *M. Leucadendron* and *M. ericifolia* are recommended for fixing muddy shores and for planting in alkaline soils. The timber is close-grained, hard, and durable. Sixteen species are described and figured in Univ. Calif. Pub. Bot. 4:27–34. For cult. see *Callistemon.*

A. *Infl. a cylindric spike (rarely head-like in Nos. 5 and 11), or fls. somewhat scattered.*

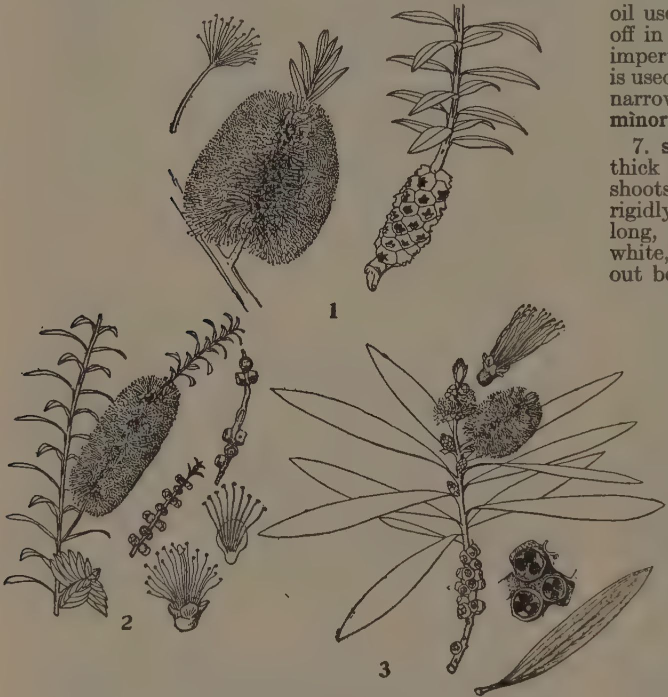
B. *Fls. red or scarlet.*

1. **hypericifòlia**, Smith (*M. oppositifòlia*, Hort.). Fig. 2346. Tall glabrous shrub: lvs. opposite, lanceolate or

oblong, ¾–1¾ in. long, with prominent midrib and dots beneath: fls. rich red, in spikes 2 in. long and about as wide, the axis growing out as a leafy shoot; stamens ¾–1 in. long, including the claw of about ½in.: fr. sessile by a broad base. May–Oct. L.B.C. 2:199.—One of the most popular, with pleasing foliage and gorgeous bloom.

2. **laterítia,** Otto. Graceful shrub with many slender branches, 6–12 ft.: lvs. alternate, linear, acute, ½–¾in. long, quite nerveless: fls. rich scarlet, in cylindric spikes about 2½ in. long and forming the base of leafy branches; stamens ¾in. long, the claw very short: fr. sessile.—Grown for its graceful habit and for the soft color of its fls.

3. **Wìlsonii,** F. Muell. Tall elegant shrub, glabrous or slightly pubescent: lvs. opposite, imbricate on twigs, linear, acute, ¼–½in. long: fls. red, scattered or in loose spikes; stamens ½in. long: fr. sessile. B.M. 6131.



2346. Melaleucas: *1,* M. hypericifolia; *2,* M. decussata; *3,* M. Leucadendron.

BB. *Fls. white, blue, lilac, or pink.*

C. *Lvs. mostly opposite.*

4. **linariifòlia,** Smith. Tall shrub or tree, pubescent only on young parts: lvs. rigid, broad-linear, acuminate, mostly 1–1¼ in. long, the midrib prominent beneath: fls. white, in pairs in spikes 1–1½ in. long, these at first terminal but the shoot soon continuing; stamens ½–¾in. long, the long claws emitting short filaments along their entire length: fr. narrow at base but sessile.

5. **decussàta,** R. Br. Fig. 2346. Spreading shrub, to 20 ft., bright green and glabrous: lvs. lanceolate to oblong, narrowed at base, ¼–½in. long, 1 line wide: fls. lilac, in cylindric spikes 1 in. or less long, the axis growing out as a leafy shoot, or the clusters globose and lateral or terminal when the fls. are sterile; stamens ¼in. long, very shortly united in bundles of 10–15: fr. broad at base, partly embedded in the thickened rachis. B.M. 2268. L.B.C. 13:1208.—Grown in large grounds, where the spreading branches and pendulous twigs may develop to best advantage.

CC. *Lvs. mostly alternate or spiral.*

D. *Length of lvs. mostly over ½in.*

6. **Leucadéndron,** Linn. (*M. Cajupùti,* Roxbg. *M. latifòlia,* Raeusch). Cajuput Tree. Punk Tree. Swamp Tea Tree. Fig. 2346. Large tree with thick spongy bark and pendulous branchlets (branches rigid and erect in small plants), either glabrous or the young shoots silky: lvs. elliptic or oblong, tapering to each end, 2–4 or 8 in. long, ½–¾in. wide, with 3–7 parallel nerves and numerous cross-veinlets: fls. creamy-white (varying to pink and purple in Austral.); the spikes 1½–4 in. long, 1 in. wide, the axis growing out only after flowering; stamens nearly ½in. long. June–Oct. G.M. 40:798. Bot. Cook's First Voy. 112. Maiden, For. Fl. N. S. W. 15.—This tree withstands salt-water, wind, drought, and slight frosts. The lvs. of certain forms yield the well-known green aromatic cajuput oil used in medicine. The bark is pale buff and peels off in many thin layers; it is very durable and almost impervious to water; it is valuable for packing frs. and is used for roofs and boats. A low, pyramidal form with narrow lvs. and silky fls. is sometimes listed as var. **mìnor,** Hort.

7. **styphelioìdes,** Smith. Becoming a tall tree, with thick spongy bark, glabrous except the silky young shoots and infl.: lvs. ovate, sessile by a broad base, rigidly acuminate, often somewhat twisted, ½–¾in. long, nearly ¼in. wide, many-nerved: fls. creamy white, in dense spikes 1 or 2 in. long, the axis growing out before flowering is over; stamens 4 lines long: fr. globose, crowned by the persistent calyx-teeth.—Grown at San Diego; a subject worthy of much wider use.

8. **armillàris,** Smith (*M. álba,* Hort.). Tall graceful shrub with slender leafy twigs, glabrous throughout: lvs. narrowly linear, ½–¾in. long, not 1 line wide, the tip very slender and usually curved: fls. white, in cylindric spikes often 2 in. or more long, the axis protruding and leafy before the buds open; stamens ¼in. long, the ribbon-like claw about equaling the distinct filaments: caps. with broad base partly embedded in the rachis. Bot. Cook's First Voy. 114.—The best of the white-fld. melaleucas, especially because of its slender drooping branchlets and absence of barren twigs. The knotted fr.-clusters, so objectionable in some species, are not evident in this.

DD. *Length of lvs. mostly ½in. or less.*

9. **parviflòra,** Lindl. (*M. Preissiàna,* Schau.). Tree or tall shrub, glabrous or the young parts pubescent: lvs. thick, rigid, lanceolate or broadly linear, very acute, about ½in. long, the nerves obscure: fls. white, in loose spikes 1 in. or less long: fr. globose, narrowed to the base. June–Oct.—*M. armillaris* and *M. ericifolia* are often erroneously labeled *M. Preissiana* in Calif. gardens and nurseries.

10. **Huègelii,** Endl. Erect rigid shrub, 6–15 ft., nearly glabrous: lvs. spirally arranged, appressed, overlapping, sessile, ovate, acute, ¼in. or less long, striate with 3–7 nerves: fls. white (or buds pink), in dense spikes 1–5 in. long by about ¾in. wide, the rachis growing out before the buds open; stamens 4 or 5 lines long, the conspicuous claw ending in 7–11 filaments: frs. globose, with broad base partly embedded in the rachis, crowded into a cylindric spike.—Interesting chiefly because of its oddity.

11. **ericifòlia,** Smith. Small tree, either glabrous or pubescent, the bark thick and soft: lvs. not rigid, usually recurved from the middle, narrowly linear or nearly cylindric, rather obtuse, about ½in. long: fls. yellowish white, the spikes ½–1 in. long and less than ½in. wide, the rachis soon growing out, or the sterile fls. in nearly globular terminal heads; stamens ¼in.

long, each claw bearing about 7 terminal filaments: fr. with broad base partly embedded in the rachis.—Resembles an arboreous heath. Used to a limited extent in Calif. as a lawn tree.

AA. *Infl. a terminal globose head, the rachis seldom growing out until after flowering.*

12. **nesóphila,** F. Muell. Glabrous shrub or tree, to 35 ft., with thick spongy bark exfoliating in broad strips: lvs. alternate, thick, obovate-oblong, obtuse but often mucronate, ½–1 in. long, about ¼in. wide, obscurely 1- or 3-nerved: fls. pink or rose-color, the heads 1 in. or more thick; stamen-claw short: frs. smooth, congested in knot-like masses. May–Sept.—A very rapidly growing species used for large shrubberies and (in S. Calif.) for shade above seats in parks. The persistent caps. are unsightly in small grounds.

13. **nodòsa,** Smith. Tall, nearly glabrous shrub: lvs. nearly awl-like, rigid, straight, ½–1 in. long: fls. pale yellow, in many small heads scarcely ½in. thick: frs. in small inconspicuous heads. Bot. Cook's First Voy. 115.

14. **incàna,** R. Br. Tall shrub, the young twigs, flowering branches, and young lvs. ashy-pubescent: lvs. alternate, rarely opposite, spreading, linear to lanceolate, acute, ¼–½in. long, mostly 1-nerved: fls. yellowish white, in dense ovoid or oblong spikes about ¾in. wide; stamens shortly united in bundles of 3–9: frs. in dense cylindric spikes ¾–1 in. long. B.R. 410.

M. fúlgens, R. Br. Stands next to M. lateritia in botanical characters but lvs. mostly opposite: fls. dark red; stamens 1 in. long, the ribbon-like claw splitting into numerous filaments. B.R. 103. R.H. 1895:232.—*M. genistifòlia*, Smith. Near M. lateritia: lvs. alternate, narrow-lanceolate, rigid, the upper finely striate: stamens about ¼in. long.—*M. micromèria*, Schau. Stands next to M. incana: lvs. minute, scale-like, densely clothing the st. Once grown at Santa Barbara.—*M. tenélla*, Benth. Near M. nodosa: lvs. scattered or in 3's, linear, ¼in. long: stamens about 2 lines long.

HARVEY MONROE HALL.

MELÁNTHIUM (Greek, *black flower;* from the color which the persistent perianth assumes on fading). *Liliàceæ.* Leafy perennial herbs 2–5 ft. high, with thick rootstocks: lvs. linear to oblanceolate, the lower ones sheathing: fls. greenish, white or cream-colored, borne in a large open terminal panicle; segms. of perianth 6, separate, clawed, biglandular; stamens adnate to segms.; styles 3, subulate: fr. a 3-celled caps.—Species 4, E. U. S.

virgínicum, Linn. BUNCH-FLOWER. St. rather stout, to 5 ft., leafy: lvs. linear, 1 ft. or less long: panicles 6–18 in. long; fls. 6–10 lines across, greenish yellow, double gland at top of claw. July. Marshy woodlands and meadows from New England to Fla. and Minn. to Texas. B.M. 985 (as *Helonias virginica*).—A showy and striking plant, good for bog-planting and colonizing. The other species appear not to have been offered in the trade.

L. H. B.

MELASPHÆRULA (a little black sphere; referring to the bulblets or the seeds). *Iridàceæ.* One species from the Cape of Good Hope, a small bulbous plant procurable from Dutch bulb-growers. It belongs to the Ixia tribe, in which the fls. are spicate, not fugitive, and never more than 1 to a spathe. It resembles Ixia in having a regular perianth and simple style-branches, but belongs to a different group of genera in which the stamens are 1-sided and arched. Perianth slit nearly to the ovary, the segms. oblong-lanceolate or lanceolate and very acuminate; stamens short, attached in base of perianth; style short and filiform: caps. 3-lobed, loculicidal. Treated as ixias in cult.

gramínea, Ker (*Gladìolus gramíneus*, Linn. f.). Corm globose, ½in. diam.: st. very slender, 1 ft. or more long: lvs. about 6 in a 2-ranked, basal rosette, linear, ½–1 ft. long: spikes few-fld., panicled; fls. yellowish green, veined with purplish black, ½–¾in. across. Spring. Coast region of S. Afr. B.M. 615.

L. H. B.

MELÁSTOMA (Greek for *black* and *mouth;* said to allude to the color left in the mouth when the berries of some species are eaten). *Melastomàceæ.* Woody greenhouse plants.

This genus, which gives name to the great family Melastomaceæ, with more than 2,000 species, is little known in cult. It is not the most important genus of the family, either horticulturally or in number of species. Cogniaux (DC. Monogr. Phaner. 7) admits 37 species. The larger part of melastomaceous plants are of Trop. Amer., but the true melastomas are natives to Trop. Asia, Austral. and Oceanica. They are shrubs or rarely small trees: lvs. opposite, petiolate, oblong or lanceolate, thick and entire, strongly nerved lengthwise, often handsomely colored: fls. solitary or fascicled on the ends of the branches, purple or rose (rarely white), large and showy; calyx mostly 5-lobed; petals usually 5 and often unequal, ciliate on the back; stamens 10 as a rule, very strongly unequal, part of them being short and small: fr. a leathery or fleshy berry, breaking irregularly, 5–7-loculed, with many small spiral seeds. Nearly all tropical melastomaceous plants require a high temperature, partial shade and considerable moisture.

The melastomas are seldom seen in greenhouses, yet on account of the showy flowers of some of the species all representative collections of plants should have a few of them. The plants known under this name to gardeners are likely to belong in part to other genera (specially to Miconia) but they agree in cultural requirements. They are not difficult to grow, and a little effort bestowed on them will repay the grower when flowering time arrives. Cuttings may be secured from the half-ripened wood in spring. The best way is to place each one in a small pot, in equal parts of peat and sand. Plunge the pots in a bed with 70° to 75° of bottom heat, keeping them shaded from the sun. It is better to inclose them in a tight frame, or case, to avoid draughts. When rooted, place the plants in a greenhouse near to the glass, in a night temperature of 65°. When they become inured to their position, pinch the heart out of them to encourage breaks. Shift them along as they require it. The compost from now on should be equal parts of peat and loam, with about a third of sand, and a little broken charcoal also may be added. See that the receptacles are well drained, as when the plants are growing they require plenty of water, which should have a free outlet to prevent stagnation. If peat cannot be procured, they will do very well in a good fibrous loam to which a third of leaf-mold has been added.—The first season the aim should be to procure a well-shaped plant and this may be done by cutting back the strong shoots, allowing the weaker ones to grow longer to acquire strength. Keep them protected from the sun with a slight shade, such as cheese-cloth, to prevent the foliage from burning. In winter a somewhat lower temperature may be given and a rather dry atmosphere maintained. When the plants are established in their flowering pots, applications of weak liquid manure may be given once a week until they show flower.—In the growing period, occasional syringings with clean water may be made to the under side of the foliage to prevent red-spider. Other insect pests may be kept in check by fumigation with hydrocyanic gas, at the rate of one-half ounce to the 1,000 cubic feet. The atmosphere and plants should be on the dry side, and the temperature around 60° when the operation is performed.—Some of the species flower in winter. *M. decemfidum* is an example. Others flower in summer, among which may be mentioned *M. corymbosum*, *M. denticulatum* (see *Miconia*), and *M. malabathricum.* (George F. Stewart.)

A. *Lvs. strongly 5-nerved.*

decémfidum, Roxbg. (*M. sanguíneum*, D. Don. *M. malabáthricum*, Sims, not Linn.). Three to 4 ft.: branches subterete and hirsute: lvs. lanceolate or lance-oblong, long-acuminate, the nerves (or at least some of them) and the petioles often red: fls. 1–3, large, nearly or quite 2 in. across, the petals rose-colored and retuse. Java to China. B.M. 529; 2241.

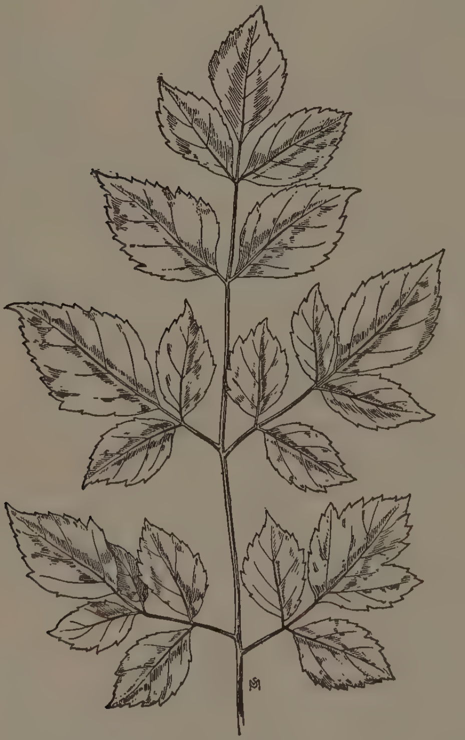
normàle, D. Don. About 5 ft., the hairy young branches brown-gray: lvs. petiolate, ovate-oblong, 5-nerved, yellow-felted beneath: fls. lilac-rose, several together at ends of bractless branches; calyx yellow-pubescent, the lobes linear-subulate; petals ovate, 1 in. long. India to Polynesia. R.H. 1910:332.

AA. *Lvs. strongly 7-nerved or more.*

cándidum, D. Don. Branches 4-angled, hoary, the younger ones pubescent, as also the petioles: lvs. ovate-acute, setulose above, villose beneath: fls. 3–7 in a cyme, rose-colored (sometimes white?), about the size of those of *M. decemfidum;* calyx-lobes shorter than the tube. S. China. *M. malabathricum,* B. R. 672(?).

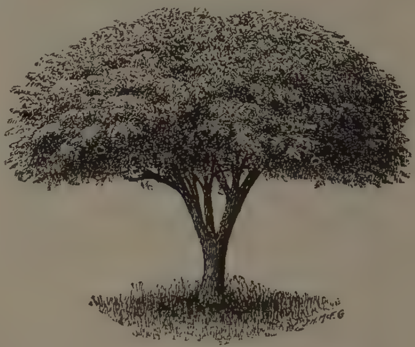
malabáthricum, Linn. (*M. Bánksii,* Cunn.). Differs from the last in having the calyx-lobes about equal to the tube, or sometimes even longer: lvs. oblong or ovate-oblong, acute or short-acuminate, sparsely setulose, above and beneath: fls. corymbose, purple, much smaller than in the last two. E. India to Austral.—Probably the *M. malabathricum* of horticulturists is one of the above species. Not known to be in the American trade.

corymbòsum, Sims (properly **Amphiblémma cymòsum,** Naudin. *Melástoma cymòsum,* Schrad.). Branches terete, glabrous: lvs. large, petioled, the blade 5–6 in. long, cordate-ovate, short-acuminate, glabrous, 5–7–9-nerved, satiny green, sharply serrulate: fls. bright purple, in rather close terminal branching corymbs; petals oval, paler beneath; calyx-lobes ovate-triangular, ciliate; stamens 10. Upper Guinea. B.M. 904; 5473. L.B.C. 10:984.—To the genus Amphiblemma, Cogniaux admits 5 species. They are herbs or shrubs, of the Sonerila group or subfamily, with isomerous fls.: herbs or small shrubs of W. Trop. Afr., with fls. in simple or branched scorpioid cymes: petals 5; stamens 10, very unequal; ovary 5-celled and hollowed at top: caps. turbinate, 5-valved at top, with minute seeds: lvs. membranaceous, long-petioled, ovate-acuminate, 5- or more-nerved, serrulate. L. H. B.



2347. Leaf of Melia Azedarach. (×⅙)

MÈLIA (ancient Greek name). *Meliàceæ.* BEAD-TREE. Trees, from 30 to 40 feet high, some of them much planted South for shade and ornament; sometimes bushes. Leaves deciduous, large, doubly pinnate or once-pinnate, the lfts. acuminate, glabrous: fls. in graceful panicles; sepals 5–6, imbricated; petals 5 or 6; stamens monadelphous, 10–12, of two lengths; ovary with several locules, topped with a single style: fr. a small indehiscent drupe.—Species few, of Asia and Austral.



2348. Umbrella tree—Melia Azedarach var. umbraculiformis.

A. *Lvs. more than once-pinnate.*

Azédarach, Linn. CHINA-TREE. CHINA-BERRY. PRIDE OF INDIA. Fig. 2347. Tree, to 40 ft. and more, making a thick trunk with furrowed bark: lvs. 2-compound, to 3 ft. long, stalked; lfts. many, ovate, oval or elliptic, acute, sharp-toothed or lobed: fls. purplish, in open panicles 4–6 in. long; petals oblanceolate or narrow-oblong, obtuse; sepals acute; ovary 5-celled: drupe nearly globular, yellow and smooth, ½–¾in. diam. Himalayan region, 2,000–3,000 ft. altitude, and probably native elsewhere in Asia; now widely planted. B.M. 1066. S.I.F. 2:35 (as *M. japonica*).—It has become naturalized throughout the S.; the northern limit of its hardiness is about Norfolk, Va., or somewhat southward, on the coastal plain area; it is luxuriant in N. C., except in the Piedmont country. The tree grows with great rapidity, and forms one of the most desirable shade trees, both from the bright green tint of the foliage, which is retained until late in the autumn, and also from the fragrance of the numerous lilac-colored fls. which are produced in April. These are succeeded by an abundant crop of berries, of a yellowish translucent color, which are readily eaten by cattle and birds. In some countries, the seeds are used for the making of rosaries. The wood, although coarse, is very durable. The tree can withstand a low temperature, but a cold of zero will injure or kill it. Several forms have been found, a white-flowering and one with the segms. of the lfts. cut in narrow divisions. These forms are not constant, the seedlings frequently reverting to the typical species. In all forms of *M. Azedarach,* the lvs. are 2- or 3-pinnate, the ultimate lfts. ovate or lanceolate, and varying from serrate to very nearly entire.

Var. **umbraculifórmis,** Berckm. (var. *umbraculífera,* Hort.). TEXAS UMBRELLA TREE. Fig. 2348. Lfts. are less broad than in *M. Azedarach,* and the branches erect, and, in a manner, radiating from the trunk, the drooping foliage giving the tree the appearance of a gigantic umbrella. Mn. 8, p. 73. F.E. 26:187. G.F. 7:95.—The first tree that came to notice is said to have been found near the battlefield of San Jacinto, Texas, but with no record of its intro. there. If the fls. are not cross-pollinated with the common sort, the percentage of seedlings which reproduce the exact umbrella shape seldom varies; hence it is supposed by some to be a distinct species.

sempérvirens, Swartz (*M. Azédarach* var. *sempérvirens,* Linn.). A low-growing tree with lvs. deeply incised, the lfts. the shape of those of *M. Azedarach:* fls. in axillary panicles, small, light lilac, fragrant, in constant succession. A greenhouse species, and a beautiful tree of distinct habit in S. Fla., where it is rapid-growing, holding its lvs. well into winter and blooming at intervals throughout the year. It is there prone to send up suckers and to prop. itself unduly from seeds. *M. sempervirens,* Swartz, is a widespread plant in the W. Indies and elsewhere. B.R. 643.

floribúnda, Carr. (*M. Azédarach* var. *floribúnda,* Morr. *M. japónica* var. *semperflòrens,* Makino). By some considered to be a precocious and very floriferous form of *M. Azedarach,* but the plant grown in this country under this name and as *M. semperflorens* (and which is probably the same as Carriere's *M. floribunda*) is a bushy species, not tree-like, and should receive further study. In S. Fla. it is a "small awkward shrub, never reaching above 10 ft. and seldom branching." In S. Calif. it rarely reaches above 8 ft. and suckers continually; by cutting down to the ground the sts. that have bloomed, it can be had in flower nearly all the year. *M. floribunda* is said to begin to bloom at 1–2 ft., and to flower the second and third years from seed. The lfts. are lanceolate or oblong-lanceolate rather than ovate, very gradually taper-pointed. Perhaps Japanese. R.H. 1872:470. B.H. 30:176.

AA. *Lvs. once-pinnate.*

Azadiráchta, Linn. (*Azadiráchta ìndica,* A. Juss., and by some recent writers kept generically distinct). Large tree, sometimes 50 ft.: lvs. broad, pinnate, with 9–15 lance-acuminate, oblique, more or less serrate lfts.: fls. white, fragrant, very small, 5-merous; petals ciliate: drupe ½–¾in. long, oblong, the seeds yielding oil: foliage crowded near the ends of the branches. India.—Not hardy in the Cent. S.

M. japónica, Don, is by Hemsley (Fl. China) referred to M. Azedarach; *M. japónica,* Hassk., is by some referred to M. Azadirachta, but is perhaps distinct; apparently these plants are not in the trade.

L. H. B.†

MELIÁNTHUS (Greek, *honey-flower*). *Melianthàceæ;* formerly included in *Sapindàceæ.* Evergreen shrubs of South Africa, to be grown out-of-doors in southern California and similar climates.

Leaves alternate, stipulate, odd-pinnate; lfts. unequal-sided: fls. in axillary and terminal racemes, secreting honey plentifully; calyx laterally compressed, with or without a sac-like protuberance at the base, with a nectar-bearing gland within; petals 5, the anterior one abortive; stamens 4, didynamous. *M. himalayanus,* Wall., is *M. major,* which has been intro. into S. Asia.—About a half-dozen species, strong-scented.

A. *Lfts. entire.*

pectinàtus, Harv. (*M. Trimeniànus,* Hook. f.). Rigid shrub, with densely set pectinate-pinnate lvs. on short twigs, the rachis winged: lfts. 8–10 pairs, linear, entire, with revolute margins, white-tomentose beneath: fls. dull red, in more or less whorled racemes, the peduncles purple; petals 4, long-clawed; upper calyx-segm. cuspidate. B.M. 6557. G.W. 4, p. 39.

AA. *Lfts. toothed or serrate.*

B. *Calyx gibbous at base.*

màjor, Linn. St. flexuous, glabrous, sometimes 10 ft. or more in height, with a widely creeping root: lvs. gray, a foot or more long, the upper ones smaller; stipules grown together into one large intra-axillary piece, attached to the lower part of the petiole; lfts. 9–11, 3–4 in. long, 2 in. wide: racemes densely fld., 1 ft. or more in length; bracts ovate, acuminate: fls. red-brown, 1 in. long: caps. papery, 4-lobed at the apex, 1–1¼ in. long; seeds 2 in each cell, black and shining. Cape. G.C. III. 36:142. B.R. 45. R.H. 1867, p. 131; 1913, p. 413. G.W. 4, p. 37.—An excellent foliage plant. *M. intermèdius,* Hort., is a hybrid between this species and *M. comosus.*

BB. *Calyx not conspicuously gibbous at base.*

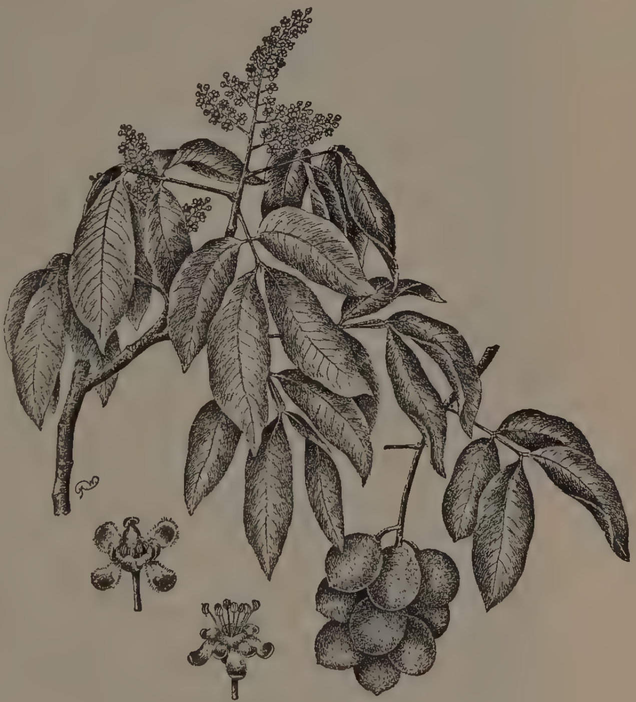
mìnor, Linn. Shrub with branchlets and infl. somewhat canescent: lvs. 5–6 in. long; stipules 2, subulate, lateral free; lfts. 1½–2 in. long, 6–10 lines wide: racemes 6–12 in. long, subterminal; fls. dull red: caps. obtuse at each end, scarcely 4-lobed, 8 lines long.

comòsus, Vahl. Shrub with grayish white branches: lvs. 4–6 in. long; lfts. lanceolate, serrate, pubescent above but becoming glabrate, white-tomentose beneath: fls. orange inside, red-spotted outside and green at base, alternate in nodding racemes; petals oblong or spatulate: caps. oval, 4-winged. B.M. 301 (as *M. minor*).

M. B. Coulston.
L. H. B.†

MÉLICA (old Italian name for Sorghum, from *mel,* honey). *Gramíneæ.* Melic Grass. Slender-stemmed perennials: spikelets 2- to several-fld., rather large, often richly colored or with a pearly luster, in narrow or open panicles.—Species about 35, throughout temperate zones. Several beautiful native species of U. S., but not known in cult. *M. ciliàta,* Linn., of Eu., with a pale spike-like panicle of silky spikelets is sometimes cult. for ornament, and *M. violàcea,* Cav., a Chilean species with graceful panicles of violet-tinged broadly winged spikelets, has been recently intro.

A. S. Hitchcock.



2349. Melicocca bijuga. (Sprays × ¼)

MELICÓCCA (Greek, *honey berry,* referring to the taste of the fruit). *Sapindàceæ.* Two species of tropical fruit trees, natives of America.

Leaves abruptly pinnate: racemes divided; calyx 4-parted; segms. imbricated; petals 4; stamens 8; disk complete; stigma peltate, sub-sessile; ovary 2-celled: berry 1–2-seeded.—S. Amer., perhaps native also in W. Indies.

bíjuga, Linn. Spanish Lime or Genip. Fig. 2349. Lfts. in 2 pairs, elliptical or elliptic-lanceolate, entire, glabrous: fls. whitish, in terminal racemes.—Cult. and naturalized in W. Indies and perhaps native there. The foliage is distinct, the compound lvs. with winged petioles resembling those of *Sapindus saponaria*, the W. Indian soap-berry. The Spanish lime is cult. in S. Fla. and S. Calif. Its frs. are about the size and shape of plums, green or yellow, and have a pleasant grape-like flavor. The large seeds are sometimes roasted like chestnuts. The tree grows slowly, attaining 20–60 ft., and bears freely. It can be fruited in the N. under glass. It withstands several degrees of frost. This fruit is the mamoncillo of Cuba, where it is much prized. It is little known in the U. S. The fr. is usually about an inch long, with thin leathery and green skin and a rather scant acid refreshing pulp that adheres closely to the seeds; it is eaten out of hand, being torn open at one end to allow the translucent white and juicy contents to pass into the mouth. L. H. B.

MELILÒTUS (Greek for *honey lotus*). *Leguminòsæ.* Sweet Clover. Melilot. Perhaps twenty species of annual or biennial tall-growing sweet-smelling herbs, widely distributed in temperate and subtropical regions as weeds, some of them of value for forage and green manure.

Leaves pinnately 3-foliolate, the lfts. toothed and mostly narrow: fls. small, white or yellow, in slender, long-stalked, axillary racemes; calyx-teeth short and nearly equal; corolla papilionaceous, the standard oblong or oblong-obovate, keel obtuse: fr. a small, few-seeded, not twisted but more or less reticulated flattish indehiscent or tardily dehiscent pod.—The species are native in temperate and subtropical regions in the northern hemisphere. Two species, *M. officinàlis*, Lam. (yellow-fld.), and *M. álba*, Desr. (white-fld.), have become weeds along roadsides and in waste places. *M. índica*, All., a common weed in Calif., has very small yellow fls. A recent species.

The prevailing sweet clover, the country over, is *M. alba.* It is an erect biennial herb, often higher than a man, flowering abundantly in spring and early summer. It is said to prefer soils rich in lime, and it thrives on poor and dry soils. Under the name of Bokhara clover and sweet clover, it is grown somewhat as a forage plant. Cattle come to like it for grazing, particularly if turned on it early in the season, before other herbage is attractive. It may also be cut for hay, particularly the second year. About twenty pounds of seed is required to the acre. It is an excellent bee-plant. L. H. B.

MELÌNIS (Greek, *meline*, millet). *Gramíneæ.* A glutinous grass with branched decumbent stems, flat blades and terminal panicles of very small spikelets, of value as a forage plant in the tropics.

Spikelets 1 line long, with a perfect terminal floret and a sterile floret below; first glume very small; second glume and sterile lemma about as long as the spikelet, notched, the latter awned; perfect floret awnless.—Species one.

minutiflòra, Beauv. (*Pánicum Melìnis,* Trin.). Molasses Grass. Two to 4 ft., the base branched, decumbent, tangled and rooting: sheaths and blades viscid-pubescent: panicles purplish, 3–6 in. Brazil and S. Afr. Mart. Fl. Bras. 22:33.—A good forage grass. Has been tested in the W. Indies and in S. Fla.
A. S. Hitchcock.

MELIÓSMA (Greek *meli,* honey, and *osma,* odor; alluding to the fragrant flowers). *Sabiàceæ.* Trees or shrubs grown for their handsome foliage and the large panicles of white or whitish flowers.

Deciduous or evergreen trees or shrubs: lvs. alternate, without stipules, simple or odd-pinnate, with opposite lfts. serrate or entire: fls. in terminal or axillary panicles, perfect, rarely polygamous; sepals 5, rarely 4; petals 5, unequal, the outer 3 roundish, imbricate; the inner 2 much smaller, usually lanceolate, often bifid; stamens 5, usually connate with the petals, the outer 3 sterile; reduced to irregularly cup-shaped staminodes, the inner 2 fertile, the anthers surrounded at the base by the cup-shaped apex of the filaments; ovary superior, often surrounded by a disk, 2-celled, rarely 3-celled, each cell with 2 ovules; style simple: fr. a subglobose or oblong small drupe, usually 1-seeded.—About 50 species in E. and S. Asia and in Cent. and S. Amer.

The meliosmas in cultivation are handsome deciduous trees or shrubs with large pinnate or simple generally oblong leaves with numerous closely set lateral veins, with large often drooping panicles of small white or yellowish usually fragrant flowers followed by pea-sized black or red fruits. Except *M. myriantha,* they are of recent introduction and little is known of their hardiness and their cultural requirements, but they certainly possess promising ornamental qualities, the handsomest being apparently *M. Beaniana* and *M. Veitchiorum.* The latter and *M. cuneifolia* have proved hardy in southern England, and in this country they will probably be hardy as far north as New York or even New England, while the other species are tenderer. Propagation is by seeds sown as soon as they are ripe; also by layers and probably by cuttings of half-ripened wood under glass.

A. *Lvs. simple.*

myriántha, Sieb. & Zucc. Tree, to 30 ft.: lvs. obovate-elliptic to oblong or oblong-obovate, short-acuminate, broadly cuneate or sometimes rounded at the base, toothed, glabrous above, sparingly pubescent beneath, more densely so on the veins, without tufts of hairs in the axils of the veins, 4–8 in. long, with 24–30 pairs of veins: fls. greenish yellow, ⅙in. across, in upright panicles 6–8 in. long, with ascending branches: fr. red, ¼in. across. July. Japan. S.I.F. 2:46. G.C. III. 31:30.

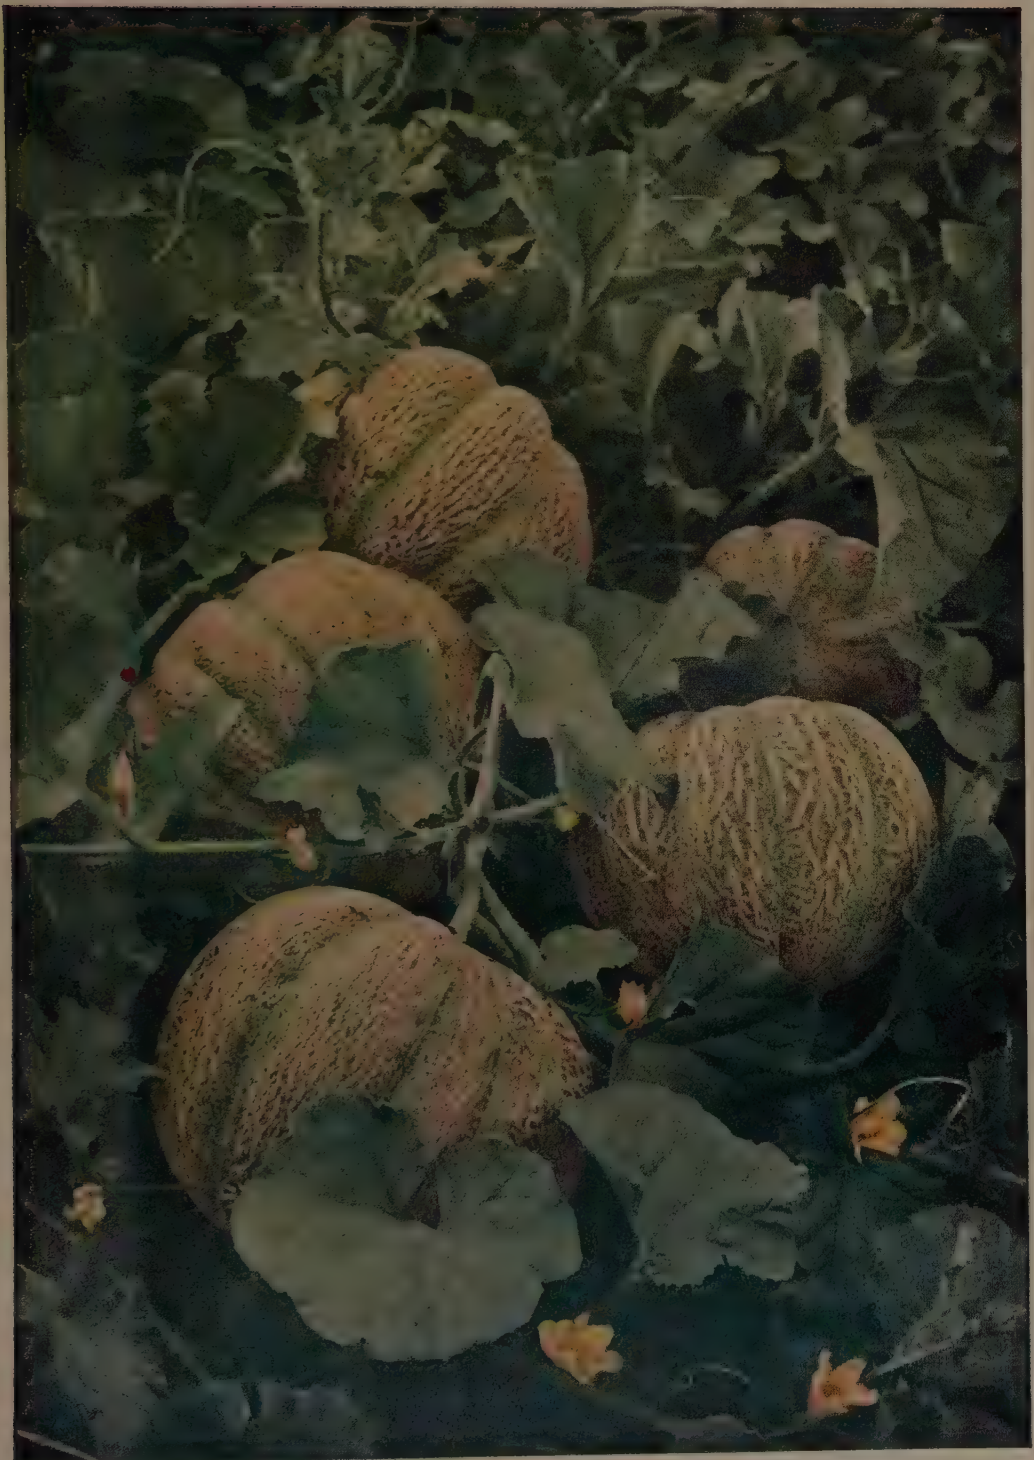
cuneifòlia, Franch. Shrub or tree, to 20 ft.: lvs. obovate, acute or abruptly acuminate, narrowly cuneate at the base, sinuately toothed, glabrous above, pubescent on the veins beneath and with tufts of hairs in their axils, 3–7 in. long, with 20–25 pairs of veins: fls. yellowish white, ¼in. across, in upright panicles with spreading branches, about 8 in. across: fr. black, ¼in. across. July. W. China. B.M. 8357.

AA. *Lvs. odd-pinnate.*

Veitchiòrum, Hemsl. Tree, to 50 ft.: young branchlets with brown shaggy hairs, soon glabrous, marked with conspicuous lenticels and the older ones with large lf.-scars: lvs. 1–3 ft. long; lfts. 9–11, ovate to ovate-oblong or oblong, obtusish or short-acuminate, rounded or broadly cuneate at the base, entire, rarely remotely crenate-serrate, glabrous or nearly so, 3–7 in. long: panicles terminal and axillary, drooping, 8–15 in. long, with or after the lvs.; fls. yellow, ⅕in. across: fr. black, subglobose or pyriform, ¼–⅓in. across, sparingly produced. May: fr. in Sept. Cent. China. —A handsome tree with its large pinnate foliage and the long drooping panicles of very fragrant yellowish fls. A recent species.

Beaniàna, Rehd. & Wilson. Tree, to 50 ft.: young branchlets brownish tomentose: lvs. 6–12 in. long; lfts. 5–13, ovate to elliptic-lanceolate, acuminate, cuneate or sometimes rounded at the base, remotely serrulate or nearly entire, glabrous above and nearly glabrous beneath except tufts of hairs in the axils of the veins, 2–6 in. long: panicles very numerous, before the lvs., 4–8 in. long; fls. creamy white, ⅕in. across: fr. globose, black, ¼in. across. May; fr. in Sept. Cent. China.—A striking plant when covered in spring with a mass of creamy white fls.

M. Oldhamii, Miq. Tree, to 60 ft.: lvs. odd-pinnate; lfts. 9–13, ovate to oblong, serrate, nearly glabrous, 2–4 in. long: fls. white, in broad panicles, 8–12 in. across. Cent. China to Korea.—*M. péndens,* Rehd. & Wilson. Allied to M. myriantha. Shrub, 8–15



LXIX. Muskmelon of the Hackensack type.

ft.: lvs. obovate-elliptic to obovate-oblong, sparingly pubescent beneath, particularly on the veins, 2–5 in. long: panicles slender, drooping, with spreading or reflexed branches; fls. white. Cent. China.

Alfred Rehder.

MELÍSSA (Greek, *bee;* because the bees are fond of balm). *Labiàtæ.* Hardy perennial herbs from Europe and western Asia, one of which is Balm (see Vol. I, p. 442).

Plants erect, leafy and branching, with broad opposite lvs.: fls. white or yellowish, in axillary clusters, somewhat secund; corolla exserted from the long-campanulate calyx, curved, enlarged above and naked within, 2-lipped, the upper lip erect and notched and the lower one spreading and 3-lobed; stamens 4, didynamous, ascending and approximate under the upper lip; style cleft at top: nutlets smooth.—Species 3 or 4, in Medit. region and Cent. Asia.

officinàlis, Linn. Balm. Probably the only species cult., is one of the sweet herbs: pubescent odorous perennial, from S. Eu., N. Afr. and east, sometimes escaped from gardens in this country: lvs. ovate, crenate-dentate: fls. several in each cluster, nearly white or yellowish. Var. **variegàta,** Hort., sometimes used for edgings.

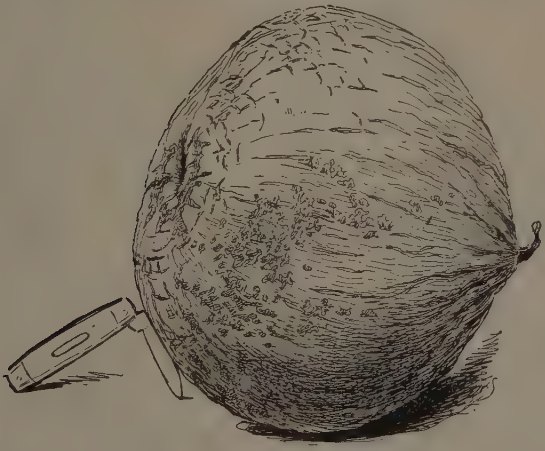
L. H. B.

MELÍTTIS (from Greek *melitta, melissa,* a bee). *Labiàtæ.* One perennial herb in Cent. and S. Eu. and W. Asia, useful for hardy borders. Technically it differs from the long-fld. species of Stachys by its large usually 3-lobed calyx and axillary fls. *M. Melissophýllum,* Linn. (*M. grandiflòra,* Smith), has nearly simple sts. 12–18 in. high, erect, slightly hairy: lvs. cordate-ovate, dentate: fls. large, 2–6 together in axillary whorls, shorter than the lvs., pink and variously variegated; corolla 1–2 in. long, the tube broad, the upper lip erect or reflexed, the lower lip spreading and 3-lobed; stamens 4, in pairs.

L. H. B.

MELOCÁCTUS: *Cactus.*

MELON. A name applied to two very different fruits of the Cucurbitaceæ. Unqualified, the word refers to fruits of the different botanical varieties of *Cucumis Melo* (which see, Vol. II, p. 907). The word muskmelon usually refers to the same fruits, although some forms of *Cucumis Melo* are not musk-scented. The word watermelon refers to the fruits of *Citrullus vulgaris* (Vol. II, p. 780). Inasmuch as the cultural requirements for all melons are very much alike, the whole subject is considered here together.



2350. The Cassaba melon. (×¼)

The cultivated forms of *Cucumis Melo* are very many, and they are difficult of clear classification. The musk-scented forms might be assembled into one group, including the nutmeg or netted melons and the cantaloupe or hard-rinded melons, although the name cantaloupe has become generic in this country for all musk-scented melons. The non-odorous, or at least relatively non-moschatous, melons might comprise another group; and to this would be referred the winter melons, *Cucumis Melo* var. *inodorus.* The winter melons, as a whole, have not been popular in North America, and are, in fact, not generally known. They require a long season in which to mature (see Cornell Bull. No. 96, pp. 364–366, 1895). Very likely the so-called winter or late-keeping melons may not all represent the botanical var. *inodorus.*—Some of the forms of the species are used in the making of preserves and condiments, or even grown for ornament, rather than for eating out of hand. Of such are the Chito (Fig. 2351) and Dudaim types, which are described on page 908.

To the winter melons probably belongs the Cassaba (Fig. 2350), which has lately become popular in California, whence it is shipped east late in the season. The name, variously spelled Kassaba, Cassaba, Casaba, Cassabah, Casba, is derived from the town Kassaba near Smyrna, Asia Minor, whence it was introduced. The seed has been more or less in commerce for many years. According to G.P. Rixford, the seed of the late Kassaba was sent from Smyrna to California late in 1878 by Dr. J. D. B. Stillman and James L. Flood, who found the melons in the hotels of that city. A crop was grown in California in 1879, and appeared on the markets that autumn in limited quantity. M. Rixford, then connected with the "Evening Bulletin," secured a good part of the stock and the next summer had a large quantity raised; and in the winter of 1880–81 seeds were distributed to 3,000 country subscribers of the "Bulletin." The melons did not then become popular, however, because they were usually marketed too green; for these melons must be thoroughly ripe to disclose their excellent flavor. In the original edition of "California Vegetables" (1897), Wickson describes the Cassaba or Pineapple melon as "fine, large, late variety, rich, cream-colored flesh; keeps well into winter."

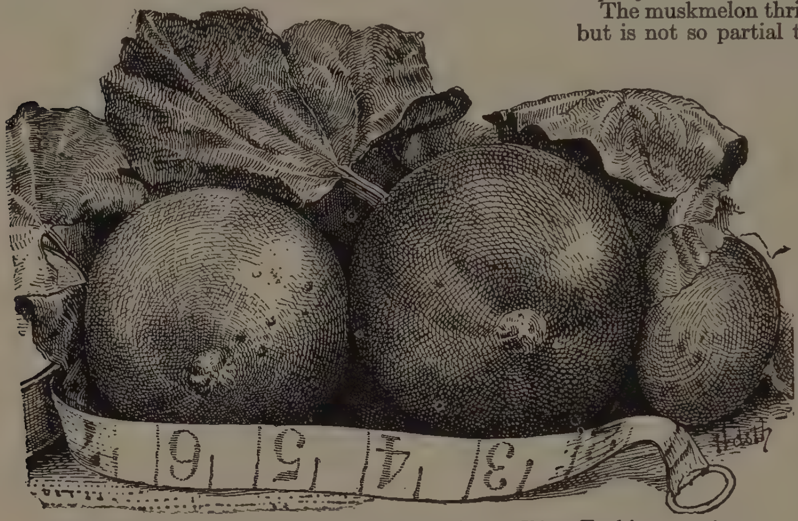
Another Cassaba melon was sent out long before this by the Patent Office, before the organization of the Department of Agriculture. This received special attention from General Bidwell of Chico, California, and became known as the Bidwell Cassaba. This is a large summer melon, said to grow to 1 foot in diameter. This is said to be known only locally, although it was grown at Cornell twenty-five years ago.

On the introduction of Cassabas in this country, W. W. Tracy writes as follows: "The name Cassaba was used in this country as early as 1871, when Bridgman offered the 'Persian,' or 'Ordessa,' or 'Cassaba.' The 'Green Persian,' which seems to have been very much like that stock, if not identical with it, was offered by Ross, of Boston, in 1827. In 1872, Henry A. Dreer offered 'Cassaba' and published a good illustration of it; this seems to be very much like the Bay View of more recent years except that it is more pointed at the stem-end. None of these melons, as they are remembered, was like the Cassaba of California trade today, but were very much like the Cassaba as grown at Chico, California, under the name of Bidwell Cassaba. It seems that the term 'Cassaba' has been used indiscriminately for several different varieties of melons, some of them quite distinct from the others."

L. H. B.

Muskmelon.

The modern cultivated varieties of muskmelon are supposed to have been derived from the wild types native to Asia and Africa. There is some question as to whether the melon was known to the ancient Egyptians as a cultivated plant. It was probably introduced into the Mediterranean countries of Europe about the beginning of the Christian era. Pliny refers to a "new form of cucumber. . . . called *melopepo*, which grows on the ground in a round form, and . . . . although not suspended, yet the fruit separates from the stem at maturity." Nonnius, in the sixth century, speaks of "cucumbers" which are highly odorous. It seems probable that these authors refer to the muskmelon. By the sixteenth century, many varieties of muskmelon were known to European writers.



2351. The Orange or Chito melon.—Cucumis Melo var. Chito. Used in preserving.

The melon reached America among the earliest importations of plants from the Old World, for in 1494 it was recorded as grown by the companions of Columbus. In 1535, "musk melons" were mentioned by a traveler on the St. Lawrence. Melons were reported in New Mexico in 1540, and were abundant in Hayti in 1565. In 1584 they were found in Virginia by Captains Amidos and Barlow. In 1609 they were seen on the Hudson River, and were described as abundant in New England in 1629. In 1806, thirteen kinds were mentioned by M'Mahon as being under culture in America. At the present time, over 400 different variety names are given in American seed catalogues, although the number of important varieties is very much less.

There are two principal classes of muskmelons, the soft-rinded or netted melons, often called nutmeg melons (Fig. 2352), and the hard-rinded or warty melons, known technically as rock melons or cantaloupes. The latter class is grown principally in Europe, often under glass, and is little known in America. The term cantaloupe as used in America is primarily a trade name employed to designate nutmeg melons in general, or, more often, the small type of melon that is shipped in baskets or crates.

The class of muskmelons commonly grown in America may be arbitrarily divided into two groups: large-fruited and small-fruited. This classification is important from a marketing standpoint, since the large-fruited melons are grown principally by market-gardeners, and hauled in bulk to their respective markets, where they are sold by count, though sometimes they are grown as a truck crop and packed in crates to be shipped to the general market. The small-fruited melons are usually packed in crates or baskets, and are very much more extensively handled on the general market than the large-fruited type. The typical small-fruited or "crate" melons weigh about one and one-fourth to one and one-half pounds each; the large-fruited melons weigh anywhere from two to fifteen pounds each.

The flesh of the muskmelon may be either salmon-colored or greenish. The green-fleshed sorts are the more delicately flavored, while the salmon-fleshed varieties are likely to have a more pronounced musky flavor. Formerly, the green-fleshed sorts were preferred on most markets; but in the last few years the demand for salmon-fleshed sorts has been increasing rapidly.

The muskmelon thrives best in a fairly warm climate, but is not so partial to intense summer heat as is the watermelon. It can be grown wherever the summers are sufficiently long to enable it to develop and mature its crop between the frosts of spring and fall. From four to five months are required from the planting of the seed to the end of the harvest. It is considered an exacting crop, and is therefore often omitted from home gardens even in regions where it might readily be grown.

Development of the industry.

Up to 1870, muskmelons were grown principally in private gardens, and it was unusual to see them on the markets. A little later, however, the growing of muskmelons for the New York and other eastern markets was started in Maryland, Delaware, and New Jersey. These melons were principally the Hackensack and Anne Arundel varieties (large-fruited), and the Jenny Lind, a small oblate melon. These melons supplied the market principally from the middle of July till the middle of August. Shipments increased from year to year until in the nineties the New York market sometimes handled from two to three carloads a day at the height of the season.

In 1881 the Netted Gem melon, a small, oval, heavily netted green-fleshed fruit, was first introduced to the public. This variety was destined to revolutionize the melon industry of America. It was tested for a few years, and in 1885 was grown for market in a small way by Wm. S. Ross at Alma, Illinois, and by J. W. Eastwood at Rocky Ford, Colorado. Each planted about one-half acre that year. So far as known, these plantings marked the real beginning of the melon industry in Illinois and in Colorado. Having more melons than his local market could consume, Ross shipped two barrels to Chicago in August, 1885. These were the first melons of this type ever seen on the Chicago market, and were the occasion of considerable amusement on South Water Street when the barrels were opened; the melons seemed ridiculously small as compared with the Hackensack and other melons then on the market. However, after the flavor had been tested, the melons were readily sold and an order received for all that could be furnished. The next year, Ross planted 20 acres, and a few years later, 90 acres. Soon a number of his neighbors began planting, and the industry grew at Alma, until the shipments reached ten to fifteen carloads a day. In 1900, from Alma alone 253 carloads were shipped. In the meantime the industry had spread to other Illinois points, including Anna and Balcom in the extreme southern part of the state. Most of the Illinois melons were shipped in one-third-bushel Climax baskets.

Meanwhile the industry had been developing at Rocky Ford, Colorado, though up to 1894 the shipments had been made entirely by local express, and to

Colorado markets only. That year some of the growers joined together and loaded ventilator cars which were shipped by freight. Up to this time the melons had been shipped in boxes, barrels, and home-made crates,—principally crates made from 12-inch boards and common laths sawed in two. In 1896 the growers were supplied for the first time with regular crates made at a lumber mill. These crates were 12 by 12 by 22¼ inches, inside measure,—practically the same as the home-made crates,—and have ever since been the standard package for Rocky Ford melons. In this year a few cars of melons were shipped as far east as Kansas City and St. Louis.

The Rocky Ford Melon Growers' Association was organized in the fall of 1896 for the purpose of coöperative marketing of Rocky Ford melons; and in 1897, 121 carloads were handled in eastern markets, including Pittsburgh and New York. The melons met with favor and sold at good prices. The next year the membership of the Melon Growers' Association was increased to over 800, and more than 5,000 acres of melons were planted. The yield was heavy, and the markets became glutted with unsalable melons, due partly to poor refrigeration. The outlook was discouraging, and many farmers turned their attention to sugar-beets the next year. However, the melon industry continued, and from 1897 to 1905 inclusive, 5,999 carloads were shipped from the Rocky Ford district, the largest number being in 1904, when 1,182 cars were shipped. Refrigeration was improved, so that the melons carried safely even to Boston, a run of 150 hours.

The success of the Rocky Ford melons on the various markets stimulated the planting of melons of the same type in many other parts of the country, especially in the southern states, and Rocky Ford was looked to as the source of seed. Today the production of melon seed, as well as market melons, is an important industry at Rocky Ford. A number of distinct strains of the Netted Gem type of melon have been developed at Rocky Ford, and the seed is sold under various names, such as Watters' Solid Net, Eden Gem, Netted Rock, Rust-Resistant Rocky Ford, and so on.

The growth of the melon industry of the United States from 1897 to 1905 is indicated by the fact that in 1897 only about 400 carloads of muskmelons were marketed, while in 1905 the shipments amounted to 6,920 carloads.

In 1905, the Imperial Valley of southern California sprang into prominence as a melon-producing region. This valley lies mostly below sea-level, and is situated where the climate is extremely hot. Until 1900 it was known only as a desert. That year work was commenced on a canal system for conducting irrigation water to the valley from the Colorado River, a distance of about 60 miles. In 1905, expert growers from Rocky Ford were secured to organize the melon industry and supervise the growing and packing of the product. One thousand acres were planted that year, and 297 carloads of melons were marketed. Production has increased from year to year, until the Imperial Valley has far outstripped Rocky Ford in the production of melons, and is now recognized as the foremost melon-producing region in the world. The shipments from the Imperial Valley for each year from 1905 to 1914 inclusive were as follows:

Year	Carloads	Year	Carloads
1905	297	1910	1,630
1906	577	1911	2,551
1907	644	1912	2,750
1908	1,911	1913	3,502
1909	1,411	1914	4,446

The hot climate of the Imperial Valley makes early planting possible, and carlot shipments usually begin in May, and continue through June and often a large part of July. These melons, due to pre-cooling and otherwise perfect refrigeration, are shipped safely even to the Atlantic seaboard; and thus all the large markets are fully supplied with melons of uniform grade and quality from four to six weeks earlier than was formerly the case.

Beginning with the California product in May, the markets of the United States are supplied with melons of the Netted Gem or Rocky Ford type continuously until late in October. The states producing these melons in sufficiently large quantities to be mentioned in the general market reports in 1914 were as follows, the states being named in approximately the order in which their products first appeared upon the markets: California, Texas, Florida, Georgia, Illinois, Arizona, Arkansas, Oklahoma, South Carolina, North Carolina, Indiana, Nevada, Maryland, Delaware, Utah, New Mexico, Colorado, Tennessee, Michigan.

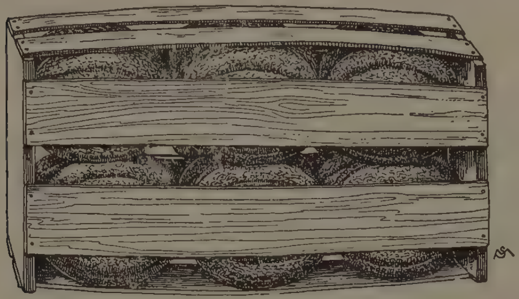
Cultivation of the muskmelon.

Statements that muskmelons demand a particular type of soil are misleading, for the muskmelon can be grown successfully on almost any kind of land from light sandy loam to heavy clay loam, provided the land is properly drained, adequately fertilized, and thoroughly cultivated. Natural drainage is considered best, and melons are usually planted on slopes and knolls rather than on low or flat lands. The soil should be well supplied with humus, either as a result of plowing under a sod or catch-crop or an application of manure. Unless the soil is naturally rich, special fertilizer treatment should be given to the particular spot where each melon hill is to stand. In the home garden, holes are sometimes dug with a spade and partially filled with rotted manure, which is then covered with soil, in which the seed is to be planted. In field culture, the land is furrowed out both ways with a plow, and from a quart to a half-peck of fine, rotted manure or compost is placed at each intersection. The manure is then covered with fine moist soil, and from ten to twelve seeds are planted in each hill. In humid climates, the

2352. A nutmeg melon.

seed is covered about ½ inch deep; in irrigated regions it is covered about 1½ inches.

Attempts to substitute commercial fertilizer for manure in enriching muskmelon hills have usually resulted unsatisfactorily; and attempts to grow melons without special treatment of the individual hills have resulted in failure except on land already very rich, such as market-garden soil or alfalfa sod plowed under.



2353. Crate-or box-packing of melons.

Since muskmelons demand a relatively high temperature and are easily injured by frost, it is useless to plant the seed in the open ground until the weather has become warm and settled. Planting in Colorado, Illinois, Indiana, and similar latitudes usually takes place from May 10 to 20. Attempts to increase the earliness of melons by protection of the plants in the field by means of hand-boxes or forcing-hills are applicable only to amateur areas. Starting the plants in hotbeds and transplanting them to the field when about four weeks old is more practicable on a commercial scale. Since a melon plant is likely to die if the root system is disturbed in transplanting, the seeds must be sown in pots or dirt-bands, or on inverted sods, and the plants very carefully handled during transplanting.

Muskmelon hills are placed from 4 to 6 feet apart, and the plants are thinned to two or three in each hill. Tillage is begun as soon as the plants are visible, and is repeated at frequent intervals until the vines cover the ground, or until the crop is harvested. In the latter case, the vines are kept in windrows, thus allowing space for the pickers as well as permitting late tillage.

In irrigated regions and in rich garden soil, muskmelons are often planted in drills instead of hills. The rows are made 6 or 7 feet apart, and the plants thinned to 2 feet apart in the row. If the crop is to be irrigated, the seed is sown close to the irrigation furrows, and the water turned in immediately after planting, to insure germination. Irrigation is repeated according to the demands of the crop, until the melons are well developed; then the water is withheld to a large extent, and little if any irrigation is given during the picking season. Comparative dryness of the soil when the melons ripen favors the development of high quality in the fruits.

In addition to tillage (and irrigation, in an arid climate), the care of muskmelons consists principally in protecting them from their enemies. Striped cucumber beetles are likely to attack the plants as soon as they appear above ground. They may be controlled by the application of a repellant, such as turpentine mixed with land plaster and dusted on the plants, or bordeaux mixture applied as a spray. The melon louse or aphis is often a serious enemy, especially in dry seasons. It is readily controlled by spraying with nicotine sulfate, if precaution is taken to reach the undersides of the leaves with the spray. The leaf-spot or "rust" is a fungous disease that attacks the foliage of muskmelons, and in some localities has interfered seriously with the production of a marketable crop. In the case of a severe attack it so weakens the vines that the melons do not develop properly and are of poor flavor. This disease has been controlled successfully by repeated spraying with bordeaux mixture, the turning of the vines into windrows making late spraying possible. Also, rust-resistant strains of melons have been developed; so that the disease is no longer a serious menace to the melon industry.

Harvesting and marketing.

Muskmelons must be picked while still firm in order to reach the market in an acceptable condition, yet if they are removed from the vines too early they lack flavor. Unless the market is too distant, melons of the Netted Gem type should not be picked until they will part readily from the stem, and the color of the skin changes slightly from green to gray as seen through the netting. To get the melons picked uniformly at this stage, it is necessary to go over the plantation every day, and in hot weather twice a day.

In order that melons may be kept as cool as possible after they are picked, they are taken immediately to the shade of a packing-shed, where they are graded and packed in crates or baskets. The standard crate for Colorado melons (already mentioned) has been adopted in several other states. It contains forty-five standard-size melons, or twenty-seven to thirty-six "Jumbo" melons. "Pony" crates are slightly smaller (11 by 11 by 22¼ inches), and are packed with fifty-four smaller melons. The melons in the standard crate are arranged in three tiers of fifteen melons each, and each tier is three melons wide and five melons long. Since the crate is made of slats, forty-two of the forty-five melons can be seen from the outside. This permits thorough inspection of the contents of every crate, both at the shipping-point and on the market. Rigid inspection before shipment has helped materially in establishing the reputation of Rocky Ford melons on the markets. California melons and some of the Colorado melons are wrapped in tissue paper to insure better keeping in long-distance shipments. When so handled, the packing is more rigidly supervised, and less dependence is placed on inspection at the loading-platform.

If melons are to be more than twenty-four hours en route, they are usually shipped under refrigeration. The crates are loaded three tiers high, and ample space is left for circulation of cold air. A minimum carload consists of 364 crates, averaging sixty-six pounds each, and the melons seem to reach market in better condition if the cars are not more heavily loaded.

2354. Basket-packing of melons.

The handling of muskmelons or "cantaloupes" in carload lots is an important branch of the produce business, and certain firms known as "general distributors" make a specialty of this product.

Montreal muskmelons; frames.

In addition to the small-fruited "crate" or "basket" melons that are shipped by the carload across the continent, and the ordinary varieties of large-fruited melons that are very generally grown by market-gardeners in outdoor culture, there is a large-fruited variety known as the Montreal Market, which is grown principally near Montreal, Canada, by special methods, and commands very high prices in some of the eastern markets. The seed is sown in greenhouses or hotbeds, usually in pots, early in March, and the plants are later set in sash-covered frames, which afford protection until the crop is nearly grown. Before the frames are placed, the soil is thrown up in ridges about 12 feet wide, and a trench 2 feet wide and 15 to 18 inches deep is dug along the center of the ridge. This trench is filled nearly level with fermenting manure, and then covered with fine moist soil. When the soil over the manure has attained the right temperature, the plants are set. Usually one hill (two plants) of melons are grown under each sash; so that a 6 by 12 frame will accommodate four hills if 3- by 6-foot sash are employed. Great attention is given to watering, syringing, and ventilation. As the fruits develop, they are kept from contact with the soil by means of shingles, pieces of board, flat stones, or slate. Each fruit is turned every few days to insure uniformity in ripening and in development of netting. When the area within the frames becomes fully occupied by vines, the frame is raised a few inches above the ground so that the growing tips of the vines may push out. More ventilation is given as the season advances, and finally the sash and even the frames are removed entirely. The melons thus finish their ripening under outdoor conditions.

Montreal melons are shipped in large wicker baskets, holding one dozen melons each. The melons are packed in fine hay, and the baskets are shipped without covers.

Cassaba melons.

The melons commonly grown in the United States are perishable after reaching maturity, and their market season ends in October. Certain types of muskmelons known as winter melons will keep for several weeks after being picked, if they are properly handled. Melons of this type were formerly little known in America, but are now grown commercially in the San Fernando Valley in southern California, and are shipped by the carload to the larger eastern markets, principally during November and December. The seed was brought from the Mediterranean countries over thirty years ago, and tried in California. The first attempts at growing these melons were not commercially successful, but a few districts were found to be especially adapted to their culture. In the valley above mentioned, hundreds of acres are planted every year. These melons are large, firm, smooth-skinned, and very thick-fleshed. On the market, they are known as Cassaba melons. They are packed in excelsior in half-cases holding six melons, or in full cases holding twelve melons.

JOHN W. LLOYD.

Watermelon.

The watermelon, *Citrullus vulgaris* (Figs. 2355, 2356), is a native of Africa, and is normally a dry-country plant. David Livingstone, writing in 1857, describes it as being very abundant in favorable years in the Kalahari Desert. He says that the species is very variable, some fruits being bitter and some sweet. All the animals of the region from elephants to mice, including the carnivora, seem to enjoy the fruits.

The watermelon was early taken to India, since it has a Sanskrit name. It reached China about the tenth century A. D. It has no name in the ancient Greek and Latin languages, and was probably not known to these people much before the Christian Era.

There are three fairly well-marked types of the cultivated watermelon: the round preserving "citron" (Fig. 2355), the stock (live-stock) melon, and the ordinary watermelon. The two former groups are usually more hardy, more disease-resistant, stronger growers, and more productive. It seems probable that the forms of melon found on our southwestern prairies, and in the cotton fields of the South have returned to approximately their original wild condition. There is apparently little data on the original introduction of the watermelon into the United States. Judging from the varieties at present extant, it does not seem likely that it reached us from Mediterranean lands.

2355. The preserving watermelon, commonly known as "citron."

Commercial importance.

The watermelon is the most valuable vine crop grown in the United States. As a garden plant it has a wide distribution, but as a commercial product its culture is confined chiefly to the region to which the long-leaf pine is indigenous. This region includes the states bordering the Atlantic from Virginia southward as well as those bordering the gulf. The only states outside this territory which grow watermelons on a commercial scale are New Jersey, Indiana, Illinois, Oklahoma, Kansas, and California. The six states producing the bulk of the commercial crop in the order of their importance are Texas, Georgia, Florida, Indiana, Mississippi, and California.

The value of the commercial crop of watermelons in the United States, as stated by the census of 1910, was nearly $4,500,000, grown on 137,000 acres.

In comparison with other vegetable crops, the watermelon stands seventh. The crops having a greater value are Irish potatoes, sweet potatoes, tomatoes, cabbage, onions, and sweet corn, in the order named.

Cultivation.

The watermelon thrives best on light, warm, sandy soils well supplied with organic matter. The plants require a liberal moisture supply during their early life, but are able to produce abundantly in regions with relatively spare rainfall. In order to develop superior quality, the temperature during the fruit-bearing period should be high.

The preparatory treatment of the soil for watermelons preferred by most growers is to turn under a crop of cowpeas the previous autumn. An area which has not been under cultivation for several seasons and upon which there is a good stand of broom-sedge or grass is the second choice. While watermelon seed does not require to be planted early, the land should be prepared in time to allow weed seeds to germinate so that at least the early weed crop can be destroyed by harrowing before the melon seed is planted. This is important as the crop can be given thorough culture only previous to the vining of the plants. The object should be to do most of the cultivation before the crop is planted.

The watermelon, like all other vine plants, is a gross feeder and requires an abundant supply of available plant-food over a comparatively short growing season. For this reason, the fertilizing should be liberal and the materials used of a nature to be quickly available. When stable manure can be secured, this is to be preferred, but when it is not to be had crops planted on lands which have had a crop of cowpeas turned under respond reasonably well when a fertilizer carrying 3 to 4 per cent of nitrogen in the form of nitrate or sulfate of ammonia, 8 per cent of potash, either sulfate or muriate, and 8 per cent of phosphoric acid, either superphosphate or high-grade acid phosphate, is used at the rate of 400 to 500 pounds to the acre in the drill.

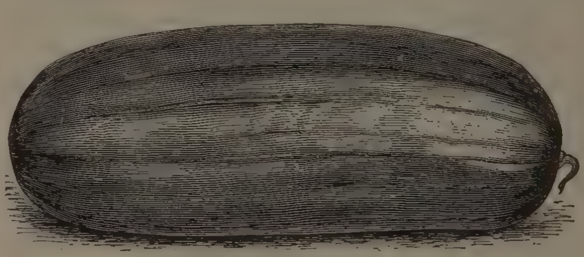
There is no advantage to be gained from planting the seed for the commercial crop of watermelons before the soil is in thorough tilth and well warmed up. Planting should be delayed until both the soil and the season are warm enough to insure quick germination of the seed and rapid growth of the plants. As a rule, the period for planting watermelons follows within a fortnight that for corn.

The watermelon is a more robust plant than either the cucumber or the muskmelon and requires more liberal spaces between both rows and hills in the row. Two general systems of planting are followed: planting in rows and planting in hills. Row-planting is very generally practised in some localities; the method followed is to open a furrow in which the fertilizer or manure is scattered and incorporated with the soil by the use of a suitable implement such as a scooter or sweep. Two furrows are then turned together over the fertilizer to form the bed on which to plant the seed. In humid sections this is somewhat above the general level of the surface, but in dry regions the seed is either planted on the level or slightly below. An abundance of seed is used so as to insure a dense stand of plants in order to fortify the plantation against the ravages of insect pests. After the plants are well established and the danger of loss of stand from insect depredations is over, the rows are thinned so that individual plants stand at intervals of 2 or 3 feet, or they may be thinned so that groups of three or four plants are as far as 6 or 8 feet apart. The rows are usually 8 feet apart. In the hill system of planting, the fertilizer is put either down the length of the row as above described, or the land may be laid off in check-rows 8 by 8 feet apart and a shovelful of well-rotted stable compost placed under each hill located at the intersection of the 8-foot marks. Fertilizer may be used instead of the manure. A stand of plants is insured by placing a dozen or more seeds in a hill, the seeds being scattered over an area of about 1 square foot and the seeds covered with not more than 1 inch of earth.

As has been observed, the main cultivation of the watermelon crop should be made before the seed is planted. No opportunity, however, should be lost to keep the land free from weeds and in a fine state of tilth from the time the plants appear above ground until the vines are too large to continue the use of horse-power implements. Even after implements are excluded, all large weeds should be pulled by hand. In many sections of the South, it is a common practice to sow a light seeding of cowpeas in the watermelon fields at the time of the last cultivation to act as a partial shade to the fruits and to prevent the whipping of the vines in the wind. The cowpeas also contribute to the upkeep of the land, an important factor with the light soils used for melon-culture.

Melons should not follow closely after melons on the same land, as areas used too frequently for melon-culture are almost certain to become contaminated with the wilt disease fungus. As this fungus is capable of perpetuating itself for considerable periods when once the soil is infested, a rotation period of five to seven years is desirable in order to avoid losses on lands which have been previously used for the crop.

As has been suggested, the watermelon is not immune to the ravages of insect pests and fungous diseases. The striped cucumber beetle is one of the most annoying and destructive insect pests attacking this crop. In the garden it can be controlled most satisfactorily by the use of screens or by a square of mosquito netting dropped over a tiny stake in the center of the hill in such a manner as to form a tent over the young plant; then by drawing earth over the edges of the netting it will be held in place and the insects excluded. The use of tobacco dust or tobacco fertilizer as a mulch for the young plants serves as a fairly effective repellant and is at the same time a valuable fertilizer.



2356. A market watermelon.

The wilt disease has caused great loss in years past and while no effective remedy is known, satisfactory crops can be secured by careful attention to crop-rotation in which wilt-resistant crops form a large factor and in which the interval between melon crops is sufficiently long, five to seven years being none too much.

Harvesting and marketing.

An important consideration in harvesting melons for carload shipment is to avoid mixing sizes in the car. If two sizes are to be shipped in the same car, they should be loaded in separate ends. Buyers establish the price for a load of melons by the minimum size of the melons in the load. Melon markets have strong likes and dislikes. Some prefer melons of a definite size only, others prefer melons with particular markings, while still others require either a long or globular melon. These peculiarities of the market should be carefully studied and the plantings be so planned as to meet the preferences of the market to the fullest possible extent. At shipping-time these features should be kept in mind and the distribution of the melons made accordingly.

Varieties of watermelon.

Melons of the highest quality have brittle flesh, few fibers, and a thin rind. Such melons are not well adapted for shipment but are ideal for home use. The commercial melon is one that has good shipping quality, a firm not too thin rind, of a variety in which the melons run uniform in size, and of a weight ranging from twenty to thirty pounds. The variety must also be productive, of fair quality, and medium early. A few sorts worthy of a place in the garden for home use are McIver, Florida Favorite, Kleckley Sweets, Bradford, Long White Icing, and Sugar Loaf. Those most popular as shipping melons are Kolb Gem, Duke Jones, Pride of Georgia, or Jones, Mammoth Ironclad, and Dixie.

Seed-production.

The production of seed has been largely confined to the new prairie breakings of western Kansas and Oklahoma, where a crop can be grown very cheaply. It is interesting to note that the wild animals, notably coyotes, often destroy a planting, so that few fruits are left for seed. The melons grown for seed are pulped in machines devised for the purpose. These machines separate the rind and pulp from the seeds and juice. The mass of seeds and juice is allowed to ferment for one or a few days, when the seed is washed and spread on wire screens for drying. When the seed is thoroughly dry it should be run through a fanning-mill to drive off melon fragments and light seed, when it is ready for market. A crop of seed is rarely planted by a farmer without a contract with a seedsman, who agrees to take all or part of the crop at a stipulated price.

In practically all sections of the Unites States where field corn can be successfully grown, the watermelon can be depended upon to mature a crop sufficient to justify including it in the home-garden. While it can be grown on a wide variety of soils by giving them special preparation, it nevertheless grows best on rich sandy, or loamy soils. The prairie soils of the corn-belt as well as the glacial-drift soils of New York can be successfully used for the garden culture of the crop.

The watermelon is tender to frost, and as it makes its most rapid growth during the warm season, it should not be planted in cold soil or before the danger of frosts has passed. A safe rule for most sections is to plant ten days to two weeks later than corn.

The few hills of watermelons necessary to supply the needs of the average family should be prepared with special care. The seed-bed should be deep and the hills fertilized with manure or compost which will tend to accelerate the growth of the plants. No better use of hog- or chicken-manure can be made than in the preparation of a compost for watermelons. The hills should be given ample distance—7 or 8 feet each way—and the seeds should be scattered ten or twelve over an area about 1 foot square, and covered with about 1 inch of soil.

The young plants will require protection from insects; the use of mosquito-netting, before noted, will prove as inexpensive and as effective as any method yet devised.

After all danger of losing the stand of plants, either by frost or pests, has passed, the population of each hill should be reduced to three or four of the most vigorous plants. From this period on, care to prevent weed-growth should give satisfactory results providing a sort adapted to the region and to home use has been chosen.

L. C. CORBETT.

MELON, Papaw: *Carica Papaya.* **M. Shrub:** *Solanum muricatum.* **Chinese Preserving M.:** *Benincasa.*

MELÒTHRIA (probably a name for a bryony-like plant; *melon* is Greek for apple, which may refer to the shape of the fruit). *Cucurbitàceæ.* Slender herbaceous vines, climbing or trailing, annual or perennial, with small yellow or white flowers and sometimes attractive little fruits, found in warmer parts of the world.

Plants with simple tendrils at the axils and very small monœcious, diœcious or polygamous fls., the sterile usually in corymbs or racemes, the fertile solitary and often slender-stalked: lvs. entire, lobed or divided: fls. white or yellow; sepals 5; corolla 5-lobed, campanulate; stamens in sterile fls. 3 or 5, more or less connate by the anthers, in the fertile fls. reduced to rudiments: fr. a small pulpy pendulous berry, with usually many flat horizontal seeds.—Species perhaps 70, widely distributed, a few of them native from Pa. and Fla. to Texas.

Four kinds appear to be in the trade, *M. scabra, M. japonica, M. maderaspatana* and *M. punctata,* the last being perhaps the best. These are slender but rapid-growing half-hardy annual climbers, which may be grown indoors in winter, but preferably outdoors in summer for covering unsightly objects. They are attractive in fruit.

Cogniaux (in DC. Mon. Phan., Vol. 3, 1881) makes three sections of the genus. *M. scabra, M. pendula,* and *M. japonica,* belong to the first, *M. punctata* to the second, and *M. maderaspatana* to the third. *M. punctata* has sensitive tendrils.

Section I. EUMELOTHRIA. Fls. usually monœcious, males mostly racemose and females solitary; anthers subsessile: fr. mostly with long and slender peduncles; seeds usually not margined and smooth.

Section II. SOLENA. Fls. mostly diœcious, males corymbose; anthers borne on rather long filaments, the connective not produced: fr. mostly short-peduncled; seeds mostly margined and smooth.

Section III. MUKIA. Fls. monœcious, males clustered and females solitary; anthers subsessile, the connective apiculate: fr. subsessile; seeds margined, usually pitted.

scàbra, Naudin. Sts. more or less hairy: lvs. rigid, ovate-oblong or somewhat triangular-hastate, acute or short-acuminate, scabrous: tendrils filiform, short: fls. small, the masculine racemes 5–7-fld. and equaling the petiole; anthers roundish, with a wide connective, the cells straight, not plicate: fr. ovoid or ovoid-oblong, obtuse, 3-celled, rather large (1 in. long, ½in. thick), with broad parallel stripes of white and green. Mex. R.H. 1901, p. 43.

péndula, Linn. Creeping or scandent, much-branched root-perennial, the st. glabrous and shining: lvs. suborbicular-cordate, acute or obtuse, hirsute becoming scabrous, often deeply 5-lobed, the lobes obtuse: male racemes 3–7-fld., usually shorter than the petioles; corolla yellow, the segms. obovate: fr. ellipsoid, to ½in. long, the seeds obovate and whitish. Pa. to Fla. and La. and Mex.—*M. pendula, M. scabra* and *M. punctata* may be confused in horticultural literature.

japónica, Maxim. Lvs. ovate-triangular, emarginate at base, scabrous above, nearly smooth beneath, entire or shallowly 3-lobed: male fls. solitary; anthers suborbicular, not appendaged at apex: fr. ovoid-subglobose, the seeds usually marginless. Japan.

punctàta, Cogn. (*Bryònia punctàta,* Thunb. *Zehnèria scàbra,* Sond. *Pilógyne suàvis,* Schrad.). Sts. glabrous at maturity, angled: lvs. membranous, cordate, angled or slightly 3–5-lobed, white-spotted and somewhat scabrous above, pilose, short-hairy or scabrous below, margin remotely denticulate: fr. brown, lightly pitted, about 3 lines thick; seeds small, about 2 lines long, strongly compressed. S. Afr. R.H. 1900, p. 661.—Intro. 1890 by Henderson & Co. as the oak-leaved climber. *Melothria punctata* is a beautiful climbing herbaceous perennial, better known as *Pilogyne suavis,* and sometimes called *Zehneria suavis.* Even when protected, it is too tender to stand the northern winters. It blooms in clusters; fls. small, white and star-shaped, with a strong musk fragrance: lvs. green, small and glossy. Being a very rapid grower, it is desirable for covering verandas or for house cult. It will do well in any part of a living-room where it has light. It will grow as much as 16 ft. high in one summer by having a liberal supply of water every day and liquid manure once a week. After growing outdoors it can be cut down to 6 in., potted and taken into the house for the winter. In the spring it can be cut back, again planted out and it will do well. The roots may almost be called tuberous, and can be kept dormant in winter, the same as dahlias, buried in sand in a cool, dry place, free from frost. Increased by cuttings. (James Vick.)

maderaspatàna, Cogn. (*Cùcumis maderaspatànus*, Linn. *Bryònia scabrélla*, Linn. f. *Mùkia scabrélla*, Arn.). Annual: lvs. ovate or somewhat deltoid, entire, angled or 3–5-lobed, very scabrous above and scabrous or short-hairy beneath: male fls. fascicled, the female solitary or only partially fascicled: fr. small, globose, smooth or sparsely echinulate, at first green and longitudinally variegated with brown-yellow, becoming red; seeds pitted. Trop. Asia and Afr.

M. fluminénsis, Gardn., produces a fr. said to be pickled when green, in Porto Rico, and eaten, and also good when fully ripe: a climber 5 or 6 ft. long: lvs. cordate-ovate, usually acute or short-acuminate, 5-angled or lightly 3–5-lobed, scabrous above: fr. small, not variegated or otherwise marked and in this differing from M. scabra. Trop. Amer: variable.

WILHELM MILLER.
L. H. B.†

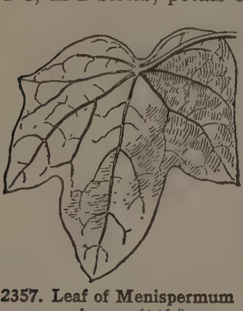
MENÍSCIUM (Greek, *a crescent;* referring to the shape of the sori). *Polypodiàceæ.* A genus of about 10 tropical species allied to Dryopteris, usually with pinnate lvs. and with the main veins united by successive transverse arches, on which the naked sori are borne. They are warmhouse and greenhouse species. See p. 1215.

reticulàtum, Swartz. Stalks 1–3 ft. long, stout: lvs. 2–4 ft. long, 1 ft. or more wide, pinnate; pinnæ 1–4 in. wide, with an acuminate apex, naked or slightly pubescent; main veins 1–1½ lines apart, with 8–12 transverse arches. Mex. and W. Indies to Brazil.

L. M. UNDERWOOD.

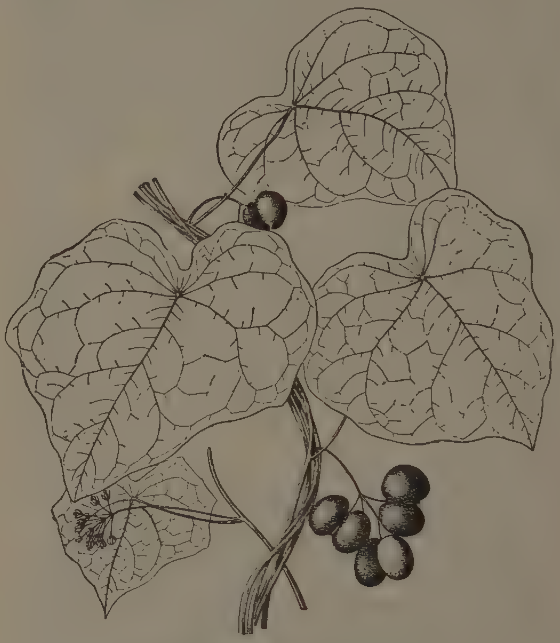
MENISPÉRMUM (Greek, *moonseed*). *Menispermàceæ.* MOONSEED. Hardy and attractive semi-woody climbers.

Twining glabrous or slightly pubescent vines, with alternate long-petioled lvs., which are peltate near the margin, and axillary or super-axillary panicles or cymes of small diœcious not showy fls.: fr. a berry-like drupe, containing a flattened crescent-shaped or curved stone (whence the name moonseed): stamens 9–24, with 4-loculed anthers in the staminate fls., 6 and sterile in the pistillate fls.; pistils 2–4, with broad stigmas; sepals 4–8, in 2 series; petals 6–8, shorter than the sepals.—As conceived by the early botanists, Menispermum contained many species which are now referred to Cocculus, Abuta, Cissampelos, Tinospora, Anamirta and other genera. The genus is now considered to be bitypic, one species in N. Amer. and the other in Siberia, China and Japan. (Diels, in Engler's Pflanzenreich, hft. 46, 1910.) Both the moonseeds are neat and interesting vines, and are hardy in the northern states and Ont. Prop. readily by seeds; or plants of *M. canadense* may be dug from the wild. Cuttings of ripened wood may also be used.



2357. Leaf of Menispermum canadense. (×⅓)

canadénse, Linn. COMMON MOONSEED. Fig. 2357. Sts. slender and terete, woody below, flocculent-pubescent when young, but becoming glabrous, twining 10 ft. or more high: lvs. variable in shape, round-ovate to ovate-cordate, sometimes entire, but usually angulate-lobed, the long petiole attached just inside the margin: fls. greenish white, in loose straggling panicles, the sepals and petals usually 6, the stamens in the male fls. 10–20: fr. bluish black, ¼in. diam., resembling small grapes. Rich soils in thickets and lowlands, Que. to Manitoba and south to Ga. and Ark. B.M. 1910. G.M. 57:153. G.W. 1, p. 63, F.E. 22:493; 28:261.



2358. Menispermum dauricum. (×½)

daùricum, DC. Fig. 2358. In habit much like the above but more vigorous: glabrous: lvs. smaller, distinctly peltate, deeper green, cordate and angular: fls. in cymes, yellowish, the terminal ones with 6 sepals, 9 or 10 petals and about 20 stamens, the lateral ones with 4 sepals, 6 petals and about 12 stamens. S. E. Siberia, Korea, China, Japan. G.F. 5:233 (adapted in Fig. 2358).—Variable. Rarely planted in this country.

L. H. B.

MÉNTHA (from the Greek name of the nymph Minthe). *Labiàtæ.* MINT. Strong-scented perennial herbs; grown mostly for their essential oils but sometimes for ornament.

The term mint, often applied to various species of Labiatæ, is most frequently used to designate plants of the genus Mentha. This genus is characterized by its square sts. and opposite simple lvs. in common with others of the family, and especially by its aromatic fragrance, its small purple, pink or white fls., with mostly regular 10-nerved calyx, slightly irregular 4-cleft corolla and 4 anther-bearing stamens, crowded in axillary whorls and the whorls often in terminal spikes; ovary 4-parted, style 2-cleft: nutlets ovoid and smooth.—Many forms have been described, and the synonymy is extensive. About 30 species are now recognized, all native in the North Temperate Zone, about half of them being native or naturalized in N. Amer. Six species are cult. more or less for the production of aromatic essential oil, which is found in all parts of the herb, and especially in minute globules on the surface of the lvs. and calyx. Some of the species hybridize freely, producing innumerable intergrading forms which make the limitation of certain species difficult.

The mints are scarcely horticultural subjects, although *M. rotundifolia* and *M. Pulegium,* as well as the little *M. Requienii,* may be used as border plants or ground-covers and for the ornamental foliage of some of the forms. They propagate readily by cuttings and division; some of them produce stolons.

INDEX.

arvensis, 8.
canadensis, 6.
citrata, 3.
gibraltarica, 7.
officinalis, 2.
piperascens, 8.
piperita, 2.
Pulegium, 7.
Requienii, 1.
rotundifolia, 5.
spicata, 4.
variegata, 5.
viridis, 4.
vulgaris, 2.

A. *Plant a miniature creeper.*

1. **Requiènii,** Benth. A minute creeping herb from Corsica, used as a carpeter: sts. filiform, ascending: lvs. small, stalked, orbicular: fls. mauve or pale purple in loose few-fld. whorls: plant peppermint-scented.

AA. *Plant larger, erect or tall, or in forms of some species perhaps compact.*

B. *Whorls of fls. in terminal spikes or some in the upper axils.*

C. *Spikes thick: lvs. petioled.*

D. *Lvs. lanceolate, acute.*

2. **piperìta,** Linn. Peppermint. Perennial by runners and rootstocks: sts. erect or ascending, 1–3 ft. high, branched, glabrous: lvs. lanceolate, acute, sharply serrate, 1–3 in. long, glabrous or pubescent on the veins beneath, punctate, with minute oil globules: fls. in thick, terminal spikes, 1–3 in. long in fr., the central spike finally exceeded by the lateral ones; calyx glabrous below, its sharp teeth usually ciliate; corolla purple, rarely white, glabrous. Eu.—Intro. into cult. from England and sometimes naturalized in moist ground. Known as "American mint" or "state mint" in N. Y.

Var. **officinàlis,** Sole. White Mint. Slender, 1–2 ft. high: lvs. 1–2 in. long: sts. and foliage light-colored. Not known in wild state; long cult. in England and sparingly intro. into cult. in Amer.

Var. **vulgàris,** Sole. Black Mint. Rather stout, 2–3 ft. high: lvs. 2–3½ in. long: sts. usually purple and foliage dark-colored. Native in England.—Cult. in recent years in England, Saxony and Amer.

DD. *Lvs. ovate or subcordate.*

3. **citràta,** Ehrh. Bergamot Mint. Perennial by leafy stolons, glabrous throughout: st. decumbent, 1–2 ft. long, branched: lvs. thin, broadly ovate and obtuse or the uppermost lanceolate and acute: fls. in the uppermost axils and in short, dense, terminal spikes; calyx glabrous, with subulate teeth; corolla glabrous. Sparingly naturalized from Eu. in N. Y., N. J., Fla. and Ohio.—The fragrant lemon-scented oil is distilled for use in making perfumes.

CC. *Spikes slender, interrupted: lvs. sessile or nearly so.*

D. *Plant glabrous: lvs. lanceolate.*

4. **spicàta,** Linn. (*M. viridis,* Linn.). Spearmint. Fig. 2359. Perennial by leafy stolons: st. erect, with ascending branches 1–2 ft. high: lvs. lanceolate, sharply serrate, 2½ in. or less in length: whorls of fls. in narrow, interrupted spikes 2–4 in. long, the central spike exceeding the lateral ones; calyx-teeth hirsute or glabrate. Widely naturalized about old gardens throughout the older settled parts of the U. S.; native in Eu. and Asia.

DD. *Plant pubescent: lvs. elliptic or ovate-oblong.*

5. **rotundifòlia,** Huds. Round-leaved Mint. Perennial by leafy stolons, pubescent throughout, somewhat viscid: sts. slender, erect or ascending, simple or branched, 20–30 in. high: lvs. subcordate at base, mostly obtuse, crenate-serrate, 1–2 in. long and about two-thirds as wide, reticulated beneath: fls. in dense or interrupted spikes 2–4 in. long; calyx pubescent; corolla puberulent. Naturalized from Eu., in moist waste places from Maine to New Mex.—Sometimes used as a substitute for peppermint or spearmint. Var. **variegàta,** Hort., with variegated lvs., is used in low borders.

BB. *Whorls of fls. all axillary.*

C. *Plants usually decumbent or prostrate at base: fls. nearly sessile.*

6. **canadénsis,** Linn. American Wild Mint. Perennial by runners and rootstocks: st. usually pubescent, with spreading hairs, erect or ascending, simple or branched, 6–30 in. high: lvs. ovate-oblong or lanceolate, glabrous or nearly so, 2–3 in. long, slender-petioled, the petioles often exceeding the nearly sessile whorls of light purple fls.: calyx pubescent. In wet soil or in water at the margins of streams. New Bruns. to Brit. Col. and southward to Va. and New Mex.—Often called peppermint, for which it is frequently mistaken and for which it is sometimes used as a substitute. It is variable in habit and also in the character of its oil.

7. **Pulègium,** Linn. Pennyroyal. Prostrate, much branched: lvs. small, about ½in. or less long, round-oval, entire or slightly crenate, hairy: fls. in dense axillary whorls, small, bluish lilac; mouth of calyx closed by hairs; upper lobe of corolla notched. In wet places, Eu. and W. Asia, and intro. elsewhere. Var. **gibraltárica,** Hort., is a dwarf compact form with deep green foliage which is sometimes variegated, used in rock-gardens and also in geometrical designs.—*M. Pulegium* has a strong and agreeable odor; lvs. sometimes used for seasoning. It is sometimes grown in kitchen-gardens, preferring a moist rather stiff soil. Prop. by division. The American pennyroyal is *Hedeoma pulegioides.* The oil of the two is similar.

2359. Mentha spicata—Spearmint. (×⅓)

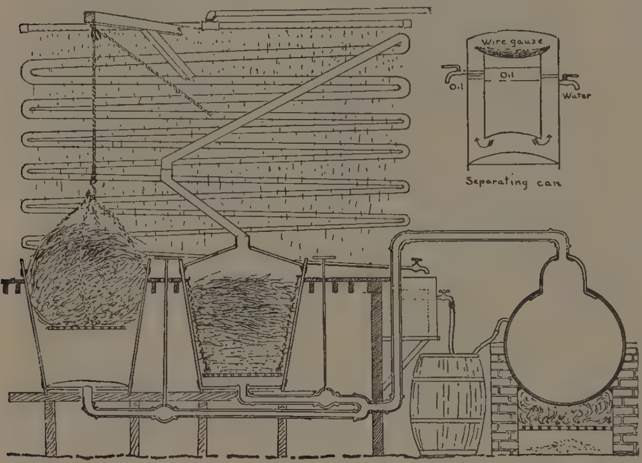
CC. *Plants somewhat rigidly erect: fls. distinctly pedicelled.*

8. **arvénsis** var. **piperáscens,** Malinvaud. Japanese Mint. Perennial by running rootstocks, puberulent or finely pubescent throughout: sts. erect, with numerous branches, 2–3 ft. high: lvs. lanceolate and acute to broadly oblong and obtuse, narrowed at the base, 1½–3½ in. long, sharply serrate, with low teeth: fls. in rather loose, axillary whorls, in distinctly pedicellate umbels, usually shorter than the slender petioles; calyx pubescent, its subulate teeth about half as long as the tube; corolla puberulent. This cult. variety is larger than *M. arvensis* itself, with larger lvs., and yields more oil. The species, *M. arvénsis,* Linn., is naturalized widely from Eu.

Culture of mints for oil.

Peppermint, the most prominent economic species of mint, ranks as one of the most important of all plants in the production of essential oils. It was originally native in Great Britain and possibly in continental Europe, but is now widely naturalized, growing in many places on both continents like a native plant. There is no record of it in America previous to its introduction to Connecticut in the early part of the eighteenth century. From there it was taken to western New York and to the Western Reserve in Ohio, and in 1835 "roots" were taken from Ohio to Pigeon Prairie, in Michigan, where the industry has grown to larger proportions than anywhere else. Peppermint is now cultivated commercially in southwestern Michigan and adjacent parts of northern Indiana, Wayne county, New York, and in Mitcham, Surrey and Lincolnshire, England, and in Saxony.

Peppermint plants may be grown on any land that will produce good crops of corn, but its cultivation is most profitable on muck soils of reclaimed swamps. It is an exhaustive crop, and on uplands is rarely included in the rotation more often than once in five years. On deep, rich muck soils it is often grown consecutively 6 years or more with no apparent diminution in yield. Peppermint is propagated by pieces of running rootstocks, commonly called "roots." These are planted, as early in spring as the ground can be prepared, in furrows 30 inches apart. On uplands two or three crops are usually grown from one setting of the "roots," but in the swamp lands the runners are plowed under after harvest, continuing the crop indefinitely. Clean cultivation is required between the rows, and often it is necessary to hoe the plants or pull weeds by hand, especially on land that has not been well prepared. Fireweed, horseweed, ragweed and other species with bitter or aromatic properties are very injurious to the oil if cut and distilled with the peppermint.



2360. A mint still.

The crop is cut either with scythe or mowing-machine in August or early September, when the earliest flowers are developed and before the leaves have fallen. In long, favorable seasons a second crop is sometimes harvested early in November. After cutting, the plants are cured like hay, then raked into windrows and taken to the stills, where the oil is extracted by distillation with steam. A "mint still" (Fig. 2360) usually consists of two retorts (used alternately), wooden or galvanized iron tubs about 7 feet deep and 6 feet in diameter at the top, each with a perforated false bottom and a tight-fitting, removable cover, a condenser of nearly 200 feet of block-tin pipe immersed in tanks of cold water, or more frequently arranged in perpendicular tiers over which cold water runs, a boiler to furnish steam and a receiver or tin can with compartments in which the oil separates by gravity. The yield of oil varies from ten to sixty pounds to the acre, averaging about twenty-five pounds for black mint, the variety now generally grown. Three kinds of peppermint are recognized: (1) American mint, "state mint" of New York (*M. piperita*), long cultivated in this country and occasionally naturalized; (2) black mint, or black mitcham (*M. piperita* var. *vulgaris*), a more productive variety introduced from England about 1889, and (3) white mint, or white mitcham (*M. piperita* var. *officinalis*), less productive and too tender for profitable cultivation, but yielding a very superior grade of oil. Peppermint oil is used in confectionery, very extensively in medicines, and for the production of menthol, or more properly pipmenthol. Pipmenthol differs in physical properties from menthol derived from Japanese mint.

Japanese mint, secured from *M. arvensis* var. *piperascens*, is cultivated in northern Japan, chiefly on the island of Hondo; not known in the wild state. It has been introduced experimentally in cultivation in England and the United States, but has not been cultivated commercially in these countries. Its oil is inferior in quality to that of *Mentha piperita*, but it contains a higher percentage of crystallizable menthol, of which it was the original source and for the production of which it is largely used. It is propagated by rootstocks carefully transplanted and cultivated by hand-labor. Two crops, rarely three, are obtained in a season, and by abundant fertilizing and intensive culture large yields are obtained. It is usually continued three years from one planting, and then a rotation of other crops follow for three to six years. Three horticultural varieties are recognized, being distinguished chiefly by form of leaf and color of stem. The variety known as "Akakuki," with reddish purple stem and broad, obtuse leaves, is regarded as best.

Spearmint is cultivated on peppermint farms for the production of oil. The plants are propagated and cultivated similar to peppermint and distilled in the same stills. The oil, for which there is a smaller demand than for peppermint, is used chiefly in medicine and to some extent as a flavoring ingredient in chewing-gum and drinks. Spearmint is cultivated in the vicinity of many large cities to supply saloons, where freshly cut sprigs of the plant are used in making the seductive and intoxicating drink known as "mint julep." The plant is more widely known as an ingredient in "mint sauce," the familiar accompaniment of spring lamb and green peas. To supply this demand it is often cultivated in the kitchen-garden. It is easily propagated by the perennial rootstocks, and persists year after year with little care, thriving in nearly all kinds of soil, providing it does not become too dry.

Lyster H. Dewey.
L. H. B.†

MENTZÈLIA (Christian Mentzel, 1622–1701, German botanist). *Loasàceæ.* Showy-flowered plants, some of the herbaceous kinds grown as flower-garden subjects.

Herbs annual and perennial, shrubs and even small trees, glabrous or setose, the sts. often becoming white and shining: lvs. usually alternate, mostly coarsely toothed or pinnatifid: fls. solitary or in racemes or cymes, white, yellowish, yellow or red; petals 5, regularly spreading, convolute in the bud, deciduous; stamens indefinite, rarely few, inserted with the petals on the throat of the calyx: seeds flat, in a caps. dehiscent at the summit.—Species probably 60–70 in the Americas. A good number are native in the U. S. They thrive in sunny moist or dry situations sheltered from strong winds. *M. Lindleyi*, from Calif., is frequent in eastern gardens, where it is commonly known as *Bartonia aurea;* the other species are offered by western dealers, but are not generally in cult. They flower in summer. Although interesting and showy, these plants have not become popular with gardeners. The seeds should be sown where the plants are to remain, as they do not bear transplanting. *M. bartonioides*, Benth & Hook., is Eucnide (which see); *M. gronoviæfolia*, Fisch. & Mey., is the same. By some authors, part of the species are separated as Nuttallia; also as Hesperaster.

A. *Plant herbaceous.*

B. *Color of fls. white, creamy white or yellowish white.*

decapétala, Urban & Gilg (*Bartònia decapétala,* Pursh. *M. ornàta,* Torr. & Gray. *Nuttállia decapétala,* Greene). Biennial or perennial, 2 ft. and more: lvs. 2–6 in. long, oval, lanceolate or oblong, sinuate-pinnatifid: fls. 5 in. across, opening toward night, fragrant, usually bracted; petals 10; stamens 200–300: caps. oblong, with numerous seeds. Dakota and Mont. to Texas. B.M. 1487. R.H. 1878:430.

nùda, Torr. & Gray (*Nuttállia nùda,* Greene). Biennial or perennial, st. somewhat slender, 1–5 ft. high: lvs. 1–3 in. long, lanceolate or oblong-lanceolate, acute, strongly dentate or pinnatifid: fls. opening toward night, creamy white, 1½–2½ in. across, usually bractless; petals 10. Mont., Kans., and Texas. B.M. 5483 (as *Bartonia nuda*).

BB. *Color of fls. yellow.*

Líndleyi, Torr. & Gray (*M. Bartònia,* Steud. *Bartònia aùrea,* Lindl.). Fig. 2361. Annual: st. 1–4 ft. high, simple or branched and straggling: lvs. 2–3 in. long, narrow-lanceolate to ovate, coarsely toothed or pinnatifid: fls. about 2½ in. across, bright yellow, very fragrant in the evening, bracted, opening in evening and remaining the following morning; petals 5, broadly obovate, nearly as broad as long, rounded at the apex except an abrupt short point. Calif. B.M. 3649. B.R. 1831. Gn.W. 21:504.

lævicaùlis, Torr. & Gray. BLAZING STAR. Biennial: st. stout, 2–3½ ft. high: lvs. 2–8 in. long, narrow-oblong to lanceolate, sinuate-toothed: fls. yellow, 2½–3 in. across, bractless; petals lanceolate or oblanceolate, acuminate. Wyo. to Calif.

AA. *Plant shrubby.*

Conzáttii, Greenm. Woody, 20 ft. and more: st. whitish: lower lvs. nearly opposite and upper alternate, simple, oblong-lanceolate, acuminate, finely dentate, the base entire and narrowed into a short petiole, scabrous above and tomentose beneath: fls. 2 in. across, brilliant yellow and showy, cymose-paniculate; calyx deeply 5-lobed; petals 5, ovate-oblong, short-acuminate. S. Mex. Listed in S. Calif.

L. H. B.†

MENYÁNTHES (Greek, probably meaning *month flower;* perhaps because it flowers for about a month). *Gentianàceæ.* BUCKBEAN. Perennial bog-plants.

As understood by the older botanists, the genus has two species, one of which is widespread in the U. S., and the other in the Pacific N.W. to Japan, but later botanists separate the latter plant as Nephrophyllidium (*N. crista-galli,* Gilg). Menyanthes has creeping rootstocks and small, 5-lobed white or purplish fls. in late spring. It is allied to Nymphoides, but the fls. of the latter are not bearded or crested on the face as they are in Menyanthes. Lvs. all alternate, stalked: corolla somewhat funnel- or bell-shaped; stamens inserted on the tube of the corolla; hypogynous glands 5; style long.

trifoliàta, Linn. BUCKBEAN. About 9–18 in. high: lfts. 3, oval or oblong-obovate, to 3 in. long: raceme 12–20-fld.: caps. small, ovoid. Bogs, temperate regions in N. Amer., Eu., and Asia. G.M. 43:335. G. 35:559. V. 2:198; 3:208.—The lvs. are said to be used in Germany as a substitute for hops in beer-making. A very interesting bog-plant, growing often in shallow water.

L. H. B.

MENZIÈSIA (after Archibald Menzies, surgeon and naturalist). *Ericàceæ.* Low deciduous shrubs, allied to Rhododendron, with small 4-merous fls. appearing with the lvs. in terminal clusters: corolla urceolate or bell-shaped, 4-lobed; stamens 8: fr. a 5-valved caps. with many linear caudate seeds. Seven species in E. Asia and N. Amer. Interesting shrubs for alpine rockeries, but not particularly ornamental. **M. pilòsa,** Juss. (*M. globulàris,* Salisb.), is sometimes offered by dealers in native plants. Shrub, 2–6 ft.: lvs. oval to oblong-obovate, glandular-mucronate, entire, strigose, ciliate, 1–2 in. long: fls. few, drooping, on slender glandular pedicels; corolla yellowish, often tinged reddish, ¼in. long; anthers included. May, June. Pa. to Ga. in the mountains. B.M. 1571. For cult., see *Andromeda* and *Rhododendron.*

M. cærùlea, Swartz=Phyllodoce cærulea.—*M. empetrifórmis,* Smith=Phyllodoce empetriformis.—*M. pentándra,* Maxim. Shrub, to 4 ft.: lvs. elliptic: fls. subglobose, greenish white; anthers exserted. Japan.—*M. polifòlia,* Juss.=Dabœcia polifolia.

ALFRED REHDER.

MERÀTIA (after François Victor Mérat, French physician and botanist, 1780–1851). Syn., *Chimonánthus. Calycanthàceæ.* Ornamental shrubs, grown chiefly for their early sweet-scented flowers; grown out-of-doors.

Deciduous or evergreen, with scaly winter-buds: lvs. opposite, without stipules, short-petioled, entire: fls. long before the lvs., on scaly branchlets axillary on branches of the previous year, with numerous imbricate sepals and without petals; stamens 5 or 6, short, with innate anthers; pistils many, inclosed in a hollow receptacle which develops into a caps.-like fr. with numerous achenes.—Two species in China. Often united with Calycanthus, which is easily distinguished by its naked winter-buds and the numerous stamens of the fls. which appear at the end of leafy shoots.

The species in cultivation is a deciduous shrub, in milder climates nearly evergreen, with generally oblong lustrous leaves and with fragrant yellow flowers with purple center appearing before the leaves in early spring. It is hardy about as far north as Philadelphia and likes a warm and sheltered position. See *Calycanthus* for cultivation and propagation.

præcox, Rehd. & Wilson (*Calycánthus præcox,* Linn. *Chimonánthus fràgrans,* Lindl.). Lvs. elliptic-ovate or oblong-lanceolate, acuminate, bright green, lustrous above, glabrous beneath, 3–5 in. long: fls. very fragrant, 1–1½ in. broad, outer sepals yellow, inner ones striped purplish brown. Feb., March. China, Japan. B.M. 466. L.B.C. 7:617. L.D. 3:173. G.C. III. 11:213. Gn.M. 5:141. Var. **grandiflòra,** Rehd. & Wilson (*Chimonánthus fràgrans* var. *grandiflòra,* Lindl.). Fls. much larger and brighter-colored. B.R. 451.—The evergreen *M. nìtens,* Rehd. & Wilson (*Chimonánthus nìtens,* Oliver), with long-acuminate lvs. and smaller and paler fls. (H.I. 16:1600) is not yet introduced.

ALFRED REHDER.

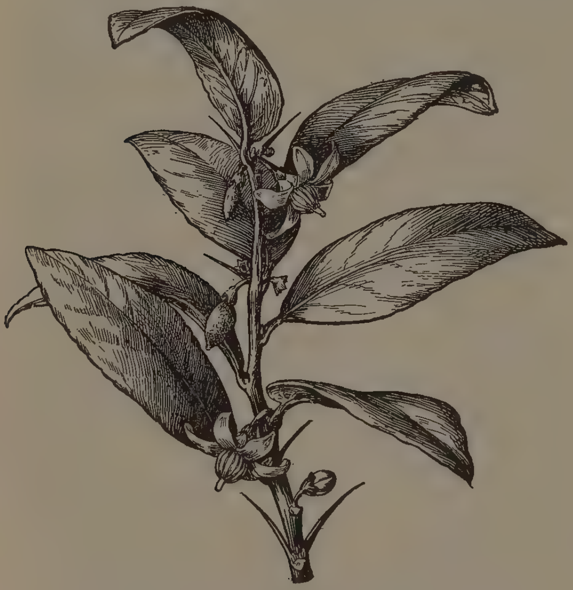
2361. Mentzelia Lindleyi. (×⅓)

MERCURIÀLIS (from Mercury, who is supposed to have discovered some virtue in the plant). *Euphorbiàceæ.* Mercury. Herbaceous plants of temperate regions, of little importance horticulturally. Lvs. opposite, simple: fls. apetalous, very small, in axillary clusters; calyx valvate; stamens 8–20, anther-cells spherical, attached by the apex and hanging; styles undivided; ovary 2–3-celled, 1 ovule in each cell. About 7 species, mostly in the Medit. region. Related to Mallotus and Acalypha. *M. ánnua,* Linn., is a weed in Eu. *M. perénnis,* Linn., is a European poisonous plant, the foliage yielding an unstable blue dye.

J. B. S. Norton.

MERENDÈRA (from *quita meriendas,* Spanish name of *Colchicum autumnale;* some of these plants formerly considered to belong to Colchicum). *Liliàceæ.* Small spring-blooming plants, classed as "bulbs;" little grown.

About 12 species of bulbous plants, mostly natives of the Medit. region and Asia, one in Abyssinia. They belong to the same tribe with Colchicum and Bulbocodium, but Colchicum has a real corolla-tube, while the other two genera have 6 very long-clawed segms. which are merely connivent, forming a loose tube at first and afterward separating. In Merendera there are 3 styles which are distinct from the base, while in Bulbocodium the style is 3-cut only at the apex. Merenderas are low stemless plants with tunicated corms: lvs. linear, appearing with the fls.: fls. 1–3, appearing in spring or fall, mostly lilac-colored. The genus is divided by Baker into two groups, based on the anthers. The 2 species described below belong to the group with small, oblong, versatile anthers, which are fastened at the middle rather than the base. They are hardy spring-blooming plants with about 3 lvs., and fls. 1–1½ in. across. These plants are procurable from Dutch bulb-growers. They are pretty, small-fld., hardy, fragile plants which persist well under good garden cultivation. The garden names are confused. *M. ruthenica* is probably *Bulbocodium ruthenicum,* which is a form of *B. vernum.*



2362. Flowering branch of Merope angulata. (Natural size)

A. *Blade of petals oblanceolate, obtuse.*

caucásica, Bieb. Lvs. 3–4, with the fls.: the 3 outer corolla-segms. appendaged on each side at the junction of blade and claw: new corms sessile. Caucasus, Persia. B.M. 3690.

AA. *Blade of petals lanceolate, acute.*

sobolífera, Fisch. & Mey. Lvs. 3, appearing with the fls.: segms. not appendaged: a very small new corm produced at the apex of a shoot. Asia Minor, Persia.—The plant cult. under this name is *Colchicum procurrens,* Baker, which differs from the Merendera in having a long perianth-tube, autumnal fls., and lvs. appearing in spring. The true *M. sobolifera* may not be in cult.

Wilhelm Miller.
L. H. B.†

MÉROPE (named for Merope, one of the Pleiades). *Rutàceæ.* Kigerukkan. A curious and as yet little-known salt-resistant plant related to Citrus, of interest for trial as a stock.

Small spiny tree: lvs. simple, thick and leathery; spines in pairs in the axils of the lvs.: fls. white, 5-merous with 10 free stamens: frs. triangular, having large flattened seeds imbedded in the sticky mucilaginous pulp.—Only one species is known.

angulàta, Swingle (*Cítrus angulàta,* Willd. *Scleróstylis spinòsa,* Blume. *Paramígnya angulàta,* Kurz.). Fig. 2362. A small spiny tree bearing curious angular frs. and growing in the tidal swamps in S. Java: lvs. coriaceous, thick, 3–5 x 1–1½ in., borne on simple petioles: fls. white, 5-parted with 10 free stamens, pistil projecting beyond the stamens: frs. triangular, 1–2 in. long, in cross section approximately an equilateral triangle ¾–1 in. on a side. Illus. Kurz., Journ. As. Soc. Bengal, 42 pl. 18 (1874). Valeton, Icon. Bogor, 4: pl. 348 (1912). Swingle, Journ. Wash. Acad. Sci. 5:420, figs. 1, 2 (1915).—This peculiar thick-lvd. plant thrives in saline soils and is being tested as a stock for other citrous frs. by the U. S. Dept. Agric.

Walter T. Swingle.

MERTÉNSIA (after Franz Carl Mertens, a German botanist). *Boraginàceæ.* Attractive herbs for colonizing and for borders.

Perennials, glabrous or pubescent: lvs. alternate, often having pellucid dots: racemes terminal or the cymes loose, few-fld., 1-sided, sometimes panicled; fls. blue or purplish, rarely white, with funnelform or campanulate corolla that is either crested or unappendaged in the throat, the lobes 5 and similar and not much spreading or the margin nearly entire; calyx 5-cut or 5-parted; stamens attached at the middle of the tube or higher; ovary 4-lobed, the style filiform: frs. 4 erect more or less wrinkled nutlets.—Species probably 40, in the cooler parts of the northern hemisphere, a good part in N. Amer. In recent years, the American species have been much redescribed. They are often very smooth plants, of attractive habit and bright colors. The most popular species is *M. virginica,* Virginia cowslip, bluebells, and Virginia lungwort. This grows 1–2 ft. high and bears more or less drooping clusters of blue-belled fls. in March to May. The fls. are about 1 in. long, and 20 or more in a terminal group. They have a purple tube and blue bell of distinct shape, the lobes of the corolla being little pronounced.

The common mertensia (*M. virginica*) is one of the plants that should remain undisturbed for years, and hence is suited to the rockery and to margins and ravines. It is unusually good for colonizing in woods. Its leaves die down soon after flowering-time. The plant should have a sheltered position and rich loamy soil. *M. sibirica* (of gardens) is considered by some even more desirable. The flowers are later, light blue, and not so distinctive in form. The foliage of *M. sibirica* lasts through the summer. Mertensias may be propagated by seed if sown as soon as ripe, but with uncertainty by division. Although of secondary importance, mertensias add variety to the border and are nearly always attractive to plant-lovers.

While *Mertensia virginica* grows well in full sun, it does almost as well in shady situations. It makes its growth early in the spring before the shade under the trees becomes very dense, and the foliage, which disappears after blooming, seems to ripen as readily in the shade as in the open. As large masses of this plant are effective, and as the blank left by the disappearing foliage precludes its being grown in the open border, it is fortunate that it will adapt itself to shady places where its yellowing foliage may be somewhat hidden and its absence during the summer be unnoticed. (W. C. Egan.)

INDEX.

alpina, 7.
chitralensis, 11.
ciliata, 5.
echioides, 9, 12.
elongata, 9.
lanceolata, 10.
maritima, 1.
oblongifolia, 3.
paniculata, 6.
papillosa, 8.
primuloides, 11.
pulmonarioides, 2.
rubra, 2.
sibirica, 4.
virginica, 2.

A. *Plant fleshy, glaucous and very smooth.*

1. **marítima,** S. F. Gray (*Pneumària marítima,* Hill. *Pulmonària marítima,* Linn.). Lungwort. On seacoasts from Mass. northward and in Eu. and Asia, likely to be planted in seaside places but apparently not in the trade: a spreading or ascending plant with branches 1 ft. or so long: lvs. fleshy, ovate to spatulate and oblong, entire, upper surface becoming blistered: fls. ⅓in. or less long, blue or whitish.

AA. *Plant not prominently fleshy, smooth or essentially so. (Nos. 9 and 10 may be sought here).*

B. *Fls. trumpet-shaped, the open part not prominently 5-lobed; filaments much longer than the anthers.*

2. **virgínica,** DC. (*M. pulmonarioìdes,* Roth). Virginian Cowslip. Bluebells. Fig. 2363. Vol. III, pl. LIII. Very smooth and glabrous, 1–2 ft.: lvs. obovate or oblong, or the lowest large, rounded and long-stalked; veins conspicuous: fls. at length more nodding than shown in Fig. 2363. Spring. N. Y. and westward to S. C. and Tenn., usually inhabiting low or moist grounds. B.M. 160 (as Pulmonaria). Gn. 23, p. 463, and 32, p. 173. J.H. III. 43:210. G. 6:115. Gn.M. 15:306. V. 3:181; 7:244; 11:180; 12:140. Mn. 4:33. Var. **rùbra,** Hort., has pink-colored fls.

BB. *Fls. with the upper part more bell-shaped and prominent spreading lobes; filaments shorter than the anthers or only a little longer.*

3. **oblongifòlia,** Don. About 12 in. high, smooth or very nearly so: lvs. mostly oblong or spatulate-lanceolate, somewhat succulent, veins inconspicuous: fls. blue in a rather close cluster, the corolla-tube 2–3 times length of the limb and also of the calyx; calyx-lobes acute. Mont. to Wash.—Not easy to cult.

4. **sibírica,** Don. Glabrous, 1–5 ft. high: lvs. roundish or broadly elliptic, somewhat fleshy, the upper ones very acute or acuminate and ovate: fls. purplish blue, in long racemes; the fls. sometimes vary to white. E. Siberia. Gn. 18:514.—Offered by some American dealers.

5. **ciliàta,** Don. The N. American plants heretofore referred to *M. sibirica* are now separated as *M. ciliata,* being specially marked by a short calyx with oval or oblong obtuse cilate lobes: glabrous, pale and glaucescent, very leafy, 1–3 ft.: lvs. oblong or lance-ovate, ciliate on the margins, mostly acute or acuminate, the basal ones ovate or subcordate: fls. bright blue, the tube 3–5 times as long as the calyx-lobes. Rocky Mts W. and N.; also in the trade. G. 27:661.—A handsome species, with bell-shaped blossoms and pinkish buds.

6. **paniculàta,** Don. Greener than *M. sibirica,* roughish and more or less pubescent: st.-lvs. ovate to oblong-lanceolate: fls. blue, in loosely panicled racemes; calyx-lobes acute, lanceolate or linear. Lake Superior and north, E. Asia. B.M. 2680 and B.R. 146 (as *Pulmonaria paniculata*).

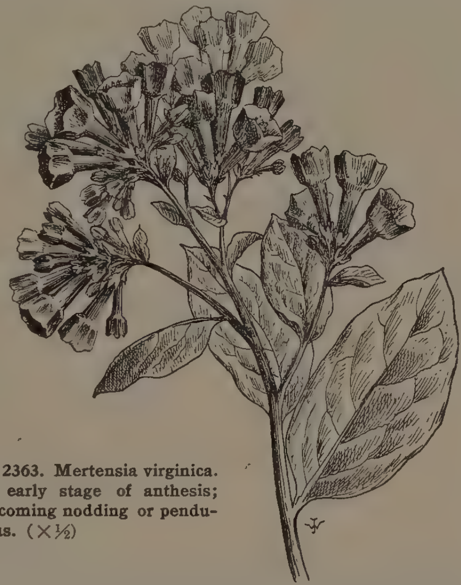
7. **alpìna,** Don. Mostly smooth and somewhat glaucous but sometimes pubescent, only a few inches high: lvs. oblong, spatulate or lanceolate, somewhat obtuse, the cauline sessile: fls. blue, crowded, corolla ⅓–¼ in. long, the tube rarely exceeding the corolla-limb and equally or slightly exceeding the lanceolate calyx-lobes; anthers nearly sessile. Subalpine places in the Rocky Mts.

AAA. *Plant not prominently fleshy, more or less hairy (at least the lvs.).*

B. *Corolla-tube little if any longer than calyx.*

8. **papillòsa,** Greene. Sparingly leafy, 12 in. or less high: lvs. oblong and revolute, densely papillose (with many minute projections) and hairy above, smooth beneath, scabrous on margins: fls. blue, panicled, the corolla small and almost tubular, with a narrow limb and shallow lobes. Mountains of Colo.—Offered in the W.

9. **elongàta,** Benth. (*M. echioìdes* var. *elongàta,* Hort.?). Sts. 8 in., hairy: lvs. somewhat hairy, oblong to spatulate, the cauline sessile: fls. blue, in many-fld. elongating racemes, the corolla-tube little exceeding the calyx, the throat bearing very small scales and the lobes spreading. Kashmir. G.C. III. 47:390 (as *M. echioides* var. *lanceolata*).



2363. Mertensia virginica. In early stage of anthesis; becoming nodding or pendulous. (×½)

BB. *Corolla-tube conspicuously longer than calyx.*

10. **lanceolàta,** DC. Dwarf, 8 in. or less high: lvs. closely or minutely pubescent on upper surface but otherwise glabrous, glaucescent, spatulate to lance-linear, somewhat fleshy: fls. blue (buds pink) in early spring, loosely paniculate; corolla-tube hairy within at the base, usually nearly twice as long as calyx. Plains and hills, Wyo., Colo.—Offered W., as a choice rock-plant, thriving in any light soil.

11. **primuloìdes,** Clarke. Dwarf, the st. about 3–6 in. long and very leafy below, hairy: lvs. small, elliptic or lanceolate, the lower ones very short-petioled: fls. about ½in. across, indigo-blue passing into white and yellow, on very short pedicels in few-fld. dense short racemes, the corolla-tube twice longer than calyx, the throat bearing distinct scales. High Himalayas. Gn. 69, p. 319. F.S.R. 1:246. Var. **chitralénsis,** Hort., has larger and more deeply colored fls. N. W. India.

12. **echioìdes,** Benth. St. 12 in. more or less: plant soft-hairy: lvs. oblong to spatulate, the lower ones long-

petioled, somewhat obtuse: fls. deep blue in dense many-fld. racemes, the corolla-tube one-third longer than calyx, with no scales in the throat, the lobes of corolla erect. Himalaya. WILHELM MILLER.
L. H. B.†

MÉRYTA (from the verb *to roll*, because of the character of the male fls.). *Araliàceæ.* Glabrous small trees of the S. Pacific Isls., perhaps 15 species, with large alternate simple coriaceous lvs.: fls. diœcious, small, in terminal panicles, the sterile with 4 or 5 stamens, the fertile with 4- to many-celled ovary; petals 4 or 5; calyx-limb none or minutely toothed. *M. Sínclairii,* Seem. (*Botryodéndrum Sínclairii,* Hook.), the PUKA, is one of the rarest plants in New Zeal., but is considerably planted in the northern part where it makes a striking round-headed evergreen tree to 25 ft. high, with large oblong or obovate shining lvs. crowded near the ends of the branches and terminal stout panicles of greenish white fls.: fr. small, ½in. or less long, succulent, black. It is intro. in England, and is well worth trying in Calif. G.C. III. 34:422; 45:2. *M. Dénhamii,* Seem., has been cult. for some time at Kew and is used as a stock on which to graft *Aralia* (*Dizygotheca ?*) *Veitchii.* It is a tree growing 30 ft. or more, with variable narrow lvs. a ft. or two long. S. Sea Isls. B.M. 7927. L. H. B.

MESEMBRYÁNTHEMUM (Greek, *midday flower;* the flowers usually open in sunshine and close in shadow). Sometimes spelled *Mesembrianthemum. Aizoàceæ.* FIG-MARIGOLD. Mostly low-growing succulents, grown as pot subjects under glass or in window-gardens and sometimes planted out in summer; some kinds are good bank-covers in mild climates.

Annual or perennial prostrate or erect herbs, and sometimes subshrubs, with thick fleshy usually opposite lvs. which are 3-angled, terete or flat, and with entire or more or less spiny margins: fls. white, red or yellow, mostly terminating the branches, usually opening in full sun but a few expanding in the evening; calyx mostly 5-parted, the lobes usually lf.-like and unequal; petals very many, linear, in 1 to many rows, united at the base; stamens very numerous, also in many rows and united at base; ovary mostly 5-celled (but variable): caps. 5- to many-celled, stellately dehiscing at the summit, becoming baccate, hygroscopic; seeds very numerous.—Mesembryanthemum includes some 300 and more species, nearly all of which are S. African, according to Sonder "abounding throughout the arid plains and sands of the whole country to the south of the Orange River and west of the Great Fish River." Four species are described by Bentham in Flora Australiensis. Two (*M. crystallinum* and *M. equilaterale*) are native in Calif. Others occur in New Zeal., Canaries, Arabia and the Medit. region. They are allied botanically to the cactaceous series, although lacking the spines of those plants and bearing true lvs. Horticulturally, they are fanciers' plants, and are classed with "succulents." Very few are in the general trade, although a number are advertised in Calif. and others are in botanic gardens. As with most succulents, the species are not well understood botanically, owing largely to the difficulty in making herbarium specimens. Many of them are of odd and grotesque form. One species, *M. crystallinum,* is a common house-plant, being known as ice-plant, but it is one of the least showy in fl. It is grown for the thick glistening foliage. It prop. readily by seed or division. The best available account of the mesembryanthemums is Sonder's elaboration of the S. African species (293 numbers) in Flora Capensis, Vol. II (1861–2), from which the following treatment has been largely taken. Sonder writes that "the caps. are tightly closed in dry weather and open naturally after rain. If thrown into water until it becomes thoroughly soaked and then removed, an old caps. will open out its capillary valves, radiating from a center like a star; and will close them again when dry. This experiment may be repeated several times without destroying their remarkable hygrometric property."

In sunny and semi-arid regions the fig-marigolds are very appropriate and attractive, covering the soil with plump foliage and giving a display of brilliant colors. They are also used more or less in bedding-out on south borders and exposures in cooler and moister climates.

2364. Mesembryanthemum felinum. (×⅓)

M. edule has extensively run wild in many parts of the world and is useful in covering banks and holding loose sands. It withstands some frost. Any number of species may be found in the collections of fanciers, and many not described below are mentioned in periodical literature, but they need not be entered here as they are really not horticulturally known. See *Succulents.*

The cultivation of the fig-marigolds should consider their natural conditions. They are found in their native habitats growing most luxuriantly on dry barren rocky places and on dry sandy plains. They are succulent plants with thick fleshy leaves, and are therefore able to stand the severe drought they have to put up with in those arid places. Knowing that these plants delight in dry arid situations gives the key to their cultivation. When grown in pots, care should be taken that the pots are well drained. A light sandy loam, mixed with brick rubbish broken small, makes a good compost for them. In summer they may be placed out-of-doors in a slightly elevated and sunny position, where they will produce an abundance of their showy blossoms. On the approach of cold weather in autumn they may be placed in a cool greenhouse with a dry atmosphere and plenty of air. Very little water is needed during the dull months of winter. Some of the species make good window plants. *M. cordifolium* var. *variegatum* is largely grown for edgings for beds. *M. pomeridianum* and *M. tricolorum* are good showy annuals. Propagation is effected either by cuttings or by seeds. Cuttings should be dried in the sun for two or three days before they are inserted in sand. (Robert Cameron.)

In the following account, the species are all South African unless otherwise specified.

A. EPAPULOSA: *Plant not bearing glittering papillæ or projections (species 1–35).*

B. *Plant stemless or nearly so.*

C. *Lvs. 2, minute, united into a globe.*

1. **mínimum,** Haw. Stemless, when cult. often somewhat caulescent, obconical, with confluent rather branched dots: fls. whitish; petals connate at base; ovary exserted. G. 1:437.

CC. *Lvs. distinct.*

D. *Fls. yellow (Nos. 2–12).*

E. *Lvs. 4–6, semi-terete at the base, thickening and triquetrous at the apex.*

2. **tigrìnum,** Haw. TIGER'S JAW. Stemless or essentially so: lvs. cordate-ovate, 2 in. or less long, glacuous green and marbled with white, the upturning edges with long, soft, ciliated teeth, the keel entire: fls. nearly sessile, large, yellow. B.R. 260. Gng. 16:227. G.L. 19:138; 27:226. A.F. 30:376.

3. **felìnum,** Haw. Fig. 2364. Lvs. triquetrous, rhomboid-lanceolate, 2 in. or less long, but narrower than in the last, somewhat glaucous, faintly dotted with white, the edges with 8 ciliate teeth; keel entire: fls. nearly sessile, yellow.

EE. *Lvs. 4–6, triquetrous, thickened from the base to the middle, but tapering to the apex.*

4. **albinàtum,** Haw. Stemless: lvs. curved-triquetrous upward, with a recurved mucro or spine at the apex, bearing elevated whitish dots: fls. sessile, yellow.

EEE. *Lvs. half-cylindrical, of various sizes or forms on the same plant, in alternate pairs.*

5. **angústum,** Haw. Nearly or quite stemless, small: lvs. 2-ranked, linear, tongue-shaped, long, keeled at the apex, somewhat unequal, one of them straight-acute and the other hooked: fls. nearly sessile, yellow.

6. **bigibberàtum,** Haw. Rather caulescent: lvs. small, scarcely tongue-shaped, very smooth, usually with 2 gibbosities, subequal, one attenuated and acute, the other keeled-dilated, obtuse at the apex: petals denticulate.

7. **Sálmii,** Haw. Nearly stemless: lvs. decussate, attenuate, one acute, the other oblique and blunt, 6–8, with a white spot at the inside of base: fls. sessile.

EEEE. *Lvs. tongue-shaped, with one margin thicker than the other, of two or more forms, 2-ranked.*

F. *Peduncle less than 1 in. long.*

8. **linguæfórme,** Haw. Lvs. unequally tongue-shaped, deflexed and somewhat falcate, becoming depressed when old, flattish above, obliquely attenuate: fls. yellow. Index Kewensis makes the *M. linguæforme* of Haworth synonymous with *M. obliquum,* Willd., and uses Linnæus' *M. linguiforme* as a tenable name.

9. **uncàtum,** Salm-Dyck. Nearly stemless: lvs. narrow tongue-shaped, 2½ in. long, thick, incurvate-uncinate at apex: fls. yellow; petals revolute.

FF. *Peduncle 1 in. or more long.*

10. **cultràtum,** Salm-Dyck. Lvs. 2-ranked, thick, tongue-shaped and curved like a pruning-knife, blunt at the apex: fls. yellow, on a somewhat 3-angled peduncle.

11. **depréssum,** Haw. Prostrate: lvs. narrow, tongue-shaped, recurved-depressed, acute: fls. yellow, with petals somewhat recurved.

12. **pustulàtum,** Haw. Lvs. 2-ranked, narrow, tongue-shaped, long and ascending, blunt, bearing pustules near the base: fls. yellow.

DD. *Fls. white or reddish.*

13. **pubéscens,** Haw. Almost stemless: lvs. silky-pubescent, semi-cylindrical, oblique at apex: fls. bright rose-red. Gt. 59:1579 and p. 13.

14. **calamifórme,** Linn. St. 1–2 in. long, woody: lvs. glaucescent, cylindric, with a much-thickened base: fls. in short stout peduncles, solitary, white with pink tips, 2½ in. across. B.M. 7775.

BB. *Plant with an evident erect or prostrate st.*

C. *Foliage-lvs. distinct or essentially so (not truly perfoliate nor connate).*

D. *St. or caudex prostrate.*

E. *Branches angular: lvs. acinaciform with smooth angles.*

F. *Peduncle with 2 bracts.*

15. **acinacifórme,** Linn. St. articulate, 2–3 ft. long, the young growth compressed: lvs. opposite, 2–3 in. long, scimitar-shaped (curved and thicker on one edge), the keel dilated: fls. purple, about 4 in. across, "the largest in the genus," the stigmas 14: fr. size of a gooseberry, and eaten by Hottentots. Gn. 62, p. 362. Gt. 59, p. 15.—Handsome.

16. **rubrocínctum,** Haw., is probably a form of the last, differing in having a red line on the keels of the lvs. B.R. 1732.

17. **æquilateràle,** Haw. Differs from *M. acinaciforme* chiefly in thinner lvs. and smaller fls.: sts. several feet long, often forming large mats: lvs. 3-sided, thicker than broad, to 2 in. long: fls. fragrant, to 2 in. across, bright rose-purple, showy and fragrant. Native to Austral., Tasmania, Chile and Calif. Grows on dunes and banks near the sea.

FF. *Peduncle without bracts.*

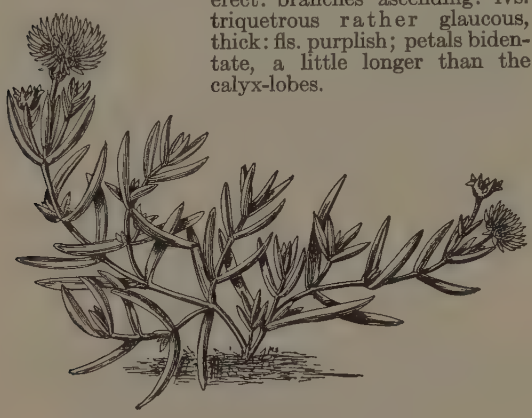
18. **edùle,** Linn. Fig. 2365. St. angular: lvs. opposite, 3–4 in. long, triquetrous, curved, the keel serrate:

2365. Mesembryanthemum edule.—Hottentot fig.

fls. large, yellow or purple, the stamens 8: fr. edible, being one of the Hottentot figs.—Grows well on the sea-cliffs in S. England, making long hanging masses (Gn. 55, p. 235, with picture); also used in Calif. and elsewhere to hold sand and to provide ground-cover. Gn. 71, p. 600.

EE. *Branches angular or terete; lvs. subacinaciform, with serrulated angles.*

19. **serrulàtum,** Haw. St. shrubby, when young erect: branches ascending: lvs. triquetrous rather glaucous, thick: fls. purplish; petals bidentate, a little longer than the calyx-lobes.



2366. Mesembryanthemum aureum. (×⅕)

DD. *St. or at least the branches, erect or prominently ascending.*

E. *Fls. yellow, orange or copper-color.*

20. **aurantìacum,** Haw. St. becoming 1 ft. or more high, much branched, sometimes decumbent at base, the branches somewhat compressed: lvs. 1 in. or less long, smooth and glaucous, bluntly triquetrous: fls. orange, with petals ¾in. long and in about 3 series.

21. **aùreum,** Linn. Fig. 2366. Larger: lvs. 1½–2 in. long, cylindrically triquetrous, smooth and glaucous, mucronate: fls. golden, 2 in. across, the petals in many series. B.M. 262.—In this and the last, the lower lvs. are often nearly connate at the base.

EE. *Fls. rose-color or purplish.*

F. *Lvs. triquetrous, carinal angles drawn out, often lacerate: branches 2-edged.*

22. **mutábile,** Haw. With straw-color or reddish tortuous, erect branches: lvs. about ½in. long, compressed-triquetrous, incurved, the keel entire, apex acute: fls. mostly solitary on an upwardly thickened peduncle, rose-color, the inner short petals pale yellow.

23. **inclaùdens,** Haw. Distinguished from the last by scimitar-shaped lvs. and broader petals: lvs. crowded, green, compressed-triquetrous and scimitar-shaped (thicker on one edge).

24. **lácerum,** Haw. St. erect, branches spreading: lvs. glaucous, 1½–2 in. long: fls. often solitary, large; petals numerous, inner ones short, exterior ones longer than calyx, rose-colored.

25. **heteropétalum,** Haw. St. and branches erect-spreading: lvs. glaucous, subfalcate: fls. small, solitary, rarely geminate; petals pale red or whitish, interior ones very short.

FF. *Lvs. subtriquetrous, elongated, acute, very smooth: branches erect, rigid.*

26. **blándum,** Haw. Two ft., with numerous branches: lvs. distant, 2 in. or less long, compressed-triquetrous, but with equal sides, narrow, minutely dotted, acutish: fls. 2 in. across, pale rose, the petals toothed. B.R. 582. L.B.C. 6:599.

FFF. *Lvs. subconnate, triquetrous, with equal sides, gradually attenuated: branches suberect.*

27. **spectábile,** Haw. St. prostrate, but branches ascending: lvs. 2–3 in. long, crowded, glaucous, incurved and spreading, triquetrous, attenuate and mucronate: fls. purplish; petals 1 in. long, the inner somewhat shorter. B.M. 396. G.W. 14, p. 649.

FFFF. *Lvs. falcate-recurved, with obtuse angles.*

28. **falcifórme,** Haw. One to 2 ft., branches spreading: lvs. much crowded, triquetrous, angles acute: fls. in 3's or solitary, 1½ in. diam., showy; petals in many series, lanceolate; filaments white. J.H. III. 50:493.

29. **ròseum,** Willd. To 2 ft. high, branches spreading, leafy: lvs. attenuate on both ends, incurved: fls. in 3's or solitary, showy; petals pale rose-colored, in two series. Gn. 62, p. 363.—One of the common species in Calif., extensively used in parkings and in terraces where it is difficult to secure a grass sod, and for covering rocks behind retaining-walls. If given water, the foliage has a rather dark green color, but if grown without watering it is grayish green and the fls. are somewhat smaller although not less brilliant.

FFFFF. *Lvs. compressed-triquetrous, with dilated keel near recurved apex, not toothed.*

30. **cauléscens,** Mill. Shrub to 1½ ft.: lvs. incurvate-erect, glaucous, acutish, with the sides obtuse, toothed and the keel entire: fls. in 3's, or often solitary; petals obtuse, emarginate.

31. **muricàtum,** Haw. St. suberect: plant bluish: lvs. less than ½in. long, somewhat incurved, deltoid and toothed, very glaucous: fls. small and fragrant, the petals acute.

CC. *Foliage-lvs. truly connate or perfoliate.*

D. *Lvs. triquetrous.*

32. **uncinàtum,** Linn. St. diffuse, much branched: lvs. sheathing at base, glaucous-green, punctate, short and equal-sided, triquetrous, often furnished with 1 or 2 spines underneath at the apex: fls. on short, thick peduncles, ½in. diam., rose-colored. Hardy in England.

33. **acutángulum,** Haw. St. shrubby, with rigid and erect branches: lvs. sheathing, ½in. long and about as long as the internodes, glaucous green, triquetrous, compressed near the apex, somewhat incurved: fls. white, small, in a panicle.

DD. *Lvs. elongated, subulate or somewhat cylindrical.*

34. **stipulàceum,** Linn. Dwarf, with erect, decussate branches: lvs. 1½–2 in. long, very slender, crowded, spreading and recurved, very glaucous: fls. in the axils, mostly solitary, purplish.

35. **Lèhmannii,** Eckl. & Zeyh. Branches compressed, ascending: lvs. spreading, subconnate, turgidly triquetrous, without dots, very smooth, glaucous: fls. terminal, solitary, on short peduncles, 1–1½ in. diam.; calyx 6-cleft; petals in many rows, interior ones shorter, pale yellow.

AA. PAPULOSA: *Plant usually bearing glittering papillæ, vesicles or projections on sts. and lvs.,—hence the popular name ice-plant (species 36–51).*

B. *Lvs. flat.*

C. *Stigmas 5.*

D. *Root annual or biennial (cult. as annuals).*

36. **crystállinum,** Linn. ICE-PLANT. Fig. 2367. A common plant in window-gardens and hanging-baskets and readily grown from seeds (which are offered by seedsmen), procumbent: lvs. flat, fleshy, ovate or long-spatulate, usually clasping, undulate, covered with glistening dots or elevations: fls. small, whitish or varying to light rose-color. S. Afr., Greece, Canary Isls., S. Calif. G. 2:147.—Grown for its glistening foliage. Fls. open in the sun.

37. **pinnatífidum,** Linn. f. Sts. diffuse: lvs. obovate, 1–2 in. long, lyrate pinnatifid: fls. axillary, solitary, pedunculate; petals as long as calyx, yellow. B.M. 67.

DD. *Root annual.*

38. **pyropèum,** Haw. (*M. trícolor* and *M. tricolòrum,* Hort.). Almost stemless, branched from the base: lvs. connate, radical or rising from the base of the st., linear-elongate, semi-cylindrical: fls. solitary, pedunculate, variable in color from light pink with red eye to self-colored white, pink and red. B.M. 2144. G.C. III. 43:42. G.M. 54:299.

DDD. *Root perennial and the st. becoming somewhat woody.*

39. **cordifòlium,** Linn. Sts. 1–2 ft., diffuse, minutely papillose: lvs. opposite, 1 in. or less long and nearly as wide, cordate-ovate, somewhat papillose: fls. solitary, peduncled, purple, the petals short and linear. A var. **variegàtum** is in cult., and is a good half-hardy trailing plant.

CC. *Stigmas 10–20.*

40. **pomeridiànum,** Linn. St. simple or forking, the branches ascending, hairy on branches, peduncles and calices: lvs. lance-spatulate or spatulate, narrowed into a petiole, ciliate: 2 of the calyx-lobes longer than the petals; petals linear-lanceolate. B.M. 540.

41. **glàbrum,** Ait. Glabrous: lvs. lance-spatulate, petiolate and dilated at base: fls. straw-colored, darker at the eye; lobes of the calyx linear and unequal.

BB. *Lvs. terete or nearly so.*

C. *Branches hispid or bristly.*

42. **subcompréssum,** Haw. Erect, 2 ft.: lvs. not crowded, ¾in. or less long, narrow, very blunt, greenish canescent, flattened-terete: fls. solitary, purplish; calyx-lobes unequal.

43. **floribúndum,** Haw. Tortuous in growth, the branches not over 6 in. long, more or less decumbent: lvs. less than 1 in. long, very narrow, terete, curved, obtuse, a little thicker toward the apex: fls. small, axillary, rose-color, the 5 styles exserted, the petals twice longer than the calyx.

CC. *Branches not hispid.*

D. *The lvs. barbate at the apex.*

44. **barbàtum,** Linn. A foot or more tall, diffuse and decumbent: lvs. not crowded, ½in. long, spreading, green and pellucid, semi-cylindrical, with 5 or 6 hairs at the end: fls. solitary, reddish, the petals entire and 2–3 times longer than the calyx.

2367. Common ice-plant—Mesembryanthemum crystallinum. (×¼)

45. **stellàtum,** Mill. Three or 4 in. high, fleshy and tufted: lvs. crowded, ⅓in. long, glaucous, semi-cylindrical, scabrous, with many hairs at the apex: peduncles hairy: fls. reddish violet, the calyx campanulate, ¼in. long.

46. **dénsum,** Haw. Much like the last: lvs. longer, flattish above and convex beneath, ciliate also at the base: calyx longer: fls. reddish violet. R.H. 1869, p. 356.

DD. *The lvs. punctate-scabrous.*

47. **élegans,** Jacq. (*M. defléxum,* Haw.). Shrubby, 6–12 in. or more tall, branchy, whitish or red: lvs. crowded, ½in. long and very narrow, very glaucous, scabrous: fls. numerous, mostly panicled, pale red (or whitish), the petals ½in. long.

48. **polyánthum,** Haw. Subshrub to 1 ft., much branched: lvs. much crowded, erect-spreading, very narrow, compressed-semiterete, bluish glaucous, prominently dotted: fls. very numerous, ternately panicled; petals rosy violet.

49. **violàceum,** DC. Distinguished from the preceding by the more robust, erect st., less diffuse branches, lvs. longer and a little incrassate: fls. numerous, very long-peduncled, ternately panicled; petals entire, twice longer than calyx, violet.

DDD. *The lvs. minutely papulose.*

50. **subincànum,** Haw. Root woody, branched, fibrous: st. erect, branched: lvs. connate, spreading, without dots or papulæ, recurved and mucronulate at the apex: fls. trichotomous, subcorymbose, fragrant, white.

51. **Ecklònis,** Salm-Dyck. Root woody, branched: st. and branches pubescent, at length glabrate: lvs. depressed triquetrous, minutely papillate and hairy: fls. in 2's or 3's, subtrichotomous, ½in. diam., white.

L. H. B.

MESOSPINÍDIUM (Greek compound; meaning obscure). *Orchidàceæ.* Plants with the habit of a slender odontoglossum, with sheathing leaves at the base of the pseudobulbs.

Flowers in racemes on panicles; sepals and petals sub-similar, expanded; labellum with 2 longitudinal ridges, adnate to the column, with rounded lateral lobes and a narrow middle lobe; column long or short; pollinia 2, seated on a rhomboid pedicel. These plants are evergreen coolhouse orchids, and thrive well in baskets of peat and moss, with plenty of water. The plants cult. as Mesospinidium are referred by some to the genus Cochlioda. Mesospinidium has about 5 species, of which the following is often cult.

sanguíneum, Reichb. f. Pseudobulbs oval, 2-lvd., mottled: lvs. ligulate, sharp-pointed, shorter than the many-fld. drooping panicle: fls. numerous, small, vivid rose; the lower sepals are partially united, oblong; petals cuneate-ovate. Peruvian Andes. B.M. 5627.

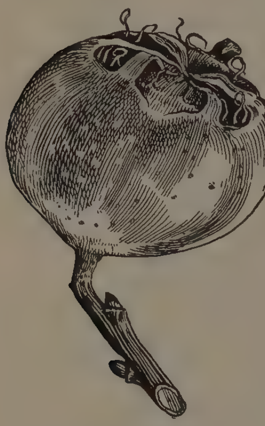
M. vulcánicum, Reichb. f., is described as Cochlioda vulcanica (Vol. II, p. 809), its proper name.

HEINRICH HASSELBRING.

MÉSPILUS (Greek substantive name of doubtful significance). *Rosàceæ.* MESPIL. MEDLAR. Woody plants, grown in Europe for the edible fruit and sometimes planted in this country.

From Pyrus, with which this genus is sometimes united, Mespilus differs in bearing the fls. singly on leafy growths of the season (the frs., like the quince, having no true detachable peduncles as do pears and apples), and in having the top of the ovaries not covered by the over-growing receptacle, and the pyrenes readily separable. There is but one species of true Mespilus, although some authors (e.g., Focke, in Engler & Prantl's "Die Natürlichen Pflanzenfamilien") include some of the Cratægus species in the genus. From Cratægus it differs in its fr. (as from Pyrus), in the large fls. borne singly, and the more leaf-like calyx divisions.

germánica, Linn. MEDLAR. Fig. 2368. The only recognized species: small tree, or sometimes only shrub-like, thorny in the wild but usually unarmed in cult.: lvs. simple and nearly sessile, lance-oblong or elongated-oblong, pubescent, serrate: fls. large and sessile on short leafy shoots, white or pinkish, pubescent outside; styles usually 5, glabrous and distinct; top of the hypanthium pubescent: fr. a pome with open top bearing a more or less hairy disk and from which the pyrenes or stones partially or slightly protrude. Var. **gigantêa,** Kirchn. (var. *macrocárpa,* Hort.), is a large-fruited form. Var. **abortìva,** Kirchn. (var. *apyrèna,* Koch), is a seedless form. Cent. and S. Eu. to the Caucasus, and also wild in England but probably not indigenous there. G. 4:363. It hybridizes with Cratægus (see *Cratægo-Mespilus,* Vol. II, p. 878).



2368. Medlar—Mespilus germanica. (Natural size)

The medlar is grown to a considerable extent in parts of Europe for its acid fruits, but in this country it is very little known. It is perfectly hardy in central New York, and its cultivation requires no special treatment or skill. It makes a twiggy tough-wooded bush or small tree, 10 to 15 feet high, bearing large white blossoms late in May or early in June, after the leaves are full size. The foliage is soft and luxuriant. The fruit (Fig. 2368) remains hard and austere until mellowed by frosts. With the freezing and the incipient decay, the fruit becomes brown and soft. It is usually picked after it is touched by frost and laid away on shelves or in drawers in a cool dry room; the ripening process which follows is known as bletting. When finally softened, it is agreeable for eating from the hand, particularly for those who enjoy fruit-acids. It also makes good preserves. Medlars are easily raised from seeds, although seeds (like those of Cratægus) may not germinate the first year. On these stocks the named varieties may be grafted or budded. Medlars may also be worked on pear, thorn (Cratægus) or quince. The Dutch or Hollandish and the Nottingham are the leading varieties. The fruit of the former is often 2½ inches in diameter. The latter is much smaller, but is better in quality. There is also a seedless variety, and two variegated forms.

M. arbutifòlia, Linn.=Aronia arbutifolia.—*M. grandiflòra,* Smith=Cratægus grandiflora (see Vol. II, p. 888).—*M. japónica,* Thunb.=Eriobotrya japonica.—*M. Pyracántha,* Linn.=Pyracantha coccinea.—*M. Smíthii,* DC.=Cratægus grandiflora.

L. H. B.

MESQUIT of Mexico is *Prosopis juliflora* (Leguminosæ). A picture of a mesquit forest is shown in G. F. 1:116.

METAPLÉXIS (Greek, referring to relationships of the corona parts and stamens). *Asclepiadàceæ.* Three twining shrubs of Japan, N. China and Siberia, little grown: lvs. opposite, cordate: fls. medium or small, in pedunculate clusters. *M. Staùntonii,* Roem. & Schult. (*M. chinénsis,* Decne. not Turcz.), has acuminate undulate lvs.: racemes extra-axillary, peduncled, the fls. pale rose or greenish white, small: likely to kill to the ground and to send up long herbaceous blooming shoots. China. G. 32:661.

METHÓNICA: *Gloriosa.*

METROSIDÈROS (Greek, *heart of iron;* this and other genera of the myrtle family are called ironwoods). *Myrtàceæ.* BOTTLE-BRUSH. Trees and shrubs, sometimes climbers, more or less planted for the showy red or white long-stamened flowers.

Leaves coriaceous, mostly opposite, sometimes distichous: fls. red, crimson, or white, mostly in terminal cymes or racemes; petals 5, spreading; stamens very numerous, 1 in. or more long, much longer than the petals; ovary 3-celled, with filiform style: fr. a coriaceous caps., inclosed in the persistent calyx-tube or protruding, the seeds numerous, linear.—The species described below are coolhouse shrubs, and are rarely grown outdoors in the S. The genus has about 20 species, half in New Zeal., and others in Pacific Isls. and Austral., 1 in S. Afr. Some of the species are brilliant when in bloom, although they have been only sparingly intro. to cult. *M. robusta* is the remarkable "rata" of New Zeal., of which Cheeseman writes: "A magnificent tree, sometimes reaching a gigantic size, specimens having been measured with trunks over 20 ft. diam. It usually (but not invariably) commences life as an ephiphyte in the upper branches of some tall forest-tree, sending to the ground aërial roots, which coalesce and form a trunk after the death of the supporting plant. Terestrial specimens are frequently seen, but these either have no trunk at all, keeping during life the habit of a much-branched bushy shrub, or produce a short, hard, and durable wood, which is much employed for wheelwrights' work, framework for machinery, wagons, etc., and for shipbuilding."

The plants belong to the class of Australasian shrubs whose chief beauty lies in their long red stamens. They are somewhat grown for a fancy Easter trade by florists, largely from imported stock. They are allied to Callistemon, and at least some of the *M. floribunda* of the trade is *C. lanceolatus.* In Metrosideros the flowers are borne in dense two- or three-forked cymes, while in Callistemon they are borne in spikes. In Fig. 745 (page 630) the plant is shown with apparently terminal inflorescence, but the branch is really terminated by the leaf-buds, which develop later. *M. semperflorens,* Lodd.=Callistemon lanceolatus.—*M. speciosa,* Sims=Callistemon speciosus.

The plant known to the trade as *Metrosideros robusta,* Fig. 2369, and which is probably *Callistemon lanceolatus,* has been grown for many years as a cool greenhouse plant, but it is only within recent time that Europeans have been sending American florists the compact little bushes that arrive with the azaleas. The city florist can perhaps dispose of one of these bottle-brushes for every ten plants of *Azalea indica.* Plants in 6-inch pots, well flowered, fixed with a red ribbon and placed in a modern basket, certainly look novel and attractive. The Belgians grow the young plants in peat, as they do most hard-wooded plants, but they do very well in good turfy loam with a fourth of leaf-mold. Cuttings of the young growth may be struck in early spring and planted out in good soil by the end of May, but it is cheaper to import stock. When the plants arrive, soak the ball of roots, pot firmly and place them in a house of about 45°. Freshly imported plants cannot be forced in much heat, like azaleas, or they will shed their flowers. Watch them carefully, give them more heat gradually and they will bloom for Easter. Plants unsold the first spring will be much more satisfactory the second year. By the end of April cut them

2369. Metrosideros floribunda of the trade, but Callistemon lanceolatus of the botanists.

back to within 1 or 2 inches of the old growth, put them in a good heat and keep them syringed. They will make a bushy growth, with a good number of shoots. Early in June plunge them in a sunny spot outdoors, with the rim of the pot well covered, and be careful that they do not suffer for water in hot weather. In July, or earlier, mulch the pots with an inch of half-decomposed cow-manure. Before frost, remove the plants to a temperature of 45° or warmer if bloom is desired before Easter. (William Scott.)

A. *Fls. red.*

robústa, A. Cunn. Large forest tree, to 100 ft., with an irregular trunk: lvs. opposite, elliptic-ovate to elliptic-lanceolate, 1–1½ in. long, glabrous, very coriaceous, obtuse, veiny, with an extra nerve near each margin and parallel: fls. dark scarlet, many in broad and dense terminal cymes; calyx top-shaped. New Zeal. B.M. 4471 (erroneously as *M. florida*). R.B. 24:269.—Probably not in the trade, the plant sometimes known by this name being *Callistemon lanceolatus*. There appears to be a white-fld. form of the trade plant.

tomentòsa, A. Rich. Christmas-Tree of New Zeal., because of its season of bloom, intro. into S. Calif. many years ago and now offered by nurserymen: much-branched tree to 70 ft., the short trunk becoming 5 ft. in diam.: lvs. very variable, 1–4 in. long, lanceolate to broad-oblong, acute or obtuse, very thick, usually tomentose beneath: fls. large, dark crimson, in many-fld. terminal cymes, the pedicels and calyces tomentose; stamens numerous, to 1½ in. long. J.F. 2:146.—Cheeseman reports it as a "noble and picturesque tree," abundant in the N. Island of New Zeal.

AA. *Fls. yellowish red; stamens red.*

flórida, Smith. "Usually a tall woody climber," writes Cheeseman in the New Zeal. Flora, "reaching the tops of lofty trees:" lvs. opposite, elliptic-oblong, obtuse, veiny, glabrous: fls. yellowish red or orange-red in few-fld. or many-fld. simple or branched cymes; petals orbicular; stamens scarlet, very numerous, to 1 in. long.—The typical form is not advertised, but only var. **variegàta**, Hort.

M. floribúnda, Hort.=Callistemon lanceolatus.—*M. lùcida*, A. Rich., Mountain Rata, is slightly in cult. in England in an amateur way; usually a tall erect tree in New Zeal., but often a bush in subalpine or exposed places: lvs. elliptic-lanceolate or lanceolate, acuminate, very coriaceous: fls. bright crimson, in broad cymes; calyx-lobes 5, ovate and obtuse; petals oblong, surpassing the calyx-lobes; stamens numerous, 1 in. long. G. C. III. 55:450. G. 36:607.—*M. scándens*, Soland. (M. buxifolia, A. Cunn.), Aka, is a tall woody climber of New Zeal., with distichous, sessile, small, broadly ovate or orbicular, obtuse very coriaceous lvs. and small white fls. in 3-fld. cymes; stamens slender, ⅛in. long. J. F. 1:24.

Wilhelm Miller.
L. H. B.†

METRÓXYLON (*heart wood*, in allusion to the large pith). *Palmàceæ*. Sago Palm. A half-dozen or more species of erect monocarpic (fruiting but once) palms of the Malayan Archipelago, New Guinea and Fiji, mostly or often unarmed, ringed below, with pinnatisect lvs., allied to Raphia. Lvs. terminal, suberect, equally pinnatisect, the segms. opposite and linear-lanceolate-acuminate: spadix large, loosely paniculate: fls. polygamous-monœcious or perfect; corolla 3-parted, the lobes oblong; stamens 6, the filaments connate at base; ovary imperfectly 3-celled, the ovules 3: fr. subglobose or ellipsoid, 1-celled and 1-seeded.—The species and synonymy are confused. None, apparently, is in cult. within our territory. The sago of commerce is derived from the trunks of *M. læve* and *M. Rumphii*. The trunks are cut into lengths, split, and the starch washed out and subsequently heated. These grow in the Malay Isls.

METTERNÍCHIA (Prince Metternich, 1772–1859, Austria). *Solanàceæ*. Probably less than a half-dozen glabrous showy-fld. trees or shrubs of the American tropics, little known in cult. and none of which appears to be in the trade: lvs. entire, shining: fls. solitary or clustered at the ends of the branches, white or rose-red to yellowish; corolla funnelform, tube enlarging above, the limb with 5 or 6 broad lobes; stamens 5, affixed in the base of the corolla, included or somewhat exserted; ovary sessile, 2-celled, the style filiform: caps. narrow, 4-valved. *M. Wércklei*, Schum., Costa Rica, is recently recorded in horticultural literature: sarmentose evergreen shrub, with edible tuberous rootstock, sometimes epiphytic: lvs. ovate: fls. in terminal corymbs, like gloxinia in form, corolla 3 in. long and 2 in. across, fragrant, white changing to sulfur-yellow.

L. H. B.

MÈUM (an old Greek name). *Umbelliferæ*. Spignel. One perennial herb, differing botanically from Ligusticum mostly in technical characters of fr., sometimes cult. for the ornamental delicate foliage. **M. athamánticum**, Jacq. (*Athamánta Mèum*, Linn.), of mountains in Eu., a glabrous tufted aromatic plant with sts. 1–2 ft.: lvs. mostly radical (cauline lvs. very few, small and less divided), pinnately decompound, the segms. multifid and wide-spreading: fls. white, whitish yellow, or pink, in many-rayed terminal compound umbels of medium size; petals acute, narrowed at base, entire but usually with an incurved point; bracts of involucre few and narrow: fr. ⅓in. long, not beaked, the carpels with 5 prominent ribs. The rootstock is said sometimes to be eaten. Prop. by seeds and division.

L. H. B.

MEXICAN TEA: *Chenopodium.*

MEYÈNIA: *Thunbergia.*

MEZERÈUM: *Daphne Mezereum.*

MEZONEÙRUM (Greek *meizos*, stronger, and *neuron*, nerve; referring to the strongly developed, winged upper suture of the pod). *Leguminòsæ*. A group of about 10 species of large usually armed and often climbing shrubs or rarely trees from S. Asia, Afr. and Australasia, closely related to Cæsalpinia, from which it differs chiefly in its compressed indehiscent pod winged at the upper suture and the short very oblique calyx-tube with the lowest lobe enlarged and concave or all lobes connate into a tube. They can be grown only in tropical or subtropical regions. Only the following species is in cult. **M. kauaiénse**, Hillebrand (*Cæsalpínia kavaiénsis*, Mann. *C. kauahiénsis*, Hort.). Tall shrub, to 12 ft., with spreading unarmed branches pubescent while young: lvs. bipinnate, with 2–10 pinnæ, each with 9–17 oblong, obtuse and retuse lfts. about 1 in. long: fls. pinkish purple, in terminal dense racemes; calyx pinkish, glabrous, with the lowest lobe large and concave; stamens exserted, with hairy filaments: pod oblong-obovate, 3–3½ in. long, with 2–4 seeds. Hawaiian Isls.—Intro. into Calif. in 1907. Called "uhuihi" in Hawaii. For cult. and prop. see *Cæsalpinia.*

Alfred Rehder.

MICHAÙXIA (André Michaux, 1746–1802, French botanist, who lived for ten years in America and wrote much on American plants). *Campanulàceæ*. A half-dozen species of rather coarse-habited biennial (perhaps perennial) herbs from the Levant. Useful for borders.

Michauxia belongs, with Campanula and other genera of garden importance, to a group characterized by having the caps. closed at the top and opening laterally by little holes between the ribs or by small solitary valves. It is distinguished from the other genera of this group by the 8–10-parted corolla with narrow, spreading, finally reflexed lobes and an 8–10-celled ovary. Michauxias are erect plants, hispid or glabrous: lvs. irregularly toothed or lobed, the st.-lvs. few: fls. terminal or growing along the branches, the top ones opening first, peduncled or nearly sessile, white or pale rose.—Only 2 species are known to any extent as cult. plants.

campanuloìdes, L'Her. Lvs. lanceolate in outline; upper ones sessile, acute, almost clasping: calyx with reflexed appendages shorter than the lobes; stamens 8. Asia Minor. B.M. 219. G.C. III. 40:111. G.W. 11, p. 199; 15, p. 595.—It grows 4–5 ft. high, has irregularly toothed, bristly-hairy foliage and large curious drooping fls., white, tinged with purple, wheel-shaped at first, later the parts reflexed. The fl. is parted nearly to the base into 8–10 oblong segms. 1½–2 in. long. This plant is a striking subject for the back of a hardy border. It is easily prop. by seeds (which should be fresh), and likes a well-enriched soil of a light character.

Tchihátcheffii, Fisch. & Heldr. A stately plant, 6–7 ft., stout and erect, simple below: lvs. 6–8 in. long, spreading and deflexed, narrow-oblong, toothed or serrate and sometimes lyrate: fls. white, in an erect cylindric very densely fld. terminal spike; corolla-lobes 8, ovate-lanceolate, the margins fimbriate. Asia Minor. B.M. 7742. Gn. 71, p. 625; 77, p. 486. G.M. 57:594. G. 36:22. G.W. 11, p. 198.—Described as biennial, and also as perennial if well cared for.

Wilhelm Miller.
L. H. B.†

MICHÈLIA (P. A. Micheli, 1679–1737, Florentine botanist). *Magnoliàceæ.* Temperate and tropical trees and shrubs, two of which (*M. fuscata* and *M. Champaca*) are cultivated in the southern states for their handsome magnolia-like foliage and red or pale yellow fragrant flowers.

Differs technically from Magnolia in the fls. mostly axillary rather than terminal, the gynophore (stipe of ovary) long and the ovules usually more than 2 in each carpel: fls. mostly axillary, solitary; sepals and petals similar, 9–15 or more, in 3 or more series; stamens as in Magnolia; carpels in a loose spike; stigma decurrent; ovules 2 or more: fr. a long, loose or crowded spike of leathery carpels, which split down the back; seeds like Magnolia.—Species about a dozen, in Asia.

Only one michelia has attained any prominence in this country. This is *M. fuscata,* one of the most popular garden shrubs in the southern states. It is known as the brown-flowered or banana shrub; also *Magnolia fuscata.* It is shrubby in habit, attains a height of 10 to 15 feet and is perfectly hardy in the middle and lower South. The shining young twigs and petioles are covered with brown tomentum. The flowers are 1 to 1½ inches across, brownish yellow, edged with light carmine, exhaling a strong banana fragrance. The flowering period extends from the end of April until June. Propagate by seeds as stated for *Magnolia grandiflora* (p. 1965), but as seed is somewhat scarce, the better method is from ripened wood cuttings, under glass and with bottom heat. The cuttings should have one or two leaves left, and be cut before very cold weather. It is a very desirable conservatory shrub in northern sections. (P. J. Berckmans.)

A. *Fls. pale yellow.*

Champàca, Linn. A tall tree native of the Himalayas, with pubescent branchlets: lvs. ovate-lanceolate, tapering to a long point, 8–10 in. long, 2½–4 in. broad, shining above, pale and glabrous or puberulous beneath; petiole 1½ in. long: fls. 2 in. across; sepals oblong, acute; petals linear: fr. 3–4 in. long.

compréssa, Sarg. (*Magnòlia compréssa,* Maxim.). Tree, to 40 ft., with smooth dark bark: lvs. oblong or narrow-obovate, narrowing into long petioles, obtuse or short-pointed, entire, coriaceous, lustrous above, 3–4 in. long: fls. fragrant, yellow, about 1 in. across; sepals and petals narrow-obovate; anthers nearly sessile; head of pistils stipitate: fr.-cone 2 in. long. Japan, a northern species. G.F. 6:77.

AA. *Fls. brownish.*

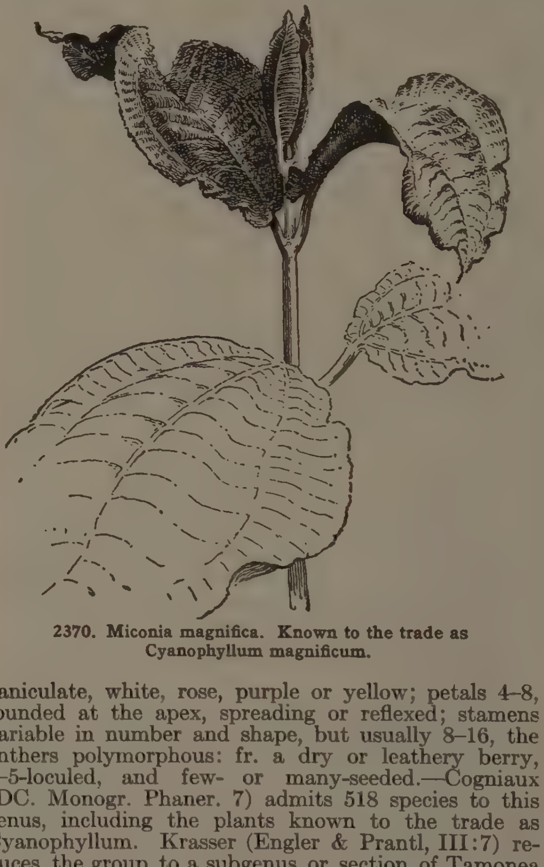
fuscàta, Blume (*Magnòlia fuscàta,* Andr.). Young growths brown-pubescent: lvs. elliptic-lanceolate or elliptic-oblong, smooth at maturity: fls. small, erect, brown-purple, very fragrant; none of the sepals or petals linear. China. B.M. 1008.

L. H. B.†

MICHOLÍTZIA ("sent home by Micholitz when collecting in India and Burma"). *Asclepiadàceæ.* A genus founded in 1909 by N. E. Brown, allied to Marsdenia but differing in the calyx-lobes being valvate and the corona-lobes tubercle-formed and spreading. The single species, *M. obcordàta,* N. E. Br., from India, is said to possess no horticultural value. It is a small undershrub with milky juice, rather small obcordate or obovate lvs. and small fls. with olive-green tube and reddish lobes.

MICÒNIA (D. Micon, Spanish physician). *Melastomàceæ.* Glasshouse subjects, notable for the handsome foliage.

A Trop. American genus of trees and shrubs, with large and showy opposite or verticillate strongly veined lvs.: fls. relatively small, usually corymbose or paniculate, white, rose, purple or yellow; petals 4–8, rounded at the apex, spreading or reflexed; stamens variable in number and shape, but usually 8–16, the anthers polymorphous: fr. a dry or leathery berry, 2–5-loculed, and few- or many-seeded.—Cogniaux (DC. Monogr. Phaner. 7) admits 518 species to this genus, including the plants known to the trade as Cyanophyllum. Krasser (Engler & Prantl, III:7) reduces the group to a subgenus or section of Tamonea (but subsequently restored), the latter genus comprising at that time (1898) about 550 species in Trop. Amer. Many species have been described recently. The most popular of the greenhouse plants, *Cyanophyllum magnificum,* is placed by Cogniaux among the species that are imperfectly known and is not described in the monograph, although it was illustrated and described as long ago as 1859. See *Tamonea.*



2370. Miconia magnifica. Known to the trade as Cyanophyllum magnificum.

The miconias of gardeners are conservatory or warmhouse subjects, grown for their large and striking foliage. They belong to the old genus Cyanophyllum, in which the anthers are subulate and incurved and with a single pore, the flowers large and the calyx oblong or campanulate and truncate or dentate. They propagate by cuttings of the firm wood over bottom heat. The plants should be screened from the direct glare of the sun, and be given abundance of water. Use a fibrous soil. Since the plants are known to gardeners mostly for their foliage, it is probable that some of the trade species are referred to wrong genera. Flowers are not always known when the plants are named. Some of the names have no standing in botanical literature. For culture, see *Melastoma* and *Medinilla.*

magnífica, Triana (*Cyanophýllum magníficum,* Hort.). Fig. 2370. Reaching several feet in height as grown under glass (probably a tree in its native place), robust: lvs. very large (becoming 2–2½ ft. long), broad-ovate and wavy-edged, arched, rugose, upper surface lustrous green, lower surface red, the very prominent veins white or light-colored: fls. small, panicled. Mex. R.H. 1859, p. 359.—Discovered by Ghiesbrecht and first shown by Linden in 1857. One of the best and most striking of all conservatory foliage subjects. Voss (Blumengärtnerei) refers this species to the genus Tamonea and calls it *T. magnifica,* Voss. **M. velùtina,** Lind. & Rod. (I.H. 41:21), of Brazil, is perhaps a form of it; the lvs. are not arched and colors are more bronzy.

spectánda, Rod. (*Cyanophýllum spectándum,* Nichols.). Lvs. oval, 1½ ft. or less long, 6–7 in. broad in the middle, the upper surface dark lustrous green, under side greenish red, the midrib prominent and gray. Brazil.

denticulàta, Naudin (*Melástoma denticulàtum,* Bonpl., not Hort.?). Branches obtusely 4-angled; the young branches, lvs. and calyx furfuraceous: lvs. narrow-ovate, somewhat obtuse, 3-nerved, base rounded, minutely serrulate: fls. pedicillate, aggregated in panicles; petals subrotund, small; calyx somewhat hemispherical. Ecuador. L. H. B.

MICRÁNTHUS (*small flower*). *Acanthàceæ.* Two genera, one iridaceous and one acanthaceous, bear the name Micranthus. The acanthaceous genus now becomes Phaulopsis (or Phaylopsis), which see. The iridaceous genus Micranthus comprises two species from the Cape, allied to Watsonia but differing in the very short tube of the small straight perianth, the fls. in long dense distichous spikes. They appear to be not in regular cult. The species are *M. spicàtus,* Pers., rose-colored, and *M. plantagineus,* Eckl., blue.

MICROCÍTRUS (from the Greek for *small* and *Citrus*). *Rutàceæ,* tribe *Cítreæ.* Small spiny trees or shrubs, closely related to Citrus, but differing in having dimorphic foliage, very small fls., free stamens, very short pistil, few-celled ovary and in the presence of cataphylls in the seedling.

Four species of this new Australian genus (see Swingle in Journ. Wash. Acad. Sci. 5:570) are at present known.

australàsica, Swingle (*Cítrus australàsica,* F. Muell.). Finger-Lime. Spiny shrub or small tree, 15–30 or even 40 ft. in height, native to the mountain scrubs of N. New S. Wales and Queensland: juvenile lvs. very small, oval or ovate, on stiff spreading branchlets; mature lvs. small, obovate, cuneate or rhomboidal, ½–1½ x ½–¾ in.: frs. finger-shaped, 2½–4 x ¾–1 in., smooth-skinned. Ill. Wash. Acad. Sci. 5:572, figs. 1–4.—Young plants of the finger-lime are very ornamental, having successive tiers of horizontal spiny branchlets with juvenile foliage somewhat like a young araucaria. They flower and fruit when but a few years old. The finger-shaped frs. contain a rather disagreeably pungent acid juice. This species is promising for breeding purposes because of its hardiness. It is also promising for use as a hedge plant in warm climates because of its dense spiny branches, dwarf habit, and ability to grow from cuttings. A variety of this species (*M. australàsica* var. *sangúinea*), the red-fruited finger-lime, has blood-red frs. with a pinkish pulp.

Gárrowayi, Swingle (*Cítrus Gárrowayi,* F. M. Bailey.) Garroway's Finger-Lime. Small spiny tree from N. Queensland: juvenile lvs. very small, on stiff spreading branchlets: frs. oval, 2–2½ x 1–1¼ in., rough-skinned, 5-celled.—This species, recently introduced into this country, is very closely related to *M. australasica.*

austràlis, Swingle (*Cítrus austràlis,* Planch.). Dooja. Round-fruited Australian lime, native to the subtropical coastal forests of New S. Wales and Queensland: juvenile lvs. linear, on flexuose branches; mature lvs. ovate or elongate-rhomboidal, 1–2 x ½–¾in.; frs. round, rough-skinned, 1–2½ or even 3 in. diam., 5- (rarely 6- or 7-) celled. Ill. Penzig, Studi s. Agrumi, pl. 21, figs. 8–12.—The dooja is one of the most interesting Australian citrous frs. It reaches a height of 30 to 60 ft. and bears frs. said to reach 2½ or even 3 in. diam. The growing shoots and immature lvs. on plants cult. in the open are of a deep wine-red color. Because of its vigor this species is of interest for use as a stock. It shows considerable resistance to winter cold in Calif.

inodòra, Swingle (*Cítrus inodòra,* F. M. Bailey). The Russell River Lime. A spiny tree, bearing ribbed frs., native to Queensland: lvs. large, 3–7 x 1½–2½ in., lanceolate, not articulated with the petiole which is very short; fls. inodorous: frs. ribbed, 2–2½ x 1¼ in., oval, 8-celled. Ill. Bail. Fl. Queensland, 1, pl. 10, 1899.—The Russell River lime in the wild state bears edible frs. said to equal in flavor the West India lime. This has not yet been intro. into culture. Walter T. Swingle.

MICROCÝCAS (*small cycas*). *Cycadàceæ.* One species in Cuba, differing from Zamia in the character of the floral scales (masculine scales plane and obtuse, the feminine thickened at the apex and truncate); caudex cylindrical, covered with bases of the petioles. *M. calócoma,* A. DC. (*Zàmia calócoma,* Miq.), has a dwarf trunk and lvs. 3 ft. long: lfts. about 80 pairs, long-linear, acuminate, revolute, parallel-nerved: foliage pubescent. Probably not offered.

MICROGLÓSSA (*small tongue,* because the ligules are short). *Compósitæ.* Nine or 10 Asiatic and African shrubs, sometimes climbing, allied to Erigeron and Aster, very little grown: lvs. mostly entire and alternate: fls. in small corymbose or panicled heads with very small white or bluish rays; ray-fls. in 1 to many series, pistillate and fertile; disk-fls. perfect and fertile, with 3–4-toothed dilated limb; involucre of many-rowed narrow bracts, the outer shorter; receptacle flat, nearly or quite naked: achene angled, bearing copious slender pappus-hairs. *M. albéscens,* Clarke (*Áster albéscens,* Wall.), occurs in horticultural literature: erect, with faintly grooved branches: lvs. lanceolate, entire or slightly serrate, hoary beneath: heads ⅓in. diam., with bluish or whitish ligules. Temperate Himalaya. R.H. 1907, p. 523.

MICROKÉNTIA (*small* or *minute Kentia*). *Palmàceæ.* Here may belong the plant known to the trade as *Kentia gracilis.* Microkentia is a genus of 6 species of palms from New Caledonia. They are unarmed, with slender bamboo-like ringed trunks. The lvs. are terminal, pinnatisect, and the lf.-segms. are long-sword-shaped and distinct, or the upper ones grown together into a broad 2-cut blade. The frs. in this genus are amongst the smallest in the palm family. The fls. also are minute. The true kentias, of which perhaps none is cult., have larger fls. and frs., the former white, the latter vermilion. The anthers are fixed at the base in Kentia, but dorsifixed and versatile in Microkentia. Microkentia is nearer Clinostigma and Cyphosperma, but in these the lf.-segms. are irregularly cut off at the apex. *Kentia gracilis,* Brongn. & Gris. =*Microkentia gracilis,* Benth. & Hook. It is possible that the *Kentia gracilis* of the trade is *Kentiopsis divaricata.* None of the other species is known in cult. N. Taylor.†

MICROLÉPIA (Greek, *a small scale;* alluding to the indusium). *Polypodiàceæ.* A genus of graceful greenhouse ferns, allied to Davallia, but having the shallow, half-cup-shaped, membranous indusium attached to the sides as well as the base; the stalks are also continuous with the rootstock, and not joined to them, as in the true davallias.—Twenty or more species are known. For cult., see *Davallia.*

A. *Lvs. once-pinnate.*

marginàta, C. Chr. (*M. marginàlis,* Baker. *M. scàbra,* Hort.). Rootstock creeping: lvs. 18–24 in. long, 9–15 in. wide, with linear pinnæ, which are cut about half-way to the rachis into bluntish, oblong lobes. Ceylon to China.

AA. *Lvs. tri-quadripinnatifid.*

platyphýlla, J. Smith. Rootstock stout, scaly: lvs. 3–4 ft. long, on stout stalks, tripinnatifid; ultimate divisions broad, bluntish, toothed, oblong, deltoid; sori 2–12 to a segm., 1 in each tooth. India to Japan.

hírta, Presl. Lvs. 3–6 ft. long, on stout stalks, tri-quadripinnatifid; ultimate divisions oblong, broadly toothed; rachises hairy or pubescent; sori 2–20 to a segm., 1 or more together at the base of each tooth. India and Polynesia. Var. **cristàta** is also offered by the trade. F. 1878, p. 59. Gn. 31, p. 428. F.R. 1:769.

L. M. Underwood.

MICROLÒMA (*small fringe,* referring to the hairs in the corolla-tube). *Asclepiadàceæ.* Slender-stemmed twining perennials, or sometimes dwarf little shrubs, little known in cult.: lvs. small, opposite: fls. mostly pink or red, in small subaxillary umbel-form cymes: 10 species in S. Afr. *M. tenuifòlium,* Schum., has a cluster of stout fleshy roots, partially herbaceous, glabrous st., linear revolute lvs., urn-shaped somewhat fleshy carmine-red corollas with tube 2½ in. long. B.M. 8248.

MICROMÈLES: *Sorbus.*

MICROMÈLUM (from the Greek for *small* and *apple*). *Rutàceæ.* Small spineless trees or shrubs distantly related to Citrus, of interest for breeding experiments and trial as stocks.

Leaves odd-pinnate; lfts. 3–9, alternate, ovate or obtusely acuminate: infl. a many-fld. terminal cyme or corymb; fls. 4–5-parted: fr. small, like a large pea, 5-celled with 1–2 ovules in each cell. The genus ranges from Indo-China throughout India and the Malay Archipelago, and includes several species. They should be intro. into the U. S. for trial in breeding experiments.

Walter T. Swingle.

MICROMÉRIA (*small part;* small-flowered). *Labiàtæ.* Small more or less trailing or decumbent perennial herbs and subshrubs, sometimes planted in borders and rock-gardens.

Leaves usually small, entire or toothed: whorls axillary or in terminal spikes; fls. small; calyx tubular and mostly 13-nerved, 5-toothed, somewhat 2-lipped; corolla 2-lipped, upper lip erect, flattish, entire or notched, lower spreading, 3-lobed; stamens 4, didynamous; style 2-parted at apex: nutlets smooth, ovoid or oblong.—Species 60 or more in northern extra-tropical countries, particularly in the Medit. region. By some authorities, the genus is included in Satureia. Of simple cultural requirements. Prop. by division as well as by seeds.

A. *Fls. few in the axils.*

Chamissònis, Greene (*M. Doúglasii,* Benth. *Thýmus Chamissònis,* Benth.). Yerba Buena. Perennial: sts. long, slender, trailing and creeping, with sweet-scented round or oval lvs., 1 in. or less across: fls. purplish, mostly solitary in the axils, on long 2-bracted pedicels. Woodlands, from Vancouver Isl. to S. Calif.—Sandy soil. Roots by stolons.

Piperélla, Benth. (*Thýmus Piperélla,* All.). Fig. 2371. A few inches high, with slender arching branches: lvs. ovate, more or less cordate, sessile: fls. purple-and-white in few-fld. lax peduncled secund fascicles; corolla lightly pubescent. S. Eu.—A partially shrubby rock-garden plant; prop. by cuttings.

AA. *Fls. numerous in the axils.*

2371. Micromeria Piperella. (Flower ×½)

rupéstris, Benth. A dense, low-growing perennial, woody at the base, with prostrate sts., which turn up at the extremities, giving a heath-like effect when in bloom: lvs. with the odor and taste of pennyroyal: fls. abundant, small, white, with lavender spots on the inner side of corolla-lobes, borne for several inches along the sts. S. Eu.—Prop. from cuttings and seeds. It blooms from July until heavy frosts, and proves very satisfactory for rockery and informal border.

L. H. B.†

MICROPHŒNIX (*small Phœnix*). *Palmàceæ.* A name applied to two hybrid palms that were described some thirty years ago. *M. decípiens,* Naudin, is a hybrid between *Phœnix dactylifera* and *Chamærops humilis;* and *M. Sahùtii,* Carr., between the foregoing (*M. decipiens*) and *Trachycarpus excelsus,* with the violet-colored petioles and fruit of the latter parent. R.H. 1885. p. 513.

MICROSPÉRMA: *Eucnide.*

MICRÓSTYLIS (Greek, *small style*). Syn., *Achroánthus. Orchidàceæ.* Mostly terrestrial orchids, sometimes grown under glass, and the hardy kinds perhaps transplanted to the bog-garden; some of the exotic species have colored foliage.

Deciduous, low plants, with fleshy roots, solid bulbs, or some of the kinds with pseudobulbs: lvs. plicate or membranaceous (in some species only 1): fls. mostly small, usually greenish or yellowish but often oddly shaped, in a terminal raceme, spike or umbel, with small and narrow bracts; sepals free, spreading and nearly equal; petals about the length of the sepals but very narrow or even filiform; lip sessile and erect or spreading, shorter than petals but often very broad, entire or fimbriate or 2–3-lobed, cordate or ovate or auricled at base; pollinia 4, in pairs: fr. a small ovoid beakless caps.—Species more than 100, in many parts of the world, largely in the North Temperate Zone and some of them tropical; a few species occur in the U. S. and Canada. None of the species seems to be regularly in the American trade, but a few are offered abroad by orchid specialists.

The species of microstylis are deciduous orchids. They grow well in the warm end of the cattleya department, or better still treated like thunias or calanthes,—a rather warm moist atmosphere when growing in spring, reducing the same toward late summer as they begin to lose their foliage, and eventually resting them quite dry in a temperature of about 60° F. during winter. They will probably suffer in a Wardian case or bell-glass. They certainly will after growth is completed, if not at all times. (Robert M. Grey.)

M. calophýlla, Reichb. f. 9 in.: fls. yellowish: lvs. ovate, undulate, spotted green, greenish brown in center and the margin gray-green: pseudobulb conical. Malaya.—*M. congésta,* Reichb. f. (M. Bernaysii, F. Muell. M. fusca, Reichb. f.). One foot: fls. greenish yellow, in a dense cylindrical raceme or spike: lvs. green.

Trop. Asia.—*M. díscolor*, Lindl. 9 in.: fls. handsome but very small, yellow, shading to orange, on upright stalks: lvs. red-purple, bordered green. Ceylon. B.M. 5403.—*M. Josephiàna*, Reichb. f. 1 ft.: fls. yellow, rather large, in a raceme: lvs. broad-ovate, bronze, light green below: pseudobulbs oblong. India. B.M. 6325.—*M. macrochìla*, Rolfe. 15 in.: fls. rather large, the sepals and petals yellow and lip red-purple and veined: lvs. mottled with light brown and cream. Farther India.—*M. metállica*, Reichb. f. 9 in.: fls. rose-purple, with sepals marked yellow: lvs. oblong, acute, dark glossy purple with metallic sheen, light rose underneath: pseudobulbs cylindrical. Borneo.—*M. philippinénsis*, Kränzl. Fls. yellow or purplish, sometimes as many as 100 in a spike 8 in. or more long; lip orbicular, deeply cordate at base: lvs. broad-oblong, somewhat undulate, bright green. Philippines.—*M. purpùrea*, Lindl. 9 in: fls. yellow-purple: lvs. dark metallic crimson above and red-gray beneath. Ceylon.—*M. Scóttii*, Hook. f. 6 in.: fls. yellow: lvs. light green and cream-colored, on the margin and along the rib mottled light brown. Farther India. B.M. 7268.—*M. Wállichii*, Lindl. (M. biloba, Lindl.). 9 in.: fls. green-yellow to purplish: lvs. green, more or less shaded purple. Burma.

L. H. B.

MIGNONETTE (*Reseda odorata*) is a branching, annual herb from northern Africa, which at first grows upright, but later becomes more or less decumbent and wide-spreading. The leaves are simple. The fragrant small yellow-and-white flowers are borne on spicate racemes which vary in size with different strains of seed. (Fig. 2372.)

Although mignonette has been grown under glass for many years, it is only recently that growers have specialized with this crop for winter forcing. Careful selection of seed has resulted in greatly improved strains. Formerly the mignonette spikes were scattered and comparatively small; now large spikes of dense flowers are being produced. The sprays are very pleasing when arranged with carnations or other flowers having scanty foliage. The fragrance of the flowers adds to their popularity. The demand for mignonette has so increased the importance of the crop commercially that many florists are specializing in its cultivation.

Mignonette will grow in almost any soil, but the large growers prefer a medium light turfy loam. Pasture sod is excellent, and sod from a field which has been in grass for a considerable time is also good. William Nicholson of Framingham, Massachusetts, has been exceptionally successful in growing mignonette, and from his cultural notes have been compiled the following directions:

In growing good mignonette, a well-prepared soil is of prime importance. The same kind of soil is used as for carnations, and is prepared by first plowing the sod-land after the grass has been cut, usually about the first of August. After plowing, the wheel-harrow is used, and then rye and Canadian white field peas are sown. The last of October or the first of November, a heavy top-dressing of cow- or horse-manure is applied. Cow-manure is preferable. This is plowed under and left until spring. As soon as it is possible to work the ground, the land is wheel-harrowed several times, and an application of manure is made. The soil is plowed again, well disked, and bone-meal applied, about one ton to the acre; the land is then ridged, and is ready for the benches. This method of preparation eliminates much hand work, and there is little danger of the soil becoming sour, as it frequently does if the compost method is practised.

Most growers prefer to grow mignonette in raised benches about 5 inches deep. An inch of well-rotted stable-manure is placed on the bottom of the bench, and the remainder is filled with the composted loam.

The surface of the soil is leveled carefully, and marked off in rows 6 by 8 inches apart. From six to ten seeds are dropped at the intersection of each row, and covered very lightly. A light watering with a fine sprinkler is then given the soil, to settle it around the seeds.

Three sowings of seed are made each year,—in the first weeks of July, August, and September. Plants of the last sowing flower until the next July. After the seeds have germinated, and the seedlings have developed the third leaf, three strong plants are selected and the others removed. Seed for next season's crop is selected from the plants started in September. The plants which produce good foliage and compact flower-spikes, with large individual flowers, are selected as the seed-bearing parents.

Great care should be taken that the seedlings started in July receive sufficient air. The ventilators should be kept open day and night to keep the plants stocky and short-jointed. During bright weather, temporary shading is necessary in the middle of the day, until the seedlings get their second leaf, then full sunlight should be given. After the flower-spikes begin to appear, all side shoots should be removed from around the top of the stem. Three or four strong bottom side shoots are left for a second crop. In this way a succession of blooms may be obtained throughout the winter. As soon as the plants are well developed, a wire ring is placed about each plant. Later, wires with cross strings are used for supports, the same as are used for carnations.

Mignonette is injured by over-watering, and great care should be taken that the soil be not too wet, especially when the plants are just started. As they develop, watering should be done only on bright mornings, for if water remains long on the foliage, the leaves become spotted.

2372. Mignonette, Allen's Defiance.

A night temperature of 45° to 48° best suits mignonette. On cloudy days the temperature should be kept at 55°, and on bright days it should never be allowed to go above 65°.

When the plants have developed sufficiently so that flower-spikes are forming, they will require additional food. It is composed of one part sheep-manure and two parts of loam The two are thoroughly mixed and three large handfuls of the mixture are scattered about the plants in a row across a 3-foot bench. Instead of this top-dressing, they may be given a weak solution of liquid manure. A bushel of sheep-manure is put into a bag and suspended in a barrel of water for two or three days. The bag is then removed, and the plants watered with the liquid.

Mignonette is grown in pots to a limited extent. There is some demand for it at Christmas and Easter, and some florists always have pot-plants in stock. It is more difficult to grow in pots than in beds, as it is necessary to have compact, stocky plants. This requires a great deal of care. The best method of culture is to fill 2½-inch pots with finely sifted soil, which has been prepared the same as described for bench culture, and to sow the seed in this soil. It should be remembered that the mignonette will not transplant; therefore, the seeds should be sown exactly where the plants are to grow. Several seeds should be sown in each pot to insure a perfect germination, and after this has taken place and the plants are well developed, all but one plant should be removed. The young plants should be kept as near the glass as possible to foster a stocky growth. Great care should be taken not to let the plants dry out, neither should they be over-watered.

As soon as the soil is filled with the feeding-roots, the plants should be re-potted, and this re-potting should be done frequently, the plants never being allowed to become pot-bound. When the plants are from 4 to 5 inches tall, they should be pinched, and the side shoots allowed to develop. When they have grown to a height of 6 or 7 inches, they should be staked and tied, and again pinched back to encourage branching. The large flower-spikes are not desired in pot-grown plants, but a larger number of smaller spikes. Pinching makes the plants much more symmetrical. When the plants are in flower, they should be in 7- or 8-inch pots.

As a garden flower, the mignonette is by no means showy, but its delicate fragrance makes it popular. It requires a cool well-drained soil, and one which is moderately rich in decayed organic matter. It does not like the full sunlight, so should be given a spot which is shaded a part of the day. The seed should be sown late in April, in the North, and a second sowing may be made early in July, so that the season of bloom be extended until the time of severe frosts.

E. A. White.

MIKÀNIA (Prof. J. G. Mikan, of Prague, or his son and successor, J. C. Mikan, who collected in Brazil). Syn., *Willugbæya. Compósitæ.* Shrubs or herbs, the latter twining, rarely erect.

Leaves opposite, usually stalked: heads spicate, racemose, corymbose or panicled; fls. mostly white or pinkish.—About 150 species, mostly found in the warmer parts of Amer. Nearest to Eupatorium, but the latter has an indefinite number of involucral bracts instead of 4, and contains erect plants. This includes *M. scandens*, the climbing hempweed, a common native weed, but a pretty one.

scándens, Willd. Climbing Hempweed. Foliage distinct, the lvs. being somewhat heart-shaped or halberd-shaped, and long-acuminate: fls. very small, numerous, pinkish, and borne in dense clusters 1–2 in. across; these clusters, as in all the species, are composed of many small heads, each containing 4 fls., surrounded by an involucre of 4 bracts. Moist ground, New England to Fla. and Texas.—Very rarely offered by dealers in native plants.

Sánderi, Hort. Hothouse climber, with variegated foliage. Intro. 1899 by Sander & Co., who say the lvs. are richly embellished with dark velvet-purple patches; veins of mature lvs. white. The lvs. are about 6 in. long, 5 in. wide, boldly toothed. The botanical affinities of this plant are uncertain.

N. Taylor.†

MILDEW is the name given to a group of fungous diseases which attack leaves, shoots, flowers and fruits. The true or powdery mildews (Erysiphaceæ) appear as a thin white powdery coating on the surface of the plants. The disease is usually accompanied by distortion and dwarfing, and often death of the affected parts. In some cases, however, as in the maple mildew, the affected areas of the leaves retain their chlorophyll and remain green in the autumn long after the remainder of the leaf is dead and yellow. The mycelium is always superficial, forming spots or more or less extended areas on the affected organs. The injury is done by numerous haustoria, which penetrate the cells of the host and absorb nutriment for the mycelium, and also serve as organs of attachment. During the summer mildews are propagated by 1-celled spores, many of which are cut off in succession from erect simple branches all over the diseased surface. Other spores, by means of which the fungus passes through the winter, are produced in sacs inclosed within hollow spherical receptacles, called perithecia. These appear as minute black or dark brown specks over the diseased area. They are produced in the autumn, and remain on the fallen leaves; but the spores within them do not ripen until the following spring, when they are liberated by the decay of the perithecia.

In the United States, considerable injury is caused by the following species: The rose mildew, *Sphærotheca pannosa*, on roses under glass; *Erysiphe graminis* on wheat and other grasses; the vine mildew, *Uncinula spiralis*, producing the powdery mildew of grapes; *Podosphæra Oxycanthæ* on apples and pears; and *Sphærotheca Castagnei*, the hop mildew. The most successful mode of combating the mildews is by dusting with sulfur or spraying with bordeaux mixture. Either of these fungicides kills the mycelium and spores of the fungus

The downy mildews or false mildews belong to the Peronosporaceæ, a group of fungi widely separated from the true mildews. The mycelium is parasitic within the tissues of the host, only the fruiting branches appearing at the surface. The fruiting branches have a characteristic form and method of ramification for each genus of the group. The spores, when they lodge on new host-plants, either produce an infecting thread directly, or, in most cases, the content of the spore is discharged in the form of swarm-spores, which swim about for a time and finally come to rest and produce the infecting mycelium. Resting-spores are produced sexually in this group within the tissues of the host.

This family contains about ten genera, of which the following are most commonly known: *Phytophthora infestans*, the potato blight; *Plasmopara viticola*, the downy mildew of grapes; *Bremia lactucæ*, often causing great damage to lettuce in forcing-houses; *Pythium Debaryanum*, causing damping-off of seedling cucumbers and various other seedling plants; and *Cystopus candidus*, the common white rust of crucifers. Modes of combating these diseases are set forth for each specific case in the experiment station literature of the various states. See, also, *Diseases and Insects*.

Heinrich Hasselbring.

MÍLIUM (ancient Latin name of broom-corn millet which, however, belongs to a different genus). *Gramíneæ.* Millet-Grass. Spikelets 1-fld., in diffuse panicles: glumes awnless, the lemma and palea coriaceous, as in Panicum.—Contains 5 or 6 species distributed through Temp. Eu. and Asia, one of which, *M. effusum*, also found in N. Amer., is occasionally cult. for ornament.

effùsum, Linn. A smooth woodland perennial, 3–6 ft. high: lvs. broad and thin: panicle 6–9 in. long, with slender drooping branches. Dept. Agric., Div. Agrost. 7:104.

A. S. Hitchcock.

MILK PEA: *Galactia.*

MILK VETCH: *Astragalus.*

MILKWEED: *Asclepias.*

MILKWORT: *Polygala.*

MÍLLA (J. Milla was head gardener at the Court of Madrid). *Liliàceæ.* An attractive spring-flowering bulb.

Leaves few, very narrow, grass-like, radical: scape low, simple and leafless, bearing 1 to several fls. in a terminal umbel; perianth salverform with 3-nerved segms. which are separate nearly to the base; stamens 6, nearly sessile in one row: caps. sessile, oblong-obovate. Bentham & Hooker, as well as Engler, restrict the genus

Milla (as Cavanilles, its author, intended) to one Mexican species. From Brodiæa the genus differs in the fact that the pedicels are not jointed and the perianth-segms. are always 3-nerved. Milla and Brodiæa are native to the northern half of the western hemisphere. In S. Amer. is the genus Triteleia, which is by some referred to Milla, by others to Brodiæa, and by still others kept distinct. There is one Triteleia (*T. uniflora*) in common cult. In his monograph (Journ. Linn. Soc. 11, p. 378), Baker refers the triteleias to Milla, and this disposition is followed by Index Kewensis, but in a later account (G.C. III. 20, p. 459) he refers them to Brodiæa. Watson (Proc. Amer. Acad. Arts & Sci. 9, p. 240) restricts Milla to one species. The N. American plants which have been referred to Triteleia are perhaps best treated as brodiæas, and they are so considered in the account of that genus in Vol. I of this work (p. 576). The S. American triteleias are described under that genus in Vol. VI.

biflòra, Cav. Scape 6–18 in. high from a small coated bulb, bearing 1–5 (usually 2) star-like, waxy white, fragrant fls. 2–2½ in. across, with oblong-lanceolate segms.: lvs. rough, nearly terete. S. Ariz. and New Mex. to Cent. Mex. B.R. 1555. F.S. 14:1459. Gn. 24, p. 155. J.H. III. 55:133. G. 6:271.—One of the best of the small bulbs. It is known as Mexican star, Mexican star of Bethlehem, frost flower, and floating star. The fls. are of a charming waxy consistence, and are borne on long sts. They are excellent for cutting, and last several days. Planted in the border early in spring, they soon throw up their fls. and lvs. They should be allowed to remain until Sept. or Oct., when they may be taken up and stored for the winter. Our gardeners know milla mostly as a pot bulb for flowering under glass late in winter or early in spring. It blooms readily in the conditions given to freesias. Several bulbs should be placed in a pot, although a number of stalks will spring from one bulb. The plant is little offered by dealers. L. H. B.

MILLER, DUSTY: *Lychnis Coronaria;* also *Senecio* and *Artemisia.*

MILLETS are important agricultural grasses. The true millet or **Broom-corn millet** of Europe is *Panicum miliaceum.* The common millets of the United States, the **Foxtail millets,** are forms of *Setaria italica.* **African millet,** also called Black, Chinese, Indian, and improperly Pearl millet, is *Holcus Sorghum.* The name African millet is sometimes applied to *Eleusine Coracana.* **Barnyard** or **Japanese millet** is *Echinochloa frumentacea.* **Pearl millet** is *Pennisetum americanum.* Dept. Agric., Farmer's Bull. No. 101 is devoted to foxtail millets. A. S. Hitchcock.

MILLÉTTIA (named in honor of Dr. J. A. Millett, botanist, and who wrote on China in 1726). *Leguminòsæ.* About 100 or so species of Old World tropical trees and large shrubs, usually climbers; differs from the Japanese and N. American genus Wistaria in the hard usually flat and thick pod not opening so readily: lvs. large, odd-pinnate; lfts. opposite, stipellate: fls. showy, in axillary racemes often fascicled, simple or paniculate and terminal, white, purple or reddish.—Although an abundant genus in Trop. Afr. and the far E., it has yielded little for American horticulture.

A. *Fls. purple.*

cáffra, Meissn. Ironwood. A S. African tree, 20–30 ft. high, with very hard close-grained brown wood and dark, rough, rugulose bark: lvs. on channeled petioles 6–8 in. long; lfts. lanceolate-oblong, acute, in 5–6 pairs, 2–2½ in. long, 1 in. apart; slender stipules 2–3 lines long: panicle 6–8 in. long: fr. leathery, velvety, used as a medicine by the Kafirs. Intro. into Fla. in 1891.

AA. *Fls. white.*

japónica, Gray. A Japanese woody climber: lvs. light green, odd-pinnate; lfts. narrowly ovate, 4–6 pairs, 1½ in. long, 1 in. apart: racemes simple, nodding, 5–8 in. long. Probably not hardy in the N. Has been offered by dealers in Japanese plants. S.Z. 1:43 (*Wistaria japonica*).—At the Arnold Arboretum (Boston) it kills to ground but comes up in spring, not blooming; on Long Island, it blooms and even fruits. L. H. B.

MILTÒNIA (named for Lord Fitzwilliam, Viscount Milton, a patron of horticulture). *Orchidàceæ.* Some of the most beautiful orchids in cultivation, with pseudobulbs closely clustered and sheathed with long graceful dark green leaves, forming plants over 1 foot in diameter, bearing numerous large flowers.

Herbs, with short pseudobulbs, bearing 1–2 lvs. at the summit and few or many sheathing lvs. at the base: the infl. arises from the base of the pseudobulbs, and consists of a single-fld. peduncle or of a loose raceme of long-pedicelled fls.; sepals sub-equal, spreading, free or the lateral ones slightly united; petals similar or a little wider; labellum not distinctly clawed, large, expanded, not 3-lobed, but often bifid at the apex; both the segms. and the labellum are expanded, forming a flat fl.; column short.—About 20 species, mostly from Brazil. *M. Roezlii, M. vexillaria,* and some closely related kinds were until recently known in gardens as odontoglossums. In the group containing the "true" miltonias, the pseudobulbs are separated from each other on the rhizome, and bear 1–2 yellowish green lvs. at the summit and few sheathing lvs. of the same color at the base. The fls. of nearly all miltonias remain on the plants in a fresh condition for a month or more. The leading species run into many horticultural forms listed under Latin names.

KEY TO THE SPECIES.

A. *Pseudobulbs crowded, with numerous dark or gray-green sheathing lvs. at the base.*
  B. *Labellum sagittate at the base* .... 1. **Roezlii**
    2. **vexillaria**
  BB. *Labellum not sagittate, constricted in middle, (broadly panduriform)* ... 3. **Endresii**
    4. **Phalænopsis**
AA. *Pseudobulbs situated at intervals on the rhizome, with few yellowish green lvs.*
  B. *Segms. of perianth broad, ovate to oblong.*
    C. *Perianth uniformly colored white, rose or purple* .... 5. **spectabilis**
      6. **Regnellii**
    CC. *Perianth variegated, yellow and brown or brown and green.*
      D. *Labellum fiddle-shaped* .... 7. **Clowesii**
      DD. *Labellum broadly obovate* ...... 8. **candida**
        9. **cuneata**
      DDD. *Labellum oblong* ....10. **Warscewiczii**
        11. **Russelliana**
  BB. *Segms. of perianth linear-lanceolate*..12. **flavescens**

1. **Roèzlii,** Nichols. (*Odontoglóssum Roèzlii,* Reichb. f.). Pseudobulbs narrowly ovate, 1–2 in. long: lvs. numerous, slender, 8–12 in. long, narrowly linear-lanceolate: scapes about half as long as the lvs., bearing 2–3 large fls.; fls. flat, 3–3½ in. across, pure white, with a purple band at the base of the petals and a yellow stain, more or less marked with reddish brown

at the base of the labellum; sepals and petals ovate-oblong, acute; labellum large, broadly obcordate, with a tooth in the sinus, and a spur-like horn projecting backward on each side of the column. Closely allied to *M. vexillaria*, from which it differs in color and by the more slender, nerved lvs. Flowers twice a year in winter and spring. Colombia. B.M. 6085. I.H. 23:228. R.H. 1875:450. Gn. 4, p. 251; 10:106; 26:232. G.C. III. 32:135. Var. **álba,** Hort. (*Odontoglóssum Roézlii* var. *álbum*). Fls. large, lacking the purple band on the petals. Gn. 26: 232. F.M. 1875:164. A.F. 13:1453. Gng. 6:327.

2. **vexillària,** Nichols. (*Odontoglóssum vexillàrium,* Reichb. f.). Fig. 2373. Pseudobulbs 1½–2 in. long: lvs. 6–12 in. long, narrowly elliptic-lanceolate: scapes sometimes 6 from a single pseudobulb, slender, and longer than the lvs., 3–4-fld.; fls. the largest of the genus, flat, about 4 in. long; sepals and petals ovate-oblong or obovate, pale or dark rose, sometimes with white margins; labellum large, rounded, deeply emarginate, narrowed to a sagittate claw, deep rose, whitish at the base, streaked with yellow and red. The fls. are extremely variable in shape and color. Spring and early summer. Western slope of the Andes, Colombia. B.M. 6037. I.H. 20:113. F.S. 20:2058. R.H. 1876:390. Gn. 9, p. 577; 10, p. 108; 17:474; 35, p. 268; 45, p. 536. G.C. II. 26:145; III. 18:743; 19:755; 27: suppl. May 26; 42:406; 44: 184. J.H. III. 31:301. G.F. 8:195. G. M. 39:386. G.Z. 21, p. 241. V. 5:138. A.F. 13:121.—One of the most popular of all orchids. Var. **Cobbiàna,** Hort. Sepals and petals light rose, passing into white margin; lip white with 3 basal small yellow lines. Vars. **gigantèa, grandiflòra, pícta, ròsea,** have been advertised under Odontoglossum. Many forms are mentioned and described in horticultural literature; for these, the reader should consult the lists of orchid specialists.

2373. Miltonia vexillaria.

3. **Éndresii,** Nichols. (*Odontoglóssum Warscewíczii,* Reichb. f.). Pseudobulbs small, tufted: lvs. numerous, distichous, elliptic-lanceolate, about 1 ft. long: scape as long as the lvs., inclined or drooping, 6–8-fld.; fls. 2–2½ in. diam., flat, white, with a yellow crest on the labellum and a rose-colored blotch at the base of each segm.; sepals broadly ovate; petals elliptic; labellum very broadly fiddle-shaped and 2-lobed. Feb. Costa Rica. B.M. 6163.

4. **Phalænópsis,** Nichols. (*Odontoglóssum Phalænópsis,* Lind. & Reichb. f.). Pseudobulbs ovate, with grass-like lvs. 8–10 in. long at the base and apex: stalks 1–3-fld., shorter than the lvs.: fls. large, flat, white, with the labellum variegated and streaked with crimson; sepals 1 in. long, oblong, pointed; petals broader and rounded; labellum large, broadened and 2-lobed in front, constricted near the middle and expanded above into 2 rounded lobes. The pseudobulbs are clustered, forming clumps 1 ft. or more across, with numerous fls. mingled with the long, grass-like lvs. Spring and summer. Colombia. I.H. 3:109. Gn. 18, p. 447; 26, p. 232; 35, p. 269; 36, p. 315. G.C. II. 25:364. I.H. 28: 417 (var. *luxurians,* more vivid). Var. **álba,** Hort. Fls. pure white except yellow markings on lip.

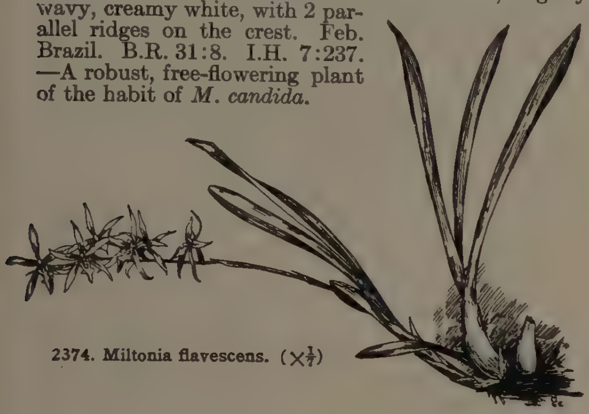
5. **spectábilis,** Lindl. Rhizome creeping, with the pseudobulbs placed about 1 in. apart, with 2 lvs. at the apex and few sheathing lvs. at the base: lvs. linear-oblong, 4–12 in. long: scapes erect, sheathed, 6–8 in. long, bearing a single fl. about 4 in. diam.; sepals and petals oblong, obtuse, slightly waved, white or cream-colored; labellum 2 in. long, very broad in front, pendent, somewhat undulate, rose-purple, with darker veins. Brazil. B.M. 4204. B.R. 1992. I.H. 6:216; 12:446 (var. *cereola*); 14:524 (var. *rosea*); 15:573 (var. *virginalis*). P.M. 7:97. F.C. 1:45 (*Macrochilus Fryanus*). R.B. 15:25. G.M. 38:642. A.F. 6:631.—The first miltonia intro. into cult. It blossoms in autumn, large plants bearing from 20–50 fls., all opening at once and lasting about a month. Var. **bícolor,** Hort. Fls. white, with a violet spot on the labellum. Large-fld. and vigorous. Aug. Var. **Moreliàna,** Hort. (*M. Moreliàna,* Hort.). This variety is very distinct in color. Sepals and petals deep purple; labellum of the same color, veined and shaded with rose. In habit the plant is like the type in every detail. B.M. 4425 (as var. *purpureo-violacea,* Hook.). F.S. 10:1008. I.H. 2:71. Gn. 31:374 (habit poor). F.M. 1874: 143. G.M. 40:37. F. 1850, p. 123 (outline). A.F. 6:633.

6. **Régnellii,** Reichb. f. Like *M. candida* in habit and foliage: lvs. 1 in. broad: scapes erect, bearing several large fls. over 2 in. diam.; sepals and petals spreading, recurved at the apex, oblong, acute, white; labellum subpandurate, obtuse or emarginate, rose-purple, with deeper veins and 3 yellow keels at the base. Sept. Brazil. B.M. 5436. Var. **purpùrea,** Pynaert. Sepals and petals tinted with rose, with white margins; labellum crimson, with a white crest. R.B. 17:253.

7. **Clówesii,** Lindl. Pseudobulbs ovate-oblong, leafy at the base and bearing 2 narrow ensiform lvs. at the apex: scape erect, 1 ft. long, many-fld.; fls. 3 in. across, orange-yellow, mottled with brown, the lip white with a violet base; sepals and petals spreading, lanceolate, acuminate; labellum fiddle-shaped, with a cordate base and a broadly rotund, acute terminal portion. Resembles *M. candida.* Sept., Oct. Brazil. B.M. 4109. P.M. 9:241. Gt. 5:160. Var. **rosefieldiénsis,** Hort., has very large fls.

8. **cándida,** Lindl. Pseudobulbs ovate-oblong, 2-lvd., with few lvs. at base: lvs. oblong-linear, 1 ft. long, 1½ in. broad: raceme erect, 1 ft. long, 6–8-fld.; sepals and petals spreading, oblong, acute, somewhat wavy, bright yellow, with large red-brown blotches; labellum large, broadly obovate, convolute, crenate and wavy on the margin, white, changing to yellow, with a faint purple blotch. Brazil. B.M. 3793 (var. *flavescens*). P.M. 6:241. Gn. 20, p. 463.—A strange species producing 5–6 racemes, each with 6–10 fls. about 2½ in. across. Autumn. Var. **supérba,** Hort. Lip white, with a purple blotch.

9. **cuneàta,** Lindl. Pseudobulbs ovate, clustered, 4 in. long, sheathed with lvs. at the base and 2-lvd. at the apex: lvs. dark green, strap-shaped, 1 ft. long: scape erect, 5–8-fld., as long as the lvs.; fls. 3–4 in. across; sepals and petals lanceolate, spreading, mostly chocolate-brown, greenish yellow at the tips, and few spots of the same color; labellum obovate-rotund, slightly wavy, creamy white, with 2 parallel ridges on the crest. Feb. Brazil. B.R. 31:8. I.H. 7:237. —A robust, free-flowering plant of the habit of *M. candida.*



2374. Miltonia flavescens. (×⅕)

10. **Warscewíczii,** Reichb. f. (*Odontoglóssum Wéltonii,* Hort. *Oncídium fuscàtum,* Reichb. f. *Oncídium Wéltonii,* Hort. *M. Wéltonii,* Hort.). Pseudobulbs 3–5 in. long, much flattened: lvs. linear-oblong, obtuse, 5–6 in. long: fls. 2 in. long from the tips of the lip to that of the upper sepal, numerous, borne in a branched nodding panicle; sepals and petals cuneate-obovate, waved and crisped, pale reddish brown, with whitish tips; labellum oblong, fan-shaped, bifid, white, with a large rose-purple disk on the center of which is a large, brownish yellow blotch. March. Peru. B.M. 5843. F. S. 18:1831. Var. **leucochìla,** Hort. Fls. pale purple; lower half of lip ruby-purple.

11. **Russelliàna,** Lindl. (*Oncídium Russelliànum,* Lindl.). Pseudobulbs ovate, ribbed, 2-lvd.: lvs. narrowly lanceolate: fl.-sts. dark purple, few-fld.: sepals and petals ovate-oblong, somewhat undulate, brownish purple with green margins; labellum oblong-cuneate, retuse, apiculate, violet, the crests or lamellæ on the disk margined with white. Dec. Brazil. B.R. 1830. P.M. 7:217.—Fls. rather small and dull in color.

12. **flavéscens,** Lindl. Fig. 2374. Pseudobulbs narrow: lvs. linear-ensiform: raceme many-fld., the stalk sheathed with bracts; fls. stellate, yellow, with the labellum somewhat spotted with purple; sepals and petals linear-lanceolate, acuminate; labellum pandurate, undulate-acuminate. June. Brazil. B.R. 1627 (as *Cyrtochilum flavescens*). Var. **grandiflòra,** Regel. Fls. larger, white at first, becoming whitish yellow; labellum obtuse. Gt. 39:1328.

M. Bértii=M. Bleuana × M. vexillaria.—*M. Bleuàna,* Hort. (Miltoniopsis Bleui, Bleu)=M. vexillaria × M. Roezlii. In habit like M. vexillaria: fls. 3–4 in. across; sepals and petals white, the latter purple-stained at base; lip nearly orbicular, notched at apex, white veined with pink in front of the yellow disk. Intermediate between the parents. A.F. 6:631; 9:1087. G. F. 5:198, 199. J.H. III. 68:277. O. 1913:104.—*M. Bleuàna grandiflòra,* a large-fld. form. G.M. 57:267.—*M. Bleuàna Peètersiæ,* Hort.=M. Bleuana Peetersii M. Roezlii × M. vexillaria Leopoldii) × M. Bleuana. Sepals and petals rose-purple below, the color on the sepals lighter; lip with the yellow crest crimson-bordered, with a rose band in front. G.C. III. 49:274.—*M. Bleuàna Stèvensii,* a dwarf variety with white fls. and lip crimson-striped.—*M. Blúntii Lubbersiàna,* Reichb. f. Fls. about 4 in. across; sepals and petals light yellow, blotched and barred with brown; lip purple at base, lined red-brown, the nearly orbicular front lobe lighter. Supposed to be a natural hybrid between M. spectabilis × M. Clowesii. G. 29:563. —*M. Chárlesworthii*=M. vexillaria "G. D. Owen" × M. Hyeana.—*M. festìva* =M. spectabilis × M. flavescens, probably.—*M. Hyeàna*=M. Bleuana × M. vexillaria var. Leopoldii.—*M. radiòla,* Hort. "Fls. larger, white, shaded purple, and heavily blotched with purple and yellow."—*M. Róbsonæ* =M. Roezlii × M. vexillaria "Queen Alexandra."—*M. Rógersonii,* Hort. "Like a large pale M. vexillaria."—*M. Sánderæ,* Hort. Fls. pale with a dark maroon eye. Hybrid between M. St. Andre × M. vexillaria "G. D. Owen." Gn. 77, p. 352.—*M. Schroederiàna,* Hort. Raceme 7–9-fld.; fls. 2½ in. long, fragrant; sepals and petals brown, yellow-marked; petals falcate, turned toward dorsal sepal; lip pandurate, rose-purple at base, the apex white. Cent. Amer. R. 2:96.—*M. travassosiàna,* Hort. Apparently a form of M. Regnellii with yellow sepals and petals.

HEINRICH HASSELBRING.
GEORGE V. NASH.†

MILTONIÒDA. *Orchidàceæ.* Bigeneric hybrids of Miltonia and Cochlioda. *M. Coòperi* is a garden hybrid between *Miltonia Warscewiczii* and *Cochlioda Noetzliana;* fls. brick-red with lighter tip to labellum, in slender branched spikes. *M. Hárwoodii* is a garden hybrid between *Miltonia vexillaria* and *Cochlioda Noetzliana.* Fl. about 2 in. long, the sepals and broader petals bright cerise-rose; lip miltonia-like, cream-white freckled with rose. *M. Líndenii* is a garden hybrid probably of *Cochlioda vulcanica* and *Miltonia Phalænopsis.*

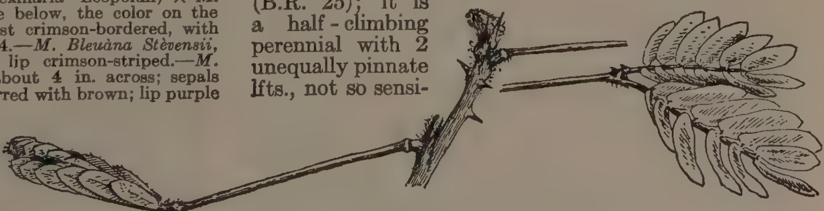
MILTONIÓPSIS. Garden hybrid, *M. Pauwelsiàna,* between *Miltonia Roezlii* and *M. vexillaria* var. *Leopoldii,* recorded as distinct from other kinds.

MIMÒSA (Greek, *a mimic,* alluding to the fact that the leaves of some species are sensitive). *Leguminòsæ.* Woody or herbaceous plants, mostly tropical, grown for the showy flowers or feathery foliage; of some species the leaves are sensitive. What the florists know as mimosas are acacias (chiefly *A. armata*).

Trees, shrubs or herbs of varying habit (sometimes woody climbers), mostly thorny or prickly, with bipinnate often sensitive lvs. (sometimes the lvs. reduced to phyllodia): fls. not papilionaceous, in close heads or head-like spikes, usually with 4 or 5 united petals, and a minute or obsolete calyx; stamens 4–10, exserted; pollen granular: pod flat, oblong or linear, breaking up into 1-seeded joints when ripe. Mimosa has stamens 10 or less (once or twice as many as the petals); Acacia has numerous stamens.—Of Mimosas there are probably 300 species, chiefly of Trop. Amer. A number of the bushy species, and the small trees, are planted more or less in warm countries for ornament. They require the treatment given the woody acacias.

A. *Plant herbaceous or practically so in cult.*

pùdica, Linn. SENSITIVE PLANT. HUMBLE PLANT. Fig. 2375. Cult. as an annual, but probably perennial in the tropics, and somewhat shrubby, erect, branching, hairy and spiny: lvs. long-petioled, with 2 or 4 subdigitate pinnate linear-oblong lfts.: fls. many, in globular-oblong heads on elongating axillary peduncles, purplish: pods comprising 3 or 4 spiny joints. Brazil, but widely naturalized in warm countries; run wild in the Gulf States. G.W. 2, p. 18.—Easily grown from seeds, which are sold by seedsmen. The plant grows readily in any place in which garden beans will thrive. It is grown for its sensitive foliage. The movements are usually quickest in young plants. When the lvs. are touched, the petiole falls and the lfts. close. The utility and the origin of these movements are not well understood. *M. sensitìva,* Linn., is a distinct plant (B.R. 25); it is a half-climbing perennial with 2 unequally pinnate lfts., not so sensi-



2375. Mimosa pudica.—Sensitive plant. Normal position of the leaf is shown on the right, and the collapsed position on the left. (×⅓)

tive as *M. pudica.* The word *pudica* is Latin for *modest* or *bashful.*

AA. *Plant distinctly woody: trees or bushes.*

B. *Primary pinnæ 1 pair.*

Spegazzínii, Pirotta. Bush, scandent and much branched, with recurved spines at base of petiole: lvs. sensitive, bipinnate; pinnæ 2, from 2–3 in. long; lfts. or pinnules very numerous, sessile and close together, oblong or linear-oblong and acute, 3-nerved: fls. rose-purple, in globular peduncled heads 1¼ in. diam., the heads axillary or in a terminal raceme; corolla 4-lobed; filaments rose-red and anthers yellow: pod 1 in. long, linear. Argentina. B.M. 7899. G.W. 2, p. 19. —A good greenhouse shrub; intro. in S. Calif. Var. **glaùca,** Hort., has glaucous foliage and whitish fls.

BB. *Primary pinnæ 2 pairs.*

guayaquilénsis, Steud. (*Acàcia guayaquilénsis,* Desf.). Pinnæ 4, with 3–5 pairs of ovate-obtuse glaucous lfts., of which the lower ones are smaller; opposite stipular spines at the base of the lf. Ecuador.

álbida, Humb. & Bonpl. Scandent, shrubby. branches cano-pubescent, spiny: pinnæ 2, each with 4 lfts., the inner ones of the lower pair very small, the others oblong and very unequal at base and acute at apex; petioles unarmed: fl.-heads twin, pinkish: pod about 1 in. long, grayish pubescent. Mex. to Peru. L.B.C. 3:249 (as *M. sensitiva*).—Intro. in S. Calif.

BBB. *Primary pinnæ 3–5 pairs.*

Ceratònia, Linn. (*Acàcia Ceratònia,* Willd.). Scandent glabrous shrub, with recurved prickles on branches and petioles: pinnæ about 5 pairs; lfts. obovate to roundish: pods glabrous, somewhat articulate and spiny, broadly oblong. W. Indies.

BBBB. *Primary pinnæ mostly 6–8 pairs or more.*

acanthocárpa, Poir. (*Acàcia acanthocárpa,* Willd. *A. brachyacántha,* Humb. & Bonpl.). Bush or small tree: pinnæ 12–14, with 6–15 pairs of oblong-pubescent lfts.: stipular spines 2: fls. in heads on twin axillary peduncles: pod falcate, spiny. Mex.

Dénhardtii, Hort. Ornamental shrub, the lvs. said to be almost as sensitive as those of *M. pudica:* branches glabrous or minutely hairy, striate, usually bent at each thorn: lvs. hairy, the pinnæ 12–14, the ultimate lfts. small (⅙in. long) and crowded and falcate-oblong-acute: fls. in club-shaped, axillary clusters: thorns 1–3 in. long. S. Amer.—Intro. in S. Calif.

rubicaùlis, Lam. Low tree, with many small hooked spines: pinnæ 8–20, the rachis prickly; lfts. 12–24, thin, ½in. or less long: heads reddish but becoming lighter colored, about ½in. long, on short simple peduncles; corolla very small: pod strap-shaped and somewhat falcate, 3–4 in. long. India, Afghanistan.—Intro. in S. Calif.

M. argéntea, Hort. Of climbing habit, suitable for warmhouse, said to be of the same section of the genus as M. pudica, slender, the sts. and branches hairy: pinnæ 2 or 3 pairs; lfts. about 40, oblong pinkish on the under side (as are the young shoots), green at the tips and silver-gray on lower half. Brazil.

L. H. B.

MÍMULUS (Latin, a *little mimic,* from the grinning fls.). *Scrophulariàceæ.* Mostly herbs (annual or perennial) with interesting irregular flowers in many colors, some of them border subjects and others flower-garden plants.

Low plants (sometimes shrubby), decumbent, ascending or erect, glabrous or pilose and often clammy: lvs. opposite, entire or toothed: fls. axillary, solitary or becoming racemose by the reduction of the upper lvs.; calyx 5-angled, with 5 short or long teeth; corolla-tube cylindrical, sometimes swollen at the throat; stamens 4, didynamous: caps. oblong or linear, loculicidally dehiscent.—Species probably 60 or 70, if Diplacus, Eunanus and Mimulastrum are included, mostly in extra-Trop. Amer., but some in Asia, Austral. and Afr. The genus is specially rich in W. N. Amer. This genus includes the monkey-flower, *M. luteus,* and the musk-plant, *M. moschatus.* Monkey-flowers are something like snapdragons, although they do not have a closed throat. They are 2-lipped fls., with 2 upper and 3 lower lobes, which are all rounded and usually irregularly splashed and dotted with brown on a yellow ground. Though perennial, they are commonly treated as annuals and are considerably used for pot cult. in winter, as well as for summer bloom outdoors. The musk-plant is grown for its scented foliage and pale yellow fls. It is sometimes used in hanging-baskets, but the foliage is so sticky that it gathers too much dust. The kinds described below are all perennial at least by underground parts (except *M. brevipes*), and most of them are natives of wet and shady places in N. W. Amer. They mostly grow 1–3 ft. high and bloom all summer. Diplacus is here included in Mimulus.

Mimulus plants (*M. luteus*) can be increased by sowing seed from January to April in pans of light sandy soil. They like a mixture of loam, leaf-mold and sand in equal parts. They may be kept in a temperature of 60° until they show signs of coming up, when they should be placed in a house that stands at about 50° during the night. As soon as the seedlings can be handled, they should be potted off into small pots and grown along in as cool a house as possible. The early-sown plants can be planted out in May in a cool shady situation, where, if they can have enough water to keep the roots moist, they will bloom fairly well. Those that are sown late can be grown on by shifting into 2-, 3-, 4- and 5-inch pots, using a compost of fibrous loam three parts, well-decayed cow-manure one part, and enough sand to keep the compost open. In the summer these may be grown outside in frames covered by lath shading. Late in autumn they may be brought into a coolhouse with 45° to 50° night temperature. Give them a place near the glass, and with care as to watering and ventilating they will bloom satisfactorily. They can also be increased from cuttings taken in the early spring.—*M. moschatus* can be grown from seed and cuttings. They may be planted out in a partly shaded situation, where they will grow all summer. In the autumn, lift some of the clumps and pot them. These may be grown in a coolhouse of about 45° at night. In the spring, when it is desired to increase the stock, take pieces of the new growth and place them around the side of a 3-inch pot, using the compost mentioned above; by keeping moist and shaded for a short time, they will soon root into the mixture and be ready to grow on. These may be shifted into 4-inch pots and soon will make fine little plants by their rapidly creeping growth. (J. J. M. Farrell.)

Youngeana, 5.

A. *Fls. violet, purple or lilac.*

1. **ríngens,** Linn. Herb with perennial rootstocks, branching, 1–3 ft. high, the sts. square: lvs. oblong or lanceolate, acute, serrate, clasping at base: fls. violet (varying to white), about 1 in. long, the throat very narrow; peduncle exceeding the calyx; calyx-teeth long and awl-shaped. Wet places, Nova Scotia to Man. and far S. B.M. 283.—A common and rather attractive native, useful for establishing and colonizing in wet places.

2. **alàtus,** Soland. St. somewhat winged or angled: lvs. ovate to oblong, acute, dentate-serrate, petioled:

fls. violet; peduncle shorter than calyx; calyx-teeth short and broad, abruptly sharp-pointed. Wet places, W. New England to Kans., south to Texas. L.B.C. 5:410.

AA. *Fls. yellow, brown or brick-red, often spotted.*

B. *Plant annual.*

3. **brévipes,** Benth. Viscid-pubescent, 1–2 ft.: lvs. bright green, to 4 in. long, lanceolate to linear: fls. large (to 1½ in. long) clear canary-yellow, the limb broad and with rounded lobes; calyx-teeth acuminate, very unequal. Calif.—Seeds are now offered.

BB. *Plant perennial, herbaceous.*

C. *Foliage not sticky or clammy.*

4. **cùpreus,** Regel (*M. lùteus* var. *cùpreus*, Hook. By Gray included in his var. *alpinus* of *M. luteus*). A Chilean species, differing from *M. luteus* in its tufted habit and the fls. yellow at first, finally becoming copper-colored, and the lobes possibly rounder and more nearly equal, the throat yellow, spotted brown. B.M. 5478. Gn. 24, p. 177. R.H. 1883, p. 284.—Perhaps not specifically distinct from the next.

5. **lùteus,** Linn. MONKEY-FLOWER. Fig. 2376. Glabrous, the larger forms 2–4 ft. high: lvs. parallel-veined, ovate to roundish to subcordate, sharply toothed, upper ones smaller, the lower sometimes laciniate: fls. deep yellow and commonly with dark spots within, the corolla 1–2 in. long; calyx ½in. or less long, somewhat ventricose. Alaska to Chile. B.M. 1501.—Monkey-flowers nearly always have yellow throats with brown dots. The lobes are sometimes clear yellow. In var. **rivulàris,** Lindl., only 1 lobe has a large brown patch. B.R. 1030. L.B.C. 16:1575. In var. **Youngeàna,** Hook., every lobe has such a patch. B.M. 3363. B.R. 1674 (as *M. Smithii*). In the common strains these patches are more or less broken up and the fls. mottled and dotted. F. 1863:73 (as *M. maculosus*). V. 10:289 (as *M. hybridus*). A very distinct set of colors is represented by var. **variegàtus,** Hook., the throat chiefly white, but with 2 yellow longitudinal lines dotted with brown on the middle lobe of the lower lip; all the lobes bright crimson-purple, with a violet reverse. B.R. 1796. B.M. 3336. L.B.C. 19:1872. G. 29:335. Modified as described under var. *Youngeana*. R.H. 1851:261. F. 1850:137. The pictures cited above bear various legends. The varietal names given above do not appear in the trade, the leading current names being *duplex* (hose-in-hose), *gloriosus*, *hybridus*, *hybridus tigrinus*, *hybridus tigrinus grandiflorus*, *quinquevulnerus maximus*, *pardinus*, *tigridioides* and *tigrinus*. Some of these names are advertised as varieties, but all of them frequently appear as if they were species. For *M. hybridus cupreus*, Hort., see *M. cupreus*, No. 4. *M. Búrnetii*, Hort., is a garden hybrid between *M. luteus* and *M. cupreus*. G.C. III. 30:107.

2376. Forms of Mimulus luteus. (×½)

Var. **alpìnus,** Gray (*M. Roèzlii*, Hort.). About 2–12 in. high, leafy to top: st. 1–4-fld.: corolla ¾–1¼ in. long.

CC. *Foliage sticky or viscous.*

6. **cardinàlis,** Douglas. Villous, 2–4 ft. high: lvs. sharply toothed: fls. red and yellow, the upper lobes much grown together and reflexed, the whole limb remarkably oblique. Water-courses, Ore. and Calif. to Ariz. B.M. 3560. R.H. 1857, p. 137 (as Diplacus). Mn. 8:161. F. 1843:193.—Hardy in Mass., with slight winter covering. Blooms first year from seed.

7. **Lèwisii,** Pursh. A more slender plant than No. 6, greener, and merely pubescent: lvs. minutely toothed: fls. rose-red or paler, the lobes all spreading. Shady, moist ground. Brit. Col. to Calif. and Utah. B.M. 3353 and B.R. 1591 (both as *M. roseus*).

8. **moschàtus,** Douglas. MUSK-PLANT. Perennial, by creeping sts. 1–3 ft. long, villous and sticky, with a musky odor: lvs. oblong-ovate: fls. pale yellow, lightly dotted and splashed with brown, the corolla about ⅔in. long. Brit. Col. to Calif. and Utah. B.R. 1118.—This and *M. luteus* have a broad throat. The fls. are normally about ¾in. across, but in F.M. 1877:248 (var. *Harrisonii*) they are 1½ in. across. Hardy, evergreen trailer for damp shady spots; good for planting under cool greenhouse benches.

BBB. *Plant perennial, woody or shrubby* (*at least at base*).

9. **glutinòsus,** Wendl. (*Diplacus glutinòsus*, Nutt.). Shrubby, 2–6 ft. high, nearly glabrous but sticky: lvs. narrow-oblong to linear, entire or denticulate, to 4 in. long, the margins at length revolute: fls. to 2 in. long, short-pedicelled, orange or salmon to pale buff, rather obscurely 2-lipped, the lobes toothed or notched. Rocky banks; common from San Francisco south. B.M. 354 (*M. aurantiacus*). G.W. 15, p. 649. A.G. 12:737. A.F. 12:1107.—A very variable species.

M. capénsis, Hort., is listed abroad as fit for cool greenhouse or pot-plant, or for warm border: 3–4 in. high: fls. bright orange, Apr.–July. Said to resemble M. cardinalis in habit and infl.—*M. radicans* of the lists is probably Mazus radicans (Mimulus radicans, Hook. f.).

WILHELM MILLER.
L. H. B.†

MÍMUSOPS

MÍMUSOPS (Greek, *ape-like*, but application not obvious). Including *Imbricària*. *Sapotàceæ*. Tropical trees, with milky juice, some of them producing edible fruit, planted far South mostly for ornament.

Leaves thick and shining, simple and entire, alternate, with inconspicuous transverse veins: fls. perfect, gamopetalous, the corolla of 6 or more lobes, but bearing twice as many appendages in the sinuses, the calyx of 6 or 8 sepals in 2 rows; stamens usually 6–8, inserted on the base of the corolla; staminodia present: fr. a globose or ovoid, 1–6-seeded berry, sometimes edible.—Probably 60 species in the tropics of both hemispheres. The species are confused and the names in the trade may not represent the species as now accepted by botanists. For a recent account of the W. Indian species, consult Pierre & Urban in Symbolæ Antillanæ, V (1904). The mimusops are fine evergreen trees, good for ornament in frostless countries, and yielding perfumery, oil, rubber and other products. The fls. are small, white, and usually borne in axillary fascicles. Some of the species become more than 100 ft.

high, and several of them yield hard and durable timber. A few species have been somewhat advertised in S. Calif. and S. Fla., but their cult. in this country is of small account. The sapodillo (which see) is a closely allied tree.

Kaùki, Linn. (*M. dissécta,* Hook. *M. Hoòkeri,* A. DC. *M. Bòjeri,* A. DC. *Kaukénia Kaùki,* Kuntze). Tree, 20–35 ft., the young branches gummy, lightly pubescent: lvs. crowded at ends of branches, obovate-elliptic, or ovate, 4 in. long, long-petioled, obscurely nerved, silky-white beneath: fls. clustered on tomentose twin or solitary pedicels not exceeding the petiole; corolla ⅓in. long, with 18 narrow acute lobes or petals, the exterior narrower; calyx-lobes 6; staminodes 6–8, lobed or serrate; stamens 6–8; ovary 6–7-celled: berry about 4-seeded, to 1 in. diam., obovoid and smooth. Birma to Malaya. B.M. 3157. Cultivated in West Indies.

Balàta, Miq. (*Áchras Balàta,* Aubl. *M. bidentàta,* A. DC. *M. Pierreàna,* Baill.). Tall tree, to 100 ft.: lvs. petioled, oblong-lanceolate, elliptic or oblong-obovate, acuminate or obtuse, about 4 in. long, grayish velutinous or nearly glabrous beneath, lightly very many-nerved: pedicels 10 or more, somewhat shorter than the petioles: calyx-lobes or sepals 6, grayish velutinous on the back; corolla-lobes 6 or 8 and more, the exterior ones 2-lobed or -parted and denticulate; stamens 6 or 8; staminodes lobed or denticulate; ovary 8-10-celled: berry ovoid, about 1 in. long. W. Indies and S.—It is a variable species, with a number of named botanical varieties in the W. Indies. The *M. globosa* of lists probably belongs here.

2377. Four-O'clock.—Mirabilis Jalapa.

Cómmersonii, Engler (*M. coriàcea,* Miq. *Imbricària coriàcea,* A. DC.). Tree: lvs. oval-obovate, retuse, short-petioled, entire, shining above and slightly pilose beneath, coriaceous: pedicels solitary, or twin, axillary, much shorter than lvs.: outer calyx-lobes reddish pubescent outside but nearly glabrous inside, the inner ones narrower and white-velvety. Madagascar.—Said to be intro. in S. Calif.

parvifòlia, Radlk. (*M. Sièberi,* Chapm., Gray, et al. *M. floridàna,* Engler. *M. bahaménsis,* Pierre. The *M. Sièberi,* A. DC., is a form of *M. Balata.*). Wild Dilly. Becoming 35 ft. tall: lvs. elliptic to obovate, retuse, green, 2–4 in. long, slightly revolute, slender-petioled: corolla-segms. 6, oblong and exceeding the narrow appendages; fertile stamens 6; staminodia short-triangular, nearly entire: fr. nearly 1 in. diam., brownish or yellowish, maturing in autumn, said to be edible. Fla. Keys to Trinidad.

Eléngi, Linn. Tall tree (becoming 50 ft.): lvs. elliptic and short-acuminate (3–3½ in. long), rhomboid at the base, petiole ¾in. long: corolla-lobes about 6, narrow-lanceolate; fertile stamens 8; staminodia pilose, acute, entire or nearly so: fr. 1 in. or less, ovoid, 1- or 2-seeded, yellow, edible. E. Indies.

díspar, N. E. Br. Smaller tree than *M. Elengi:* lvs. small, cuneate-oblanceolate, obtuse, rusty-tomentose when young, but become glabrous-green, the petiole ⅓in. or less long, and the blade ¾–2 in. long: fls. 12–16, in umbels on the tips of the branches; sepals 6–8, in two series; petals 18–24, in three series, linear-lanceolate, yellow; stamens 6–8; staminodia lanceolate-acuminate channelled: fr. size of an olive, yellow. Natal.—Intro in S. Calif. L. H. B.

MÌNA: *Quamoclit.*

MINKELÉRSIA (Dr. Minkelers, professor of physics in the University of Louvain). *Leguminòsæ.* Creeping or twining herbs of very few species, in Mex. Hooker writes that "the genus is considered by Bentham to be little more than a section of Phaseolus, distinguished by its longer calyx-lobes, and the elongate petals." None of the species seems to be regularly in cult. The following has been recently described. *M. biflòra,* Hemsl., has a tuberous root and long very slender twining sparsely hairy st.: lfts. 3, nearly equal, orbicular-ovate, obtuse: fls 1½ in. long, pale red-purple, 2 on each axillary peduncle: pod linear and straight, containing very small seeds. Mex. B.M. 7819.

MINT: *Mentha.*

MINT GERANIUM: *Chrysanthemum Balsamita.*

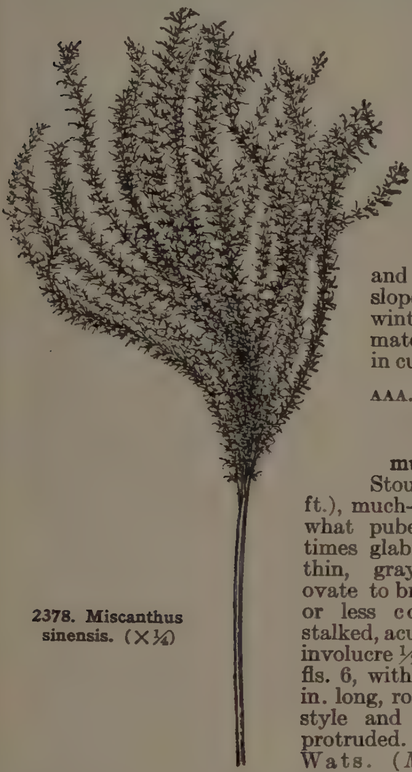
MIRÁBILIS (The old name was *Admirabilis,* meaning wonderful, strange; shortened by Linnæus to Mirabilis). *Nyctaginàceæ.* Interesting flower-garden herbs.

The fls. have no corolla, but the calyx is colored and tubular and exactly like a corolla in appearance. The fls. are surrounded by a leafy involucre, and sometimes (as in *M. Jalapa*) only 1 fl. is borne in an involucre, simulating a corolla in a 5-cleft calyx; stamens 5 or 6, as long as the perianth, their filaments united at the base; style 1, with a capitate stigma: fr. hardened, caps.-like and indehiscent.—About a dozen species in the warmer parts of Amer.; or twice that number if Oxybaphus is included. The species of Mirabilis are perennial herbs, although grown as annuals from seeds, with lvs. petioled and opposite, and fls. solitary or paniculate and nearly or quite sessile in the involucres.

A. *Involucre containing only 1 fl.: plant glabrous or very nearly so.*

Jalàpa, Linn. Four-O'clock. Marvel of Peru. Fig. 2377. Erect-bushy quick-growing herb, germinating readily from the large conical-oblong frs., 2–3 ft. high, bearing profusely in late summer and fall long-tubed funnelform fls. in white and shades of red and yellow, and striped, opening in cloudy weather or late in the afternoon (whence the common name four-o'clock), and closing in the morning: lvs. ovate-lanceolate, short-petioled, acuminate, entire: fls. in clusters amongst the lvs.; stamens not exserted. Trop. Amer. B.M. 371. G. 2:499.—Cult. from early times, and always a favorite. In the tropics it has tuberous roots, and these were once supposed to be the source of jalap, whence the name *Jalapa.* There are dwarf and compact varieties; also forms with variegated foliage. The four o'clock is an "old-fashioned" fl. It is treated as a tender annual, thriving in any garden soil. It is a useful plant for growing in a hedge (plants 1 ft. apart) at the rear of the fl.-garden. Sometimes it comes up in the spring from self-sown seeds. Even as far north as New York, it often produces tuberous roots large enough to be lifted and stored like dahlias.

AA. *Involucre containing 1–3 fls.: plant viscid-pubescent.*



2378. Miscanthus sinensis. (×¼)

califórnica, Gray. Plant 1–3 ft. tall, the many sts. ascending from a somewhat woody base: lvs. thick or almost fleshy, ovate-oblong to round-ovate, short-stalked: involucres 5-cleft, short-peduncled, containing 1–3 rose-purple fls. ½in. long, with stamens sometimes protruded. S. Calif. to Utah and S., on sunny slopes, blooming all winter in milder climates.—Little known in cult.

AAA. *Involucre containing 3 or more long-tubed fls.*

multiflòra, Gray. Stout and tall (2–3 ft.), much-branched, somewhat pubescent or sometimes glabrous: lvs. rather thin, gray-green, lance-ovate to broad-ovate, more or less cordate, short-stalked, acute or acuminate: involucre ½in. long, stalked; fls. 6, with a tube often 2 in. long, rose to purple, the style and the 5 stamens protruded. Var. **pubéscens,** Wats. (*M. Froèbelii,* Greene), is very pubescent throughout. The *M. multiflora* of B.M. 6266 is probably this variety. The species ranges from Colo. and Texas to S. Calif. and south. Little known in cult.

longiflòra, Linn. Plant 2–3 ft., glandular-pubescent above: lvs. cordate and usually acuminate, short-stalked, pubescent: fls. pubescent, with a very narrow tube 5–6 in. long, and a small, flaring white, rose or violet limb, very fragrant at evening. Mex.—An old garden plant, but less frequent than *M. Jalapa;* easily grown from seeds. It has been hybridized with *M. Jalapa.*

L. H. B.

MIRASÒLIA: *Tithonia.*

MISCÁNTHUS (Greek, *miskos,* a stem, and *anthos,* a flower). *Gramíneæ.* EULALIA. Tall perennial grasses with ample terminal feathery fan-shaped panicles, allied to the sugar-cane and Erianthus; often planted for bold lawn specimens and in borders.

Spikelets 1-fld., in pairs at the joints of the rachis, one nearly sessile, the other pedicellate, usually awned; clusters of silky hairs arising from the bases of the spikelets give the panicle its beautiful feathery appearance.—Comprises about 6 species in S. and E. Asia, several of which are cult. for ornament. Includes the eulalias of the trade but not Eulalia, Kunth, which is referred to Pollinia, by Hackel.

Although many progressive nurserymen now advertise these favorite grasses as Miscanthus, the name eulalia will probably remain in the English language as a thoroughly naturalized word, like geranium and chrysanthemum. Eulalias probably rank among the first half-dozen most popular grasses cultivated for ornament. They are remarkably hardy and are universal favorites for bedding. One of the commonest and best designs for a bed of ornamental grasses employs *Arundo Donax* as a tall centerpiece, surrounded by eulalias. Propagated by seed or division of roots.

sacchárifer, Benth. (sometimes written *sacchariflòrus. Imperàta sacchriflòra,* Maxim.). Distinguished by its nearly or quite awnless spikelets. China. Gt. 1862:357.—Procurable of dealers in Japanese plants.

nepalénsis, Hack. HIMALAYA FAIRY-GRASS. Spikelets one-fourth as long as the brown involucral hairs: lvs. smooth on the margin. Himalayas.—Occasionally cult.

sinénsis, Anders. (*Eulàlia japónica,* Trin.). Figs. 2378, 2379. Spikelets about equaling the white or subviolet involucral hairs: culm 4–9 ft.: lvs. 2–3 ft., margins scabrous: panicle 6–12 in., formed late in the season.—Established plants form clumps as much as 18 ft. in circum. Sometimes found escaped from cult. The forms in cult. are mostly the following varieties: Var. **variegàtus,** with lvs. striped; var. **zebrìnus,** lvs. banded. These two varieties are not quite so hardy as the type, and are usually prop. by division, as the seeds are not so sure to come true. Gn. 61, p. 74. Gng. 4: 375; 6:107. B.M. 7304. G.W. 3:423. Var. **gracíllimus** (*Eulàlia gracíllima univittàta, E. japónica gracíllima,* etc.). Lvs. much narrower than the type. Gn. 50, p. 108. Gng. 5:273. R.B. 21, p. 179.

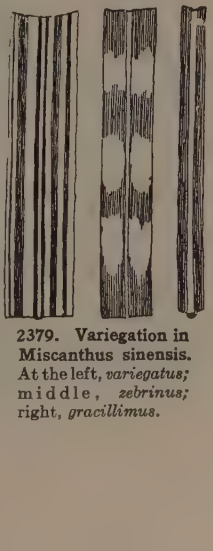
A. S. HITCHCOCK.

MISCHOPHLŒUS (*stem* and *bark,* of no evident application). *Palmàceæ.* One unarmed palm of medium height with pinnatisect lvs., from the island of Ternate in the Malay Archipelago, listed abroad. It is allied to Areca, from which it differs in having more stamens (9), in having the inferior fls. on the spadix branches in 3's rather than in 2's or solitary, and in other technical characters. The species is **M. paniculàta,** Scheff. Lvs. terminal, unequally pinnatisect, the segms. lanceolate and double-toothed and mostly many-nerved: fls. small, in double-branched spadices: fr. ovoid, with terminal stigma, the pericarp fleshy or fibrous.

MISTLETOE of the Old World is *Viscum album;* of America, *Phoradendron flavescens.* See, also, *Loranthus.*

MITCHÉLLA (Dr. John Mitchell, of Virginia, one of the first American botanists, correspondent of Linnæus). *Rubiàceæ.* PARTRIDGE-BERRY. TWIN-BERRY. SQUAW-BERRY. A very attractive native trailer.

There are two species of Mitchella, one of which (*M. undulata,* Sieb. & Zucc.) grows in Japan. The native partridge-berry has small shining evergreen roundish lvs., sometimes marked with white lines, and bright scarlet berries, often borne in pairs, which remain all winter. This plant can be easily collected, and is also procurable from dealers in hardy plants. It thrives under evergreen trees, forming mats. Little pans with fruiting plants are often sold by florists in midwinter, particularly about Christmas time. The fls., which are borne in spring, are small, white, with pinkish throats, and are fragrant. The berries are edible, but nearly tasteless. Fls. twin, the ovaries united into one; calyx 4-toothed; corolla funnel-shaped, 4-lobed; lobes spreading, densely bearded inside, valvate in the bud: fr. a 2-eyed berry or double berry, red (rarely white), persisting through the winter.



2379. Variegation in Miscanthus sinensis. At the left, *variegatus;* middle, *zebrinus;* right, *gracillimus.*

rèpens, Linn. Partridge-Berry. Squaw-Berry. Fig. 2380. Lvs. opposite, round-ovate, petioled, with minute stipules, often whitish veined: fls. in pairs, on the apex of a peduncle. Nova Scotia to Minn., south to Fla. and Mex. Mn. 3:49. L.B.C. 10:979. Gn.M. 2:19.—Attractive in half-shaded spots in the wild garden and rockeries. Prop. by division. L. H. B.†

2380. Mitchella repens.—Partridge-berry. (×½)

MITÉLLA (diminutive of *mitra*, a cap; applied to the form of the young pod). *Saxifragàceæ*. Mitrewort. Bishop's-Cap. Low slender perennials, with somewhat creeping rootstocks and racemes of small and greenish or white flowers, sometimes planted in shady places.

Closely related to Tiarella, but the petals of the latter are entire, while in Mitella they are pinnatifid: lvs. round, heart-shaped, mostly alternate, on rootstock or runners, with slender petioles; those on flowering sts. opposite, if any; calyx short, 5-lobed, the lobes valvate in the bud, spreading; petals 5, inserted on throat of calyx, very slender; stamens 10 or 5, very short: fr. soon widely dehiscent. A few natives of N. Amer., 2 species in E. Asia.—Offered by some dealers in native plants.

A. *Scapes usually leafless.*

B. *Fls. numerous.*

trífida, Graham (*Ozomèlis trífida*, Rydb.). Lvs. round-reniform or cordate, crenately toothed and sometimes incised or lobed, 1–3 in. across: scape 9–12 in. long; fls. somewhat scattered on one side of spike; petals 3–5-parted, small; stamens 5, opposite the calyx-lobes. Canadian Rockies.

BB. *Fls. few (about 5).*

nùda, Linn. Lvs. rounded or kidney-shaped, deeply and doubly crenate: raceme 4–6 in. long. Does well in moist shady situations. May–July. Labrador to Brit. Col. and south to Pa., in bogs and cold woods. A.G. 13:518.

AA. *Scapes bearing lvs.*

B. *Lvs. on scape alternate.*

cauléscens, Nutt. (*Mitellástra cauléscens*, Howell). Raceme loose; stamens alternate with the pinnatifid petals. Mont. to Brit. Col. and N. Calif.

BB. *Lvs. on scape opposite.*

diphýlla, Linn. Lvs. acutely heart-shaped, somewhat 3–5-lobed, toothed: raceme 6–8 in. long. May. Que. to N. C. and Mo. V. 12:189.—A good plant for the rockery. M. B. Coulston. L. H. B.†

MITRÀRIA (from the mitre-shaped pods). *Gesneriàceæ*. One Chilean scandent shrub, prized for its bright scarlet flowers.

Leaves opposite, usually small, few-toothed: fls. stalked, solitary in the axils; calyx relatively small, free, 4–5-parted, with 2-lobed large bracts; corolla-tube much exceeding the calyx, ventricose and contracted near the top, the 5 lobes nearly equal; stamens 4, attached near the bottom of the corolla. *M. coccínea* Cav., is the only species: lvs. ovate and acute: fls. about 1½ in. long, pendent on peduncles much exceeding the lvs. Chile. B.M. 4462. F.S. 4:385. J.H. III. 48:471. G. 5:464; 36:817.—It is a dense-growing subscandent evergreen greenhouse plant (standing out-of-doors in parts of England), of easy cult., blooming in summer and autumn.

MITREWORT: *Mitella*. False M., *Tiarella*.

MITRIOSTÍGMA (Greek, *mitre-shaped stigma*, from the conspicuous stigma, which is club-shaped, the 2-cut summit suggesting a cap). *Rubiàceæ*. This genus includes the charming evergreen tender shrub known to the trade as *Gardenia citriodora*. It makes a low or medium-sized bush of compact and branching habit and bears a great profusion of fls. that resemble those of the orange in odor, size, color and general appearance. The fls. are white, salver-shaped, 5-lobed, tipped with pink in the bud, and borne in dense axillary clusters. This plant is a favorite in the S., together with the Cape jessamine, but is little known in northern conservatories. The genus contains 2 species in Afr., very like Gardenia and distinguished by technical characters as the 2-celled rather than 1-celled ovary.

axillàre, Hochst. (*Gardènia citriodòra*, Hook.). Lvs. opposite, petiolate, elliptic-lanceolate, subacuminate, glabrous; stipules awl-shaped from a broad base: calyx not ribbed, lobes lanceolate, acuminate, equal; corolla salver-shaped, the tube twice as long as the calyx, lobes obovate, obtuse: fr. oval. S. Afr. B.M. 4987. R.H. 1859, p. 175; 1886:348. F.S. 12:1254. J.H. III. 48:449. Gn.W. 4:53. Wilhelm Miller.

MOCCASIN FLOWER: North American name for species of *Cypripedium*.

MOCK ORANGE: *Philadelphus*.

MODÉCCA (an E. Indian name). *Passifloràceæ*. Thirty or more species of erect or twining and tendril-climbing plants in the tropics of Afr., Asia, Austral., little known in cult. Herbs or undershrubs: lvs. alternate, entire or palmately 3–5-lobed, gland-bearing at base of blade: fl.-stalks axillary, terminating in a tendril, bearing greenish or whitish unisexual fls., the hypanthium or calyx-tube not elongated; male fls. with 5 very narrow laciniate petals included within the fl.-tube, 4–5 stamens and 5 staminodes or disk-glands; female fls. with 10 staminodes or disk-glands in 2 series, and a stipitate 1-celled ovary; both kinds of fls. with a corona of interesting structure: fr. a coriaceous or fleshy 3-valved or indehiscent caps. *M senénsis*, Mast. (*Clemánthus senénsis*, Klotzsch. *Adènia senénsis*, Engler), is a tall-climbing shrub from Senna, Zambesi and other places in Trop. Afr.: glabrous and rather glaucous: lvs. 5-parted, pale green, glaucous beneath, the segms. narrow and obtuse. calyx corolla-like, pale yellow, narrow campanulate, about 1 in. long; petals very small and contained within the calyx. B.M. 7763. L. H. B.

MOEHRÍNGIA: *Arenaria*.

MÒHRIA (from Daniel Mohr, a German botanist; died 1808). *Schizæàceæ*. A genus of S. African ferns, having the habit of Cheilanthes, but the sporangia of

the Schizæaceæ. *M. caffròrum*, Desv. Lvs. in tufts, 9–22 in. long, 2–4 in. broad, tripinnatifid, the pinnæ close, the pinnulæ oblong, deeply cut or pinnatifid. The lvs. have a pleasant odor when bruised. Interesting as a rarity but not of commercial value. *M. achilleæfòlia*, Hort., is nearly quadripinnatifid, and is said to have a different odor.
R. C. Benedict.

MOLÌNIA (J. Molina, a writer upon Chilean plants). *Gramineæ.* A cespitose perennial allied to Eragrostis. Panicle contracted; spikelets sub-cylindrical, 2–4-fld., purplish; glumes short, somewhat unequal; lemma 3-nerved, rounded on back, pointed but awnless.—Species 1, native of Cent. Eu. and Temp. Asia, sparingly intro. in the U. S.

cærùlea, Moench (*Aìra cærùlea,* Linn.). Culms tufted, 1–3 ft. high: lvs. rather rigid, slender pointed. The usual form in cult. is var. **variegàta,** with striped lvs., used for bedding. Dept. Agric., Div. Agrost. 20:133.
A. S. Hitchcock.

MOLOPOSPÉRMUM (*striped seed,* a Greek compound). *Umbellíferæ.* One species, **M. cicutàrium,** DC. (*Ligùsticum peloponnesìacum,* Linn.), a large perennial of the mountains of S. Eu., grown sometimes for its handsome dense foliage; prop. by division or by seeds: 3–5 ft. with large hollow sts.: lvs. ternately decompound, the lfts. lanceolate, with pinnatifid segms.: fls. small, in umbels, the terminal umbels larger, yellowish white, the flowering sts. standing well above the clump of foliage. G.W. 12, p. 411.—Hardy in England; thrives in good garden soils.

MÓLTKIA (Count Joachim Gadske Moltke, Denmark, died 1818). *Boraginàceæ.* About a half-dozen perennial cano-pubescent mostly cespitose herbs allied to Lithospermum, but having stamens exserted and different nutlets; S. Eu. and Asia. Fls. blue or yellow, racemose or in terminal cymes; corolla-tube more or less funnel-shaped, the broad throat naked or hairy, the 5 lobes obtuse, erect or nearly so (spreading in Lithospermum); stamens 5. Two or 3 of the species are used more or less in rock-gardens and as alpines.

petræ̀a, Boiss. (*Lithospérmum petræ̀um,* A. DC. *Échium peræ̀tum,* Tratt.), from southeastern Eu., is a good rock-plant, 6–8 in., more or less woody, hoary: lvs. to 1½ in. long, narrow-linear to linear-oblong, the margins recurved: fls. deep violet-blue, in simple forked or branching revolute cymes; corolla-tube twice as long as calyx; lobes erect, short and rounded; style slender, exserted. B.M. 5942. B.R. 29:26.

cærùlea, Lehm. Suffruticose, the sts. erect, rigid and thickish, with crowded lvs., canescent: lvs. oblong-spatulate and obtuse, those on the st. linear-lanceolate and somewhat acute: fls. blue, in scorpioid racemes, the corolla-tube slender and exceeding the calyx; filaments exserted; calyx-lobes linear-lanceolate. Asia Minor.

graminifòlia, Benth. & Hook. (*L. graminifòlium,* Viv.). By some kept in Lithospermum: st. somewhat woody below, but ascending, appressed-hairy: lvs. linear, revolute: fls. purple-blue, about ½in. long, the corolla glabrous and with erect lobes; stamens somewhat exserted. Italy. G.C. III. 47:213. Gn. 65, p. 147. Gn.W. 21:668.—A dwarf shrub with grayish lvs., said to prefer a dry and sunny place on limestone.
L. H. B.

MOLUCCÉLLA (diminutive, made from Molucca). Also written *Mollucella. Labiàtæ.* Half-hardy annuals, flowering in midsummer, interesting because of the cup-shaped calyx.

Annual: corolla-tube included, with an oblique hairy ring within, the upper lip erect, the lower trilobed, the middle lobe broader, notched; stamens ascending under the hood, the anthers attached by lateral pedicels to the tip of the filament, cells divergent; style bifid: nutlets 4, convex on one side, angular on the other, broader upward, truncate.—Of 25 described names only 2 now remain in this genus as accepted species. Bentham & Hooker place this genus near Lamium. Other genera of garden value in which the upper lip of the corolla is concave or vaulted and often villous within are Stachys, Leonurus and Phlomis. From these Moluccella is easily distinguished by its calyx. The fls. are white, tipped pink, scarcely if at all thrust out of the calyx, and borne in whorls of 6–10.

To this genus belongs the shell-flower, a quaint old annual plant, that self-sows in old-fashioned gardens, but is now rarely advertised for sale. Start the seed in frames in February and March; the seedlings may be transplanted to the rockery or border in May. They seem to like a sandy loam.

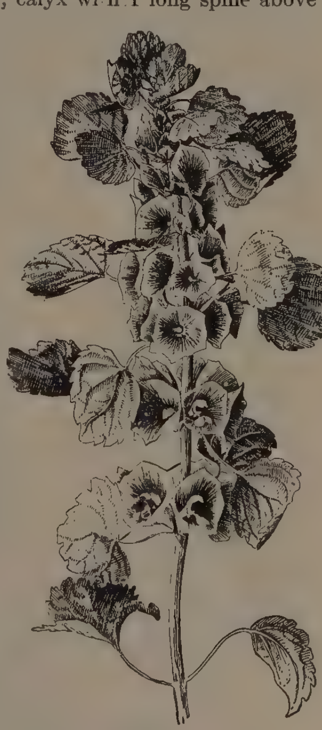
A. *Calyx not prickly.*

læ̀vis, Linn. Shell-Flower (so called because of the shell-like calyx in which the seeds nestle like eggs). Molucca Balm. Fig. 2381. Height 2–3 ft.: st. simple or branching below, fl.-bearing almost from the base: lvs. long-petioled, rounded-subcordate, teeth coarse, round: fls. in whorls, 6-fld.; bracts shorter than calyx-tube; corolla white, shorter than calyx; calyx bears 5 small thorns. W. Asia. B.M. 1852.—Fls. odorous.

AA. *Calyx beset with long prickles.*

spinòsa, Linn. Height 6–8 ft.: lvs. ovate, deeply and sharply cut: fls. in whorls, 6–10-fld.; bracts subulate, spiny, shorter than calyx-tube; corolla white, limb longer than calyx-tube; calyx with 1 long spine above and 7 others below. S. Eu., Syria. B.R. 1244 (as *Chasmonia incisa*).—Annual or biennial, with brownish red square sts., bristling calyx and gaping corolla. Said to have been cult. in England since 1596.

Wilhelm Miller.
A. C. Hottes.†



2381. Moluccella lævis. (×⅓)

MOMÓRDICA (*momordi,* from *mordeo,* to bite, since the seeds appear to have been bitten). *Cucurbitàceæ.* Annual or perennial tendril-climbing herbs of tropical countries, some of which are cultivated for ornament and also for the edible fruits.

Annual or perennial: fls. monœcious or diœcious, the staminate solitary or panicled, the pistillate solitary; corolla and calyx similar in sterile and fertile fls.; corolla-segms. 5, often extending nearly to the base, making a rotate or broadly campanulate fl.; stamens usually 3, the short filaments free, one of the anthers 1-loculed and the others 2-loculed; style single and long, with 3 stigmas: fr. oblong or nearly spherical, small, often rough, usually many-seeded, sometimes splitting into 3 valves, but usually indehiscent; seeds usually flattened, often oddly marked or sculptured: tendrils simple, in this distinguished from Luffa.—Species about 35, chiefly in Trop. Afr. also Trop. Asia. Two momordicas (*M. Charantia* and *M. Balsamina*) are known to American gardens as ornamental vines, but the frs. of *M. Charantia* are eaten by the American Chinese. They are tender annuals and thrive where cucumbers and gourds will grow. They are excellent in the S. for covering porches and arbors. *M. Elaterium* of the catalogues is Ecballium, which see.

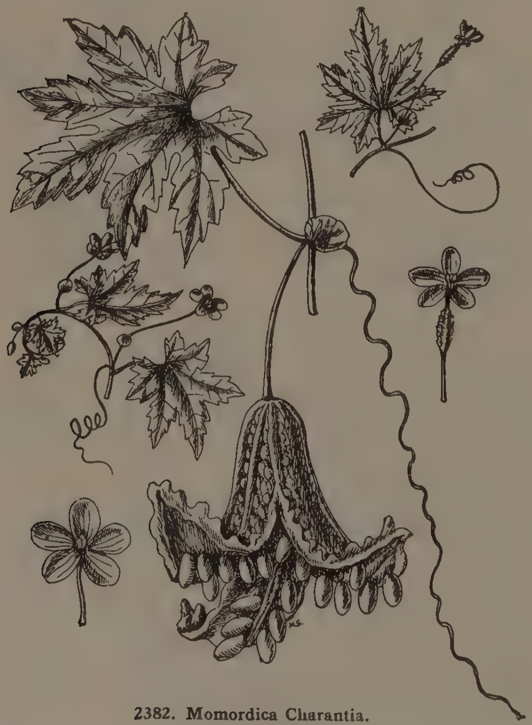
A. *Bract usually about midway (or at base) on the peduncle, entire: all peduncles bracted.*

Charántia, Linn. Balsam Pear. Fig. 2382. Running 10 ft. or more, the st. slightly pubescent and furrowed: lvs. roundish, dull green, pubescent beneath (at least on the ribs), 5–7 lobes with rounded sinuses, the lobes sharp-toothed and notched: fls. yellow, 1 in. across, both the sterile and fertile solitary: fr. yellowish, oblong, pointed, furrowed lengthwise and tuberculate, 6 or 7 in. long, at maturity splitting into 3 divisions and disclosing the bright scarlet arils of the white or brown carved seeds. Trop. Asia and Afr., and naturalized in W. Indies. B.M. 2455. G.C. III. 52:473. A.G. 13:525.—The Chinese gardeners about the American cities grow this plant under the name of la-kwa, for the edible pulpy arils surrounding the seeds, and also for the edible fr. itself (which is prepared, usually by boiling, before it is ripe). The rind is sometimes dried and used in medicinal preparations (see Bailey, Bull. No. 67, Cornell Exp. Sta., with illustrations). The odd seeds cause it to be called the "art pumpkin" by some persons.

Var **abbreviàta,** Ser. (*M. zeylánica,* Mill.). Plant smaller: lobes of lvs. narrower: fr. shorter, ovate-mucronate, with rows of sharp spines; seeds small, commonly smooth. In the tropics.—Perhaps specifically distinct; but *M. Charantia* runs into many forms.

AA. *Bract of sterile peduncle near the top, toothed: peduncle of fertile fl. bracted at base or not at all.*

Balsámina, Linn. Balsam Apple. Slenderer and more graceful, bright green throughout, glabrous, the foliage smaller and neater: lvs. cordate-orbicular in outline, 3 in. or less across, 3–5-lobed, with rounded sinuses, the lobes and the few notches or teeth acute: fls. solitary, nearly or quite 1 in. across, yellow, often with blackish center: fr. orange, 2–3 in. long, ovoid and more or less narrowed each way, smooth or tuberculate; seeds compressed, nearly smooth. Widely distributed in Afr. and Asia, and naturalized in the W. Indies. G.C. 1848:271. R.H. 1857, p. 182. G.M. 48:3.—A neat vine, growing 4–6 ft.



2382. Momordica Charantia. (Main spray × ¼)

AAA. *Bract near the top of the sterile peduncle, entire.*

involucràta, E. Meyer. Much like *M. Balsamina,* but teeth of lvs. blunt, with a short mucro, fls. larger, bract much larger: fls. white or cream-white, often dotted with black: fr. sulfur-yellow, changing to scarlet, bursting, 2 in. long. S. Afr. R.H. 1865:350 (as *M. Balsamina* var. *leucantha*). B.M. 6932.—A very slender and graceful climber, with the peduncle bract against the calyx, like an involucre. Intro. to American trade about 1890.

M. cochinchinénsis, Spreng. (M. mixta, Roxbg.), is a large species with 3-lobed lvs., pale yellow, purple-eyed fls., 4 in. across, and an oblong, bright red fr. 4–7 in. long. Farther India. B.M. 5145. F.S. 14:1478. G.C. III. 16:531. G.M. 37:777.

L. H. B.

MONÁNTHES (named for the often solitary flower). *Crassulàceæ.* About 10 little fleshy herbs of the Canary Isls. and Morocco. Perennial, tufted, mostly glandular-hairy: lvs. fleshy, clavate or cylindrical, opposite or alternate, part or all of them rosulate: fls. reddish or orange, on slender peduncles, solitary or in cymes or racemes; sepals connate at base; petals 6–12, small, lanceolate; scales broad and petal-like. Closely allied to Cotyledon and Sempervivum, and presumably requiring similar treatment. From Sempervivum it differs in the much more developed scales in the fl., opposite the carpels. Fanciers are likely to grow a number of species; the following description will indicate what the plants are like.

atlántica, Ball. Branches prostrate, 1–3 in. long, cylindric, bearing toward the end a dense imbricated rosette of 20 or more lvs., the latter about ⅙in. long: fls. golden yellow, speckled red on back, on peduncles from the ends of the branches; petals 6, elliptic-ovate, acuminate. Canaries, Morocco. B.M. 5988 (as *M. muralis*).

L. H. B.

MONÁRDA (after Nicolas Monardes, a Spanish physician and botanist, who published in 1571 a book containing accounts of American products. See Fig. 1850). *Labiàtæ.* Horse-Mint. Annual and perennial, erect, aromatic herbs.

Leaves dentate or serrate: calyx tubular, narrow, 15-nerved, nearly 5-toothed, mostly villous in the throat; fls. rather large, white, red, purplish, yellowish or mottled, in dense capitate clusters, mostly bracteate, terminal and sometimes axillary, the bracts often highly colored; corolla glabrous within, tube slightly dilated above; upper lip erect or arched; lower lip spreading, 3-lobed, the middle lobe larger or longer than the others; anther-bearing stamens 2, usually exserted, the posterior pair rudimentary or wanting; anthers linear; ovary 4-parted.—About 12 species, natives of N. Amer., including Mex.

This includes the Oswego tea (*M. didyma*), one of the most brilliant of our native wild flowers, being surpassed in the intensity of its red only by the cardinal-flower. It is a rather coarse herb, with large heads of gaping, wide-mouthed flowers, which have none of the refinement of the cardinal-flower. For mass effects, however, these plants are very striking. They grow wild along the banks of streams, lighting up the dark corners of the woods. This suggests their proper place in landscape gardening. They should be grown in masses, in wild spots against a dark background. However, they can, if desired, be grown in an ordinary sunny border without more moisture than usual. As a bedding plant they would be inferior to *Salvia coccinea*, the flowers being shorter-lived. The white- and rose-colored varieties are less desirable. *M. fistulosa* is the same type of plant, and is procurable in colors ranging from white, flesh-color and lilac, through rose and crimson to deep purple, but not scarlet. This species is very variable in height. The lighter-colored varieties are usually less robust.

Monardas are easy of culture, thriving in any good soil. They spread quickly, and therefore need frequent separation, which operation is best done in the spring, as plants disturbed in autumn will often winter-kill.

2383. Monarda didyma. (×⅓)

A. *Calyx slightly hairy at the throat.*

dídyma, Linn. (*M. Kalmiàna*, Pursh. *M. coccínea*, Hort.). Oswego Tea. Bee-Balm. Fragrant Balm. Fig. 2383. St. acutely 4-angled: lvs. thin, ovate-lanceolate, acuminate. B.M. 145 (erroneously as *M. fistulosa* var.), and 546. R.B. 26:49. G.W. 14, p. 618. Vars. **álba** and **ròsea,** Hort., are offered, but the latter should be compared with the next species. In 1893 John Saul advertised *M. Kalmiana* as if horticulturally distinct, calling it the finest of monardas. Var. **salmònea,** Perry. Large heads of delicate shade of salmon-pink.—Suited to moister positions than the others.

AA. *Calyx densely bearded at the throat.*

B. *Lvs. petioled.*

fistulòsa, Linn. Wild Bergamot. Sometimes called bergamot in nursery catalogues, but the bergamot of the Old World is *Mentha odorata*. St. mostly obtusely angled: lvs. firmer: fls. purple, usually not so numerous as *M. didyma*. July, later than *M. didyma*. Var. **rùbra,** Gray. Fls. crimson or rosy red. Var. **mèdia,** Gray (var. *purpùrea*, Hort.). Fls. deep purple. Var. **purpùrea,** Pursh. The deep purplish crimson fls. are smaller. L.B.C. 14:1396. Var. **móllis,** Benth. (*M. móllis*, Linn.). Fls. flesh-color to lilac. B.M. 2958 (as *M. menthæfolia*).—Will grow in dry positions.

Ramàleyi, A. Nelson. Similar to *M. fistulosa* but softly and lanately white-pubescent, densely so at the nodes: lvs. lanceolate or narrowly ovate; petioles short, lanately pubescent as are also the midribs of the lvs.: involucral lvs. scarcely purple-tinged: corolla lavender. Cent. Colo.—This species is catalogued as being dwarf, 1–2 ft., bearing bright clover-red fls.

BB. *Lvs. nearly sessile, at least below.*

Bradburiàna, Beck. Fls. light purple, spotted darker on the middle lobe of the lower lip, which is much larger than the lateral ones. June. Ind. to Tenn. and Kans. B.M. 3310 (erroneously as *M. fistulosa floremaculata*).—Will grow in dry positions.

Wilhelm Miller.
A. C. Hottes.†

MONARDÉLLA (diminutive of Monarda, having its aspect, inflorescence and calyx). *Labiàtæ.* Annual or perennial sweet-smelling herbs, natives of California. Leaves entire or obscurely toothed: fls. rose, red, purple, or rarely, white, compacted in terminal heads with an involucre; calyx tubular, narrow or long, 10–13-nerved, 5-toothed; the teeth short, straight and nearly equal; the throat naked within; stamens 4, exserted.—About 15 species closely allied to Pycnanthemum and Origanum. The plants are best prop. by division in the spring. They prefer a sandy soil. The following have been advertised, and can be secured through western collectors.

A. *Fls. large, few, rather loosely glomerate.*

macrántha, Gray. Perennial, tufted, about 9 in. high: bracts of the 10–25-fld. head sometimes whitish or purplish tinged: corolla about 1½ in. long, glabrous, orange-red, its tube fully twice the length of the calyx; the lobes lanceolate. S. Calif.

nàna, Gray. Pubescent: 9 in. high: bracts whitish or rose-color: fls. smaller than *M. macrantha;* corolla less than an inch long, white tinged with rose, the slender tube pubescent. S. Calif., in mountains near San Diego.

AA. *Fls. smaller, more numerous, densely capitate.*

B. *Plants perennial.*

villòsa, Benth. Soft-pubescent, or the heads and lower face of lvs. villous, or sometimes the whole herbage glabrate, 9–12 in. high: lvs. ovate, all petioled; veins conspicuous, widely spreading. Woods and banks. W. Calif., especially along coast. Farther inland is a form (var. *interior*, Jeps.) with coarsely toothed lvs. and large heads.

odoratíssima, Benth. Cinereous-puberulent, or nearly glabrous: 9–12 in. tall: lvs. narrowly oblong to broadly lanceolate, entire or nearly so, short-petioled, or the upper subsessile, firm in texture; veins inconspicuous: bracts thin-membranaceous and colored (whitish or purple). Dry hills, Wash., Ore., and through higher mountains of Calif., Nev., Utah.—Odor of pennyroyal.

BB. *Plants annual.*

C. *Corolla rose-red or purple.*

lanceolàta, Gray. Lvs. oblong-lanceolate or narrower, tapering into a slender petiole: corolla rose-color or purple: bracts leafy. Calif.

CC. *Corolla white or nearly so, small and short.*

cándicans, Benth. Lvs. lanceolate or narrowly oblong, tapering into a slender petiole: bracts minutely pubescent outside, greenish along numerous nerves. Calif.

A. C. Hottes.†

MONÉLLA: *Cyrtanthus.*

MONÈSES (Greek, *single delight;* from the pretty solitary fl.). *Pyrolàceæ.* One-flowered Pyrola. One species, a low perennial herb: st. decumbent: lvs. roundish, clustered at base: fls. single, drooping, from top of slender scape 2–6 in. long, white or rose-colored, 6 lines across; petals 5, widely spreading, orbicular; filaments awl-shaped, naked; anthers as in Pyrola, but conspicuously 2-horned. **M. uniflòra,** Gray (*M. grandiflòra*, S. F. Gray. *Pýrola uniflòra*, Linn.), grows in moist cold woodlands from Labrador to Alaska, in middle states and westward along the mountains. It has been offered among native plants.

MONEYWORT, or **CREEPING CHARLIE,** is *Lysimachia Nummularia.*

MONKEY-FLOWER: *Mimulus luteus.*

MONKEY-PUZZLE: *Araucaria imbricata.*

MONKSHOOD: *Aconitum.*

MONOCHÆTUM (*one bristle*, referring to the connective). *Melastomàceæ.* Shrubs and subshrubs of tropical America, suitable for glasshouse culture, little grown.

Allied to Rhexia, but differing in the clavate-appendaged connective and other minor characters: mostly erect, pilose: lvs. 5–7-nerved, ovate or lanceolate: fls. paniculate, medium size, purple or rose; calyx-lobes 4, narrow, deciduous or persistent; petals 4; stamens 8, unlike, with glabrous filaments: fr. a 4-valved caps.—Species 30–40, Mex. to Peru. They are said to be of easy cult.; see *Melastoma* and *Medinilla* for similar plants. Prop. by cuttings.

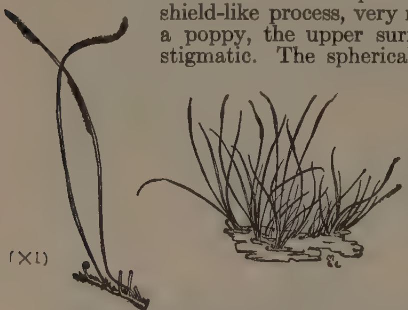
A number of species may be found in the collections of fanciers. Probably the one most likely to be cult., and which is now offered abroad, is **M. seríceum,** Hort. (probably *M. sericeum,* Naudin=properly *M. Bonplandii,* Naudin). There is also a garden var. *multiflorum* of it, with handsome mauve fls. produced in abundance in spring. *M. Bonplandii* is shrubby, the branches somewhat hirsute: lvs. ovate, 5-nerved, entire, short-petioled, villous, and pubescent beneath: fls. axillary or terminal, violet. S. Amer., in the Amazon region.

L. H. B.

MONOCHÒRIA (name refers to the *one separate* stamen). Sometimes misspelled *Monocharia. Pontederiàceæ.* A very few species of rhizomatous herbs allied to Pontederia but differing in the absence of perianth-tube, in erect rather than versatile anthers, and the ovary 3-celled and many-ovuled rather than 1-celled and 1-ovuled. The species are aquatic herbs in the tropics or subtropics of E. Asia, Afr., and Austral., with long radical and short cauline lvs., the blade cordate-ovate or lanceolate: raceme appearing to arise from the petiole of a scape-lf., bearing many blue or violet fls. Probably none is in the trade. *M. vaginàlis,* Presl, of India, bears long-petioled oblong-lanceolate cordate acute lvs. with hollow petioles and is eaten when young as a pot-herb: 2 ft. high: fls. blue. G.W. 11, p. 388.

MONODÒRA (Greek, *single gift,* in allusion to the solitary flowers). *Annonàceæ.* Trees, or shrubs, often with more or less climbing habit.

Flowers extra-axillary or opposite the lvs. or sometimes terminal, borne on a long bracteolate usually pendulous peduncle. This genus forms a distinct tribe distinguished from all other Annonaceæ by a 1-celled compound ovary with numerous ovules attached to the inner walls. The fls. are composed of 3 valvate sepals, a corolla of 6 petals united at the base, many short stamens crowded on a spheroid receptacle bearing 2 elongated parallel pollen-sacs capped by the dilated apex of the connective. The ovary borne on the summit of the receptacle expands into a shield-like process, very much like that of a poppy, the upper surface of which is stigmatic. The spherical gourd-like fr. is closely packed with seeds having the small embryo and wrinkled endosperm which is characteristic of all Annonaceæ. This genus though of African origin was first established from a plant growing in Jamaica, certainly intro. from Afr. with negro slaves. Of the 11 species described by Engler & Diels, all African, 2 are of economic importance. They are little known as horticultural subjects.



2384. Monogramma trichoidea.

Myrística, Dunal. CALABASH NUTMEG. Lvs. short-petioled, the blade firmly membranaceous or paper-like, glabrous, obovate or oblong-elliptical, cuneately narrowed toward the base, which is obscurely cordate; apex more or less acuminate, primary lateral nerves 10–20, prominent beneath, curving upward, connected by secondary nerves almost at right angles to them: fls. fragrant, solitary, long-pedunculate, the peduncle bearing at or above the middle an ovate-lanceolate or suborbicular bracteole often more or less acuminate at the apex; outer petals more or less ovate-lanceolate, gradually narrowing toward the apex, undulate-crispate, white or yellowish, and variegated with purple or brown spots; interior petals shortly clawed, ovate-cordate obtuse, auriculate and pilose at the base; stigma with the circular margin scalloped or entire: fr. globose, more or less longitudinally striate or obscurely ribbed, with the pericarp thick, woody and gourd-like, often 4–6 in. diam., and hanging on a peduncle 24 in. long. An African tree endemic in the forests of Sierra Leone, Upper Guinea, Kamerun, Gabun, the Lower Congo, and Angola. In its native habitat it often reaches a height of 60 ft. or more; but in cult. it is usually much smaller.—The aromatic seeds, with the endosperm ruminate like that of a nutmeg, are highly prized by the native Africans. They are used medicinally and as a spice for seasoning food, and are offered for sale in local markets, strung together like rosaries.

angolénsis, Welw. ANGOLA CALABASH NUTMEG. A shrub or tree sometimes reaching the height of 12 ft.: fls. very fragrant; outer petals undulate-crispate, variegated with purple, broadly ovate, erect and curving inward above the essential parts; inner petals rose-tinted or whitish in color, borne on a long narrow claw, dilated into a transversely elliptical or subrhomboid pilose limb: fr. is ovoid-ellipsoid, longitudinally striate and abruptly apiculate.—The aromatic seeds are used in the same way as those of the preceding species.

W. E. SAFFORD.

MONOGRÁMMA (Greek, a *single line;* alluding either to the grass-like lvs. or to the elongated linear sorus). *Polypodiàceæ.* A tropical Old World genus of several small species of grass-like ferns, rarely seen in cult. *M. trichoídea,* J. Smith (Fig. 2384), is a tiny bark-inhabiting plant with thread-like lvs., 1–2 in. long, native in the Philippines. It is of exceptional interest from the collector's standpoint because it is without exception, so far as known, the simplest and most delicate fern in existence. Its habitat is like that of most filmies and the cultural conditions required are also similar.

R. C. BENEDICT.

MONOLÈNA (Greek words referring to the single spur-like appendage on the anterior side of the anther-connective). *Melastomàceæ.* About 5 species of stemless somewhat fleshy herbs from Cent. Amer., Colombia and Peru, one of which is a small hothouse foliage plant, cult. like bertolonia, and known to the trade as *Bertolonia primulæflora.* All the species have a characteristic rootstock, composed of clusters of short thick rhizomes, prominently scarred by the falling of the lvs., and the fls. are numerous, and resemble a primrose about 1 in. across, 5-petaled, pink, and borne on slender scapes: lvs. long-petioled, oblong to orbicular, entire or dentate. See *Bertolonia.*

primulæflòra, Hook. f. (*Bertolònia primulæflòra,* Hort.). Glabrous: lvs. leathery, broadly elliptical, the margins dentate and ciliate: calyx-lobes broadly ovate-rounded. B.M. 5818. F.S. 18, p. 162. G.C. 1870:309. —It has metallic green lvs. 4–6 in. long, with 3–5-parallel veins, the under surface of the lvs. being a showy rosy purple.

MONOLÒPIA (Greek, *one garment* or *husk;* referring to the involucre, the scales of which are united at base or into a cup). *Compósitæ.* Yellow-fld. woolly annuals from Calif., with 8–10 pistillate rays which are 2–4-toothed or lobed: lvs. alternate (or lower ones opposite), sessile, entire or pinnately parted: peduncles terminal, solitary, 1-fld.; heads large, many-fld.; some of the disk-rays sterile; lobes of disk-corollas somewhat bearded and ray-fls. with appendage at base of ligule; pappus none.—Species perhaps a half-dozen; of minor importance horticulturally.

màjor, DC. (*Helènium Doúglasii*, Hort.). Small and woolly in the wild, green and 2–3 ft. high in cult.: lvs. entire or somewhat toothed, sessile, linear to broadly lanceolate: fls. 2 in. across, yellow; rays dilated, coarsely 3–4-toothed, appendaged at the base. B.M. 3839.—Said to bloom most of the summer. Lvs. 3–5 in. long, reflexed: rays 8–9, fertile, short, broad and coarsely toothed, bright golden yellow.
L. H. B.

MONOMÉRIA (*one part*, referring to the single anther). *Orchidàceæ*. Two epiphytic orchids from India, allied to Bulbophyllum, little cult. Pseudobulbs 1-lvd., on a stout rhizome, the lf. long, thick and flat: scape arising from the rhizome and bearing a loose raceme; petals minute, fimbriate; dorsal sepal broad and erect, the lateral much longer; lip small, jointed on the column-base, subcordate; column very short, 3-toothed; anther 1-celled; pollinia 4. *M. barbàta*, Lindl., has scape about 1 ft. long, and fls. about 1¼ in. long, greenish marked red-brown. Sikkim.

MONÓPANAX: *Oreopanax*.

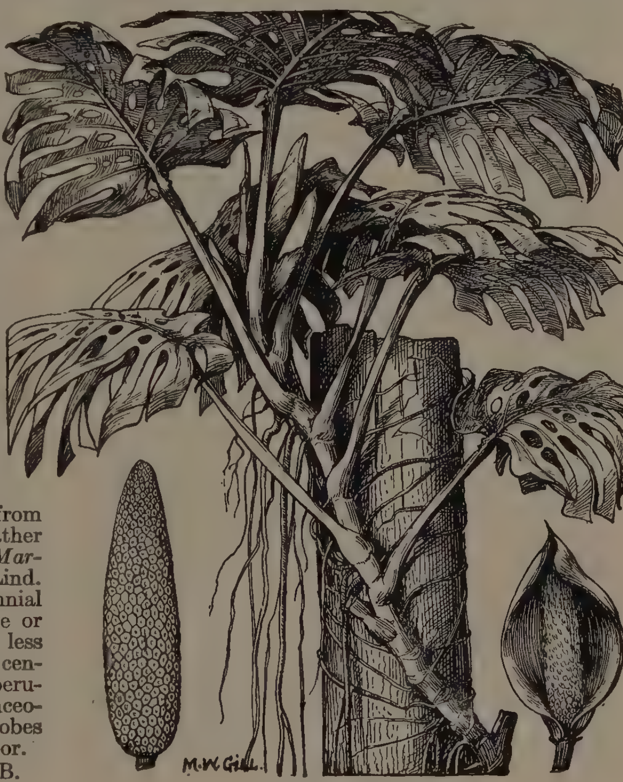
MONOTÁGMA (*single row* or *series*, from the Greek). *Marantàceæ*. Maranta-like plants, about 10 species, in S. Amer., one of which is in cult. It belongs to the 1-loculed section of the family, with a single staminodium; differs from Ischnosiphon, among other things, in its solitary rather than geminate fls. **M. smarágdinum**, Schum. (*Marànta smarágdina*, Lind. *Calathèa smarágdina*, Lind. *Ischnosìphon smarágdinum*, Eichl.). Erect perennial showy herb, 1–1½ ft.: lvs. long-petioled, lanceolate or oblong-lanceolate, acuminate, the base more or less rounded, emerald-green above with a dark green central stripe, beneath pale green and minutely puberulent: fls. 4–8, solitary, disposed in spikes; sepals lanceolate; corolla-tube much exceeding calyx, the lobes lanceolate and obtuse; staminode obovate. Ecuador.
L. H. B.

MONSÒNIA (named for Lady Ann Monson, correspondent of Linnæus). *Geraniàceæ*. Erect or decumbent herbs or shrubs, sometimes grown under glass as are pelargoniums.

Annual or perennial, mostly with slender sts.: lvs. alternate or opposite, crenate-dentate or dissected, stipulate: peduncles axillary or rarely nearly basal, bracteate, 2- to many-fld., or rarely 1-fld. by abortion; fls. white, rose-colored, red, purplish, regular; sepals and petals and glands 5; stamens 15, all fertile, connate at base; ovary 5-lobed and 5-celled, beaked: valves of fr. 1-seeded, revolutely dehiscing.—Species 29 as accepted by Knuth in Engler's Das Pflanzenreich, hft. 53 (1912), African, 2 or 3 extending into Asia. Probably the species most likely to be met with in cult. are *M. lobàta*, Mont., and *M. speciòsa*, Linn. f., suffruticose plants 1 ft. or so high, from S. Afr. The former has lvs. cordate and 5–7-lobed, and fls. greenish and variegated outside and pale bluish inside with darker center. B.M. 385. The latter has lvs. palmately 5-parted and lobes 2-pinnatifid, and fls. rose-colored with darker eye. B.M. 73.
L. H. B.

MONSTÈRA (name unexplained by the author; probably from the Latin for *strange* or *monstrous*). *Aràceæ*. Root-climbing evergreen aroids from tropical America, of which one, *Monstera deliciosa*, is often grown under glass for its odd foliage and in the tropics for its edible fruit.

Woody, the branches rooting, the roots often cord-like, the lvs. more or less distichous: lvs. often very large (small on juvenile shoots and more regular), from lanceolate to oblong and broader, entire, perforated or pinnatifid, the petiole prominent and sheathing: peduncles terminal, solitary or fascicled, bearing ovate or oblong boat-shaped spathe that opens widely after flowering and finally is deciduous: spadix shorter than the spathe, cylindrical or nearly so, densely flowered, bearing the hermaphrodite or perfect fls. above and sterile fls. below; fertile or perfect fls. with no perianth, and 4 stamens, and a 2-celled ovary with 2 ovules in each cell: frs. many small berries, crowded or joined into a multiple fr. or cone-like structure.—Species 27 as monographed by Engler & Krause in Engler's Pflanzenreich, hft. 37 (1908).



2385. Monstera deliciosa.

The species commonly known in horticulture is *Monstera deliciosa*, the ceriman (Fig. 2385). It is a greenhouse climber, with huge perforated leaves. As the plant climbs, the stems emit long aërial roots, many of which never reach the ground. The plant bears an edible fruit, which has a taste between a pineapple and a banana. The fruit grows about 6 to 8 inches long, and looks like a long pine-cone, the rind being composed of hexagonal plates. The monstera is a satisfactory greenhouse subject, even in a young stage, and being a great curiosity, excites much comment from visitors. It is usually kept in a hothouse, but succeeds in a coolhouse also. It is commonly allowed to grow in a spreading rather than climbing fashion. As a conservatory plant it does best when planted out in a bed of rich soil, where it can be kept within bounds by judicious pruning. It is not particular as to soil, as it fills the pots in which it is planted with thick succulent roots in a very short time. It is one of the best plants for enduring the varying conditions of temperature in a dwelling-house, as nothing short of a freeze seems to hurt it.

The propagation of monstera is easily accomplished by division of the growing stems. These can be cut up into lengths so as to include two or three joints placed in a propagating-bed with bottom heat of 75° to 80°. A good method is to place each cutting in a 3-inch pot, filled with a mixture of sand, peat and leaf-mold in equal parts. Plunge the pots up to the rims in a warm propagating-bed and cover with glass so as to insure a humid atmosphere. When they have made new roots they can be taken out of the propagating-bed and placed on a bench in a house, with a night temperature of 65° to 70° with a rise during bright days to 80° or 85°. While they will grow in 8 to 10° cooler temperature, they will never come to their full perfection without plenty of heat. As the pots become filled with roots, they should be shifted until the plants are in 10- or 12-inch pots or tubs. They may also be planted out along some wall or pillar in the greenhouse. Monsteras are tropical climbers, so will need some mode of support to keep them growing in their natural habit. For a compost they like a turfy soil three parts, leaf-mold and well-rotted manure one part each; to this add enough sand to make it porous. Give plenty of ventilation. They should be syringed frequently during the spring, summer and fall months. During the summer, they require plenty of water to keep up their vigorous growth. When monsteras are wanted to ramble over a large area, they should be given much liquid feeding. They will need a little shade during the hottest part of the summer, but no more than is necessary to hold the foliage in good color, as it only tends to make them grow soft and flabby. During the winter months, it is always better to lessen the water-supply as they are in a state of dormancy until about the end of January when they will show renewed state of activity. These plants are not troubled with many insects. The texture of their leaves will allow syringing to such an extent as to dislodge any kind of pest. (J. J. M. Farrell.)

In the American tropics *M. deliciosa* requires a very warm moist climate for the production of fruit. Although it naturally grows by attaching itself to trees and creeping up, it appears to be more fruitful if compelled to grow on the ground without climbing. The fruit is green in color until it ripens, when there is just a tinge of yellow, and the outer rind comes off in bits at a touch.

The plant known to the trade as *Marcgravia paradoxa* is *Monstera dubia*. The adult leaves are something like those of *M. deliciosa*, being now and then perforated, but usually pinnately cut. The young leaves are very different, being much smaller, entire and heart-shaped. In its young stage, *M. dubia* is a very handsome hothouse climber, with thick roundish waxy leaves, which grow in two ranks and overlap one another. When the plant was introduced by Bull, it was shown growing on a board apparently in parasitic fashion, and emitting aërial roots. It seemed most like a Marcgravia, but when it flowered and fruited the first name was found to be incorrect. Marcgravia is a dicotyledon and Monstera a monocotyledon. The monstera-like leaves are likely to be developed when the plant reaches 15 feet. In the young stage the plant is generally allowed to clamber over a dead log or tree-fern trunk, in the manner of Philodendron, which see for culture.

deliciòsa, Liebm. (*M. Lénnea*, Koch. *Philodéndron pertùsum*, Kunth & Bouché). CERIMAN. Fig. 2385. Sts. strong, terete, climbing high: lf.-blades 1–2 ft. and more long, leathery, pinnately cut, perforated, the petiole very long. Mex., Guatemala. A.F. 7:253. G.M. 41:329. Gn. 21, p. 39.

dùbia, Engler & Krause (*M. ténuis*, C. Koch. *Marcgràvia dùbia*, Kunth. *M. paradóxa*, Bull). SHINGLE PLANT. Young lvs. a few inches long, waxy, entire; mature lvs. pinnatifid, the segms. narrow-linear and acute. Mex. Gn. 29, p. 290 (both kinds of lvs.). G.C. II. 8:13.

latevaginàta, Engler & Krause (*Pòthos celatocaùlis*, N. E. Br.). Sts. flat on under side, lying close to support: early lvs. distichous and overlapping, broad-elliptic, sessile, dark velvety green, appressed to support; older lvs. larger, lobed, free. Trop. Amer. F.S. 23:2419, 2420. I.H. 30:496. L. H. B.†

MONTANÒA (Montano, a Mexican statesman). Sometimes spelled *Montágnæa*. *Compósitæ*. Shrubs or even small trees, pot-plants being used sometimes for subtropical bedding and for winter bloom; somewhat allied botanically to Rudbeckia.

Strong mostly robust plants, mostly pubescent or tomentose: lvs. opposite, entire, dentate or even pinnatifid: heads small or medium, corymbose-paniculate, heterogamous, radiate; ray-florets neutral, in 1 series; disk-florets perfect but the innermost sterile; receptacle convex or conical, with carinate scales about the fls.; corolla white or rose-colored.—About 20 species, Mex. to Colombia. They are of easy cult.; the seeds are started indoors and the plants may be transferred to the open for foliage effects, as are melianthus, the large solanums and others; prop. also by cuttings. Several of the species are likely to appear in collections in subtropical gardens.

bipinnatífida, Koch (*Polýmnia grándis*, Hort.). Erect and strong, half-shrubby, to 8 ft.: lvs. pinnatifid or 2-pinnatifid, more or less hairy, the segms. serrate or notched: heads 3 in. diam., with showy pure white rays. Mex. G.C. III. 39:123; 42:419. Gn. 72:308. G. 30:277. G.M. 50:903. R.H. 1910, p. 175.—A striking subject either for winter bloom indoors or for bedding out with bold planting.

mollíssima, Brongn. Branching shrub, more branching and stiffer than *M. bipinnatifida*, 6 ft., the branches pubescent but becoming almost glabrous: lvs. lanceolate or ovate-lanceolate, about 6 in. long, sessile, dentate, white-tomentose beneath, veiny, soft to the touch: heads 1½ in. diam. on long peduncles, the rays about 9 and white, the disk yellow. Mex. B.M. 8143.—This and *M. grandiflora*, DC., are confused, but the latter (which may be in cult.) has very rough and scabrous lvs. that are brown-hairy beneath; what is known in cult. as *M. grandiflora* is probably diverse. Mex. G.C. III. 43:40. Gn. 74, p. 623.

Wércklei, Berger. A recent species from Costa Rica: shrub, to 20 ft., the branches white-tomentose: lvs. petioled, 5–7-lobed or trifoliolate or unequally pinnate, soft-pubescent, 8–10 in. long, the lfts. small: heads about 2 in. across, probably white, in broad corymbs. L. H. B.

MONTBRÈTIA: *Tritonia.*

MONTEREY CYPRESS: *Cupressus macrocarpa.*

MONTEREY PINE: *Pinus radiata.*

MÓNTIA (Guiseppe Monti, professor of botany at Bologna in the first half of the eighteenth century). *Portulacàceæ*. Small glabrous herbs, grown for ornament and one as a salad or pot-herb; annual and perennial.

Leaves opposite, fleshy: fls. minute, nodding solitary or loosely racemed, white, or pale rose-color; sepals 2 (rarely 3), broadly ovate, persistent; petals 3, more or less united; stamens 3 (rarely 5), inserted on the corolla; ovary 3-ovuled; style short, 3-parted: caps. 3-valved, 3-seeded; seeds nearly orbicular, compressed, minutely tuberculate.—About 18 species of American herbs, including the winter purslane, a salad or pot-herb known to the European trade as *Claytonia perfoliata*. This odd plant is perhaps cult. in Amer. by a few fanciers of rarer kinds of vegetables. In hot countries it may be more desirable. The most remarkable feature is a sort of cup an inch or more in diam., from which arise the racemes of small white or rose-colored fls. One of these cups crowns each of the sts., which are numerous, slender, leafless, and about twice as long as the lvs. The name "perfoliata" is suggested by the resemblance of the cup to a perfoliate lf. In *M. perfoliata* the cup is usually 2-lobed; and the species runs into *M. parviflora*, which rarely has the cup transformed into 2 almost disjoined lvs. *M. fontana* is the aquatic or semi-aquatic species found in most of the temperate regions of the world. The winter purslane is now a weed in many parts of the world. The seed may be sown all through spring and summer where the plants are to stand. Montia cannot be distinguished from Claytonia by any one character, but the cult. plants of both genera have been sufficiently discriminated here and under Claytonia.

A. *Sts. without true lvs.*

perfoliàta, Howell (*Claytònia perfoliàta,* Don). Winter Purslane. Rather coarse, green, often reddening with age: radical lvs. from subreniform to spatulate-obovate, often 1–3 in. broad; cauline lvs. merely flattened disks: pedicels not longer than the fruiting calyx; petals white, little surpassing the calyx. Banks of streams, Calif. to Ariz. and Mex., north to Brit. Col.; common near Pacific coast. It grows wild in Cuba but is not native there, as often stated. B.M. 1336. R.H. 1897, p. 159. Annual.

parviflòra, Howell (*Claytònia parviflòra,* Douglas). More slender, green or slightly glaucous: radical lvs. spatulate to filiform-linear: pedicels slender, much longer than calyx; petals white or pale rose-color hardly double length of calyx. Calif. to Brit. Col., east to Idaho and Utah. Annual.

AA. *Sts. leafy.*

B. *Lvs. alternate, numerous, small.*

parvifòlia, Greene (*Claytònia parvifòlia,* Moc.). Sts. a span to a foot long, ascending or some procumbent, sometimes reduced to naked runners: radical and lower cauline lvs. rhomboid-obovate, about ½in. long, contracted at base into a slender petiole; upper narrower and small: fls. few and racemose, rose-color varying to white. The plant has bulb-like offshoots in the axils of the cauline lvs. Moist rocks, Brit. Col. to Rockies in Mont. and Alaska.—Of very little ornamental value. Apparently perennial.

BB. *Lvs. opposite.*

fontàna, Linn. Water or Blinking Chickweed. Blinks. Water-Blinks. Densely tufted, very green, weak, diffuse or ascending, 1–6 in. long, freely branching: lvs. spatulate or obovate, mainly obtuse, ⅛in. broad or less: fls. nodding, solitary and terminal or in a small, loose, leafy-bracted raceme; sepals obtuse, slightly shorter than the petals: caps. globose, nearly ⅛in. diam.—Wet places, Que., Maine, Nova Scotia, Newfoundland, mountains of Calif. Summer. Annual, or perennial by rooting at the nodes. A. C. Hottes.†

MOON DAISY: name used in England for *Chrysanthemum Leucanthemum* and other species. See page 754.

MOONFLOWER in America always means *Calonyction aculeatum* and related species; in England it rarely, if ever, means this, but *Chrysanthemum Leucanthemum.* Moonflower in England also means sometimes *Anemone nemorosa* and *Stellaria Holostea.*

MOONSEED: *Menispermum canadense.*

MOONWORT: *Botrychium;* also *Lunaria.*

MOÒREA (named in 1890 for F. W. Moore, curator of the Glasnevin Botanic Garden, Ireland). *Orchidàceæ.* One handsome warmhouse orchid, something like Houlletia, from which it differs in the lip having no claw and being articulated with the foot of the column and the midlobe or epichile not articulated with the hypochile.

irroràta, Rolfe. Pseudobulbs ovoid, to 3 in. high: lvs. 2, plicate, to 2 or 3 ft. tall and 8 in. broad: scapes much shorter than or equaling the lvs., several- to many-fld.; fls. about 2 in. diam., the sepals and petals red-brown and whitish at base; lip smaller, 3-lobed, straw-yellow with dark purple lines, the crest bright yellow; column stout and incurved; pollinia of 2 unequal pairs. Probably Colombia. B.M. 7262. G.C. III. 11:489; 29:248. J.H. III. 42:277. G.W. 15, p. 431.—The cult. is similar to that for houlletia; to be potted in a mixture of peat, sphagnum and a little fibrous loam; should be rested after growth. It is easily grown and free-flowering, doing well in a cattleya house. L. H. B.

MOOSEWOOD: *Dirca palustris* and *Acer pennsylvanicum.*

MORÆA (from a personal name). *Iridàceæ.* Morea. Charming bulb plants much like irises, but they are not so hardy as the common irises and the individual flowers last only a day or so; of interest to amateurs.

Mostly having corms except in subgenus Dietes which has a short rhizome: perianth-tube obsolete; outer segms. obovate-cuneate, with a reflexing limb; inner similar, smaller; stamens with anthers like those of Iris, but filaments more or less connate; ovary, style, caps., and seed as in Iris: lvs. few, linear or ensiform: fls. 2 or more, clustered, various in color, usually fugitive.—About 60 species, 45 of which are S. African, while the others are chiefly from Trop. Afr., one species being found in Austral. Moræa is the African representative of Iris. No one character will separate the two genera. Moreas have no perianth-tube, while irises usually have one. The filaments are usually monadelphous in Moræa and free in Iris. Irises grow either from rhizomes or bulbs, while moreas mostly grow from corms, except the subgenus Dietes, which grows from a rhizome. Most of the showiest moreas belong to the subgenus known as Moræa proper. There is another subgenus which differs from it in having the ovary extended into a long beak which looks like a perianth-tube, but none of this group is cult. The moreas proper are about as tender as other Cape bulbs. The amateur may find some suggestions as to their cult. under *Bulbs, Iris* and *Ixia.*

By far the largest and most remarkable plant of the genus is *Moræa Robinsoniana.* This grows 6 to 8 feet high and has the habit of the New Zealand flax, *Phormium tenax.* A splendid specimen mentioned in B.M. 7212 bore 457 flowers between June 20 and October 1. The individual flowers are 4 inches across, fragrant and last only a day. At Kew this noble plant has been successfully grown in the south end of a house. The stately plant pictured in G.F. 10:255 grew in a Californian garden and was said to be sixteen years old from seed. The finest picture, however, is that in G.F. 4:355.

A. *Rootstock a corm, tunicated: ovary not beaked.*

B. *Inner segms. conspicuous.*

C. *Plants dwarf, 4–6 in. tall.*

D. *Lvs. hairy all over.*

1. **papilionàcea,** Ker. Very dwarf, 4–6 in. tall: fls. red or lilac, yellow on the claw; style-crests erect: sts.

simple or forked low down, bearing 1–6 clusters on short erect peduncles: lvs. hairy all over, linear, 3–6 in. long: caps. oblong, ⅓in. long. S. Afr. B.M. 750.

DD. *Lvs. hairy only at edges.*

2. **fimbriàta,** Klatt. Very dwarf, 4–6 in. tall: fls. lilac: sts. simple or forked low down, bearing 1–4 clusters on erect peduncles: spathes 2–3-fld.: lvs. 3–10 in a basal tuft, linear, much crisped, hairy at edges: caps. oblong, ⅓in. long. Cape Colony.

CC. *Plants above 6 in. tall.*

D. *St. provided with 1 wiry lf. just below infl.*

3. **edùlis,** Ker. Fls. lilac, spotted yellow: st. naked except for one long wiry lf. from base of infl.: caps. cylindrical. S. Afr. B.M. 613. Var. **odòra** has white fls. Var. **longifòlia** has yellow fls. B.M. 1238.

DD. *Sts. with 1–2 produced lvs. somewhat distant from infl.*

E. *Fls. lilac.*

F. *Lvs. above 8 in. long.*

4. **trístis,** Ker. Lvs. 2–3, produced near the base, 1–2 ft. long: clusters of fls. 4–6; fls. dull lilac, ochre or salmon-colored, with a yellow spot; style-crests lanceolate: caps. oblong. Cape Colony, southwest district. B.M. 577 (*Iris tristis*).

FF. *Lvs. less than 8 in. long.*

5. **Thómsonii,** Baker. A rigid herb of rush-like habit: lvs. terete, 6-furrowed: fls. 1¾ in. diam. in spicately arranged fascicles; perianth lilac, yellow at base, spotted brown, midribs darker lilac inside, reddish brown outside. E. Trop. Afr. B.M. 7976.

6. **júncea,** Linn. Fls. lilac, in 2–3 clusters: lvs. 2–3 in. long, falcate, linear complicate: st. very slender, 6–8 in. long: ovary oblong. Cape Colony.

7. **polyánthos,** Thunb. Lvs. about 3, one from near the base of the st., the others from the lower forks, ½–1 ft. long: clusters of fls. 5–20; fls. lilac: caps. clavate or oblong, ⅓–½in. long. Cape Colony, northward to Transvaal.

EE. *Fls. bright yellow.*

8. **revolùta,** C. H. Wright. Closely allied to *M. spathacea:* sepals revolute; styles crested, crossed like closed tips of wings of some birds; fls. solitary; petals oblanceolate, 2½ in. long, bright yellow. Angola.

9. **spathàcea,** Ker. Lvs. 1 only produced, strongly ribbed, 1½–2 ft. long: st. stout, 2–3 ft. long: spathes 2–4-fld.; perianth bright yellow; crests large, lanceolate. Cape Colony. B.M. 6174 (*Dietes Huttoni*).

BB. *Inner segms. inconspicuous.*

C. *Color of fls. chiefly orange-red.*

10. **Pavònia,** Ker (*Ìris Pavònia,* Linn. f.). Outer segms. without a distinct claw, orange-red, with a blue-black or greenish black spot at the glabrous base: lvs. narrow, linear, usually pilose: spathe-valves scariose at the tip. B.M. 1247. Var. **villòsa,** Ker (*Ìris villòsa,* Ker). Lvs. pilose: outer segms. bright purple, with a blue-black spot and a hairy claw. B.M. 571 (*Iris villosa*). Var. **lùtea,** Baker. Lvs. glabrous: fls. yellow, unspotted. B.M. 772 (*Moræa tricuspis* var. *lutea*). Cape Colony, southwest district.—In *M. Pavonia* and *M. glaucopis* the inner segms. have a large central cusp and 2 lateral lobes, while in *M. tricuspis* the inner segms. have 3 large cusps.

CC. *Color of fls. chiefly white.*

D. *Spotted blue.*

11. **glaucópis,** Drap. Outer segms. white, with a blue spot: produced lf. single, long, narrow, linear: st. 1½–2 ft. long; usually 1–3-branched: caps. clavate: crest large, lanceolate. Cape Colony, southwest district. B.M. 168 (erroneously as *Iris Pavonia*).—In this species the outer segms. have a short, distinct claw, while *M. Pavonia* has none.

DD. *Spotted brown.*

12. **tricúspis,** Ker. Outer segms. whitish or lilac, with a purplish spot: produced lf. single, long, firm, narrow: st. 1–2 ft. long, with 2–3 sheath-lvs., usually with 3–4 erect branches: spathe-valves scariose at tip: caps. clavate. Cape Colony, southwest district to Natal. B.M. 696.

AA. *Rootstock a rhizome, short, creeping.*

B. *Color of fls. chiefly white.*

C. *Height of plant 6–8 ft.*

13. **Robinsoniàna,** Moore & Muell. (*Ìris Robinsoniana,* Muell.). WEDDING IRIS. Rhizome short: lvs. radical, 5–6 ft. long: fl.-st. 5–6 ft. long; fls. laxly corymbose; perianth pure white, outer segms. spotted red and yellow near base; crests short and broad. Lord Howe's Isl., Austral. B.M. 7212. G.F. 4:355; 10:255. J.H. III. 32:569. G.M. 34:569. G.C. 1872:393; III. 9:457.

CC. *Height of plant 1–2 ft.*

14. **iridioìdes,** Linn. St. 1–2 ft. long, with many short, sheathing, lanceolate bracts: lvs. in fan-shaped basal rosettes: fls. over 3 in. across, white, marked yellow on claws of outer segms.; style-crests lanceolate, ⅓–½in. long, marked with blue. In Calif. this species is very satisfactory, blooming once a fortnight from early spring until Nov. S. Afr. B.M. 693. L.B.C. 19:1861 (*Iris crassifolia*). G.C. III. 43:88. G.L. 26:92. Vars. **Mácleaii,** Hort., and **prolongàta** are garden forms. Var. **Jóhnsonii,** Hort. Differs from type in having longer lvs., 2½ ft. long, erect, instead of spreading obliquely: fls. 4 in. across. G.C. III. 41:296.

BB. *Color of fls. chiefly yellow.*

15. **bícolor,** Steud. Habit of *M. iridioides:* fls. 2 in. across, yellow, with beautiful brown spots on the outer segms.; style-crests yellow: lvs. 1½–2 ft. long: sts. 1–2 ft. long: style-crests small. Cape Colony, southeast district. B.R. 1404. L.B.C. 19:1886. P.M. 9:29 (all as *Iris bicolor*). R.B. 33:21.

M. sinénsis, Hort. Fl.-sts. 15 in.; fls. 1½ in. across, golden yellow, spotted and streaked vivid scarlet and orange: seeds abundantly. G.C. III. 51:37. May be the same as Belemcanda chinensis, Leman., the blackberry lily.—*M. Sisyrinchium*=Iris Sisyrinchium.

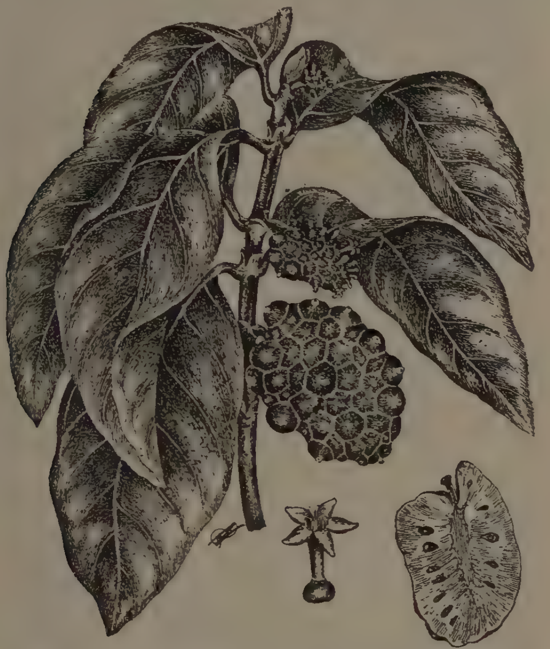
WILHELM MILLER.
A. C. HOTTES.†

MORÈNIA (G. Moreno, physician and naturalist in Lima). *Palmàceæ.* Closely akin to Chamædorea, but distinguished by the 3-toothed rather than disk-like or ring-like calyx in the male fl. Species Andine, about a half-dozen, very little known in collections. *M. corállina,* Karst., has an annular slender erect st. to 20 ft. high: lvs. pinnate, the lanceolate straight lfts. about 24 pairs: fls. white becoming pale yellow, slightly sunk in the spadix; petals 3 and stamens 6: berry ⅔in. diam., bright pink. Colombia. B.M. 8527. *M. fràgrans,* Ruiz & Pav. About 6 ft., graceful: lvs. ovate, the petiole long-sheathing at base; lfts. 1 ft. long, narrow-lanceolate, acuminate, unarmed: spadix nodding, 1 ft. long, the branches white. Peru. B.M. 5492.

MORICÁNDIA (named for Moricand, an Italian botanist). *Cruciferæ.* A few herbs or little shrubs of the Medit. region, seldom cult., allied to Brassica. Erect, very glabrous and glaucous, branching: lvs. entire or pinnatisect: fls. large, purple or rose: pod elongated, on strict pedicels. Only one species is likely to be cult., *M. arvénsis,* DC. This is annual or biennial, 12–18 in. high, with entire lvs., the cauline cordate and clasping, the lower ones oblong: fls. terminal, in spring and summer, violet with darker lines, attractive. S. Eu. B.M. 3007. G. 35:707. Seeds sown in early spring give plants blooming in midsummer.

MORÌNA (Louis Morin, a French botanist, 1636–1715). *Dipsàceæ.* Perennial herbs, suitable for borders and rock-gardens.

Somewhat thistle-like or resembling spiny plants of the Labiatæ, glabrous or pubescent: lvs. opposite or whorled, narrowly oblong or linear, mostly spinous-toothed: fls. whorled in spikes, the whorls with wide lf.-like bracts, and with spinous bracteoles among the fls.; calyx 2-lipped, the lips entire or 2-lobed; corolla 5-lobed and somewhat 2-labiate, the tube curved; stamens 2 or 4, and sometimes a sterile one.—About 10 species, in Asia, allied to Cephalaria and Dipsacus.



2386. Morinda citrifolia branch with leaves, flowers and fruit Also vertical section of fruit (fruit sometimes larger) and enlarged flower below. (×½)

A. *Fls. mostly white.*

Bulleyàna, Forr. & Diels (*M. Beesiàna,* Hort.?). St. 1–2 ft., hairy in stripes: lvs. linear to ovate-lanceolate, spiny-dentate, 5–6 in. long: fls. subcapitate, white or purple; calyx spathaceous, entire, spinose at mouth. China. Recent.

AA. *Fls. yellow.*

Coulteriàna, Royle. St. 2–3 ft., more or less hairy: lvs. 6 in. long and less than 1 in. wide, sessile, glabrous, spinous-toothed: fls. yellow, the corolla-tube to ¾in. long; calyx-lobes nearly equal and bifid, sharp or spiny; fertile stamens 2. India, 9,000–13,000 ft. in the Himalayas.

AAA. *Fls. pink or purple.*

pérsica, Linn. (*M. túrcica,* Hal. *M. græca,* Jaub. & Spach). Thistle-like: st. 3–4 ft., pubescent or hairy: lvs. 6 in. long and 1 in. wide, sessile, doubly spinous-toothed, pubescent or glabrous: spikes long, bearing bright pink fls.; calyx-lobes nearly equal, entire or emarginate; fertile stamens 2, the filaments as long as corolla-lobes; corolla-tube to 1½ in. long. Greece to the Himalayas.

longifòlia, Wall. St. 3–4 ft., pubescent or hairy: foliage thistle-like; lvs. 6 in. long, 1 in. across: fls. showy, deepening from white in the bud to pink and finally crimson, crowded in dense whorls near the top of st.; calyx-lobes unequal, 2-lobed with obtuse not spinous lobes; fertile stamens 2, the filaments much shorter than the corolla-lobes. Himalayas, 9,000–14,000 ft. Hardy. June–Aug. Himalayas. B.M. 4092. B.R. 26:36. R.H. 1857, p. 514. G.W. 7, p. 5. H.U. 1, p. 191. J.H. III. 51:127.—Whorl-flower is a catalogue name. A useful plant.

L. H. B.

MORÍNDA (Latin, *morus,* mulberry, and *indica,* Indian). *Rubiàceæ.* Woody plants, sometimes seen far South; one species has been planted in southern Florida and southern California.

Shrubs, trees and climbers in Trop. Asia, Austral. and the Pacific Isls., and some in Trop. Amer., perhaps 60 species now described: lvs. opposite, rarely in 3's; fls. white or crimson, in axillary or terminal, simple, panicled or umbellate heads; corolla-tube short or long, funnelform or salverform; lobes 4–7, coriaceous, valvate in the bud; stamens 4–7, usually 5, the filaments adnate to throat of corolla; ovary 2–4-celled, the styles united: fr. an aggregate of the ovaries, or berries, in the head.—Some of the species yield dyes. The frs. of some of them are edible. One species, *M. Roioc,* Linn., is native in Fla., extending to the W. Indies; it is a branching shrub with prostrate or somewhat climbing sts.

citrifòlia, Linn. INDIAN MULBERRY. Fig. 2386. A small tree, with smooth bark and obtusely 4-angled branches: lvs. short-petioled, to 10 in. long, broadly elliptic, shining, acute or obtuse: stipules large, broadly oblong or semi-lunar: fl.-head on solitary peduncles 1 in. long usually in the axil of every other pair of lvs. or lf.-opposed; calyx-limb truncate; corolla 5-lobed, tube about ½in. long: fr. yellowish, fleshy, globose or ovoid, about 1 in. diam. Probably India; also Malay Archipelago to Austral. and islands. G.C. II. 11:333.—The fls. contain a red and the roots a yellow coloring principle.

Var. **bracteàta,** Hook. Stipules more acute: calyx-limb often with a lanceolate or spatulate white leafy lobe, sometimes 3 in. long.

M. B. COULSTON.
L. H. B.†

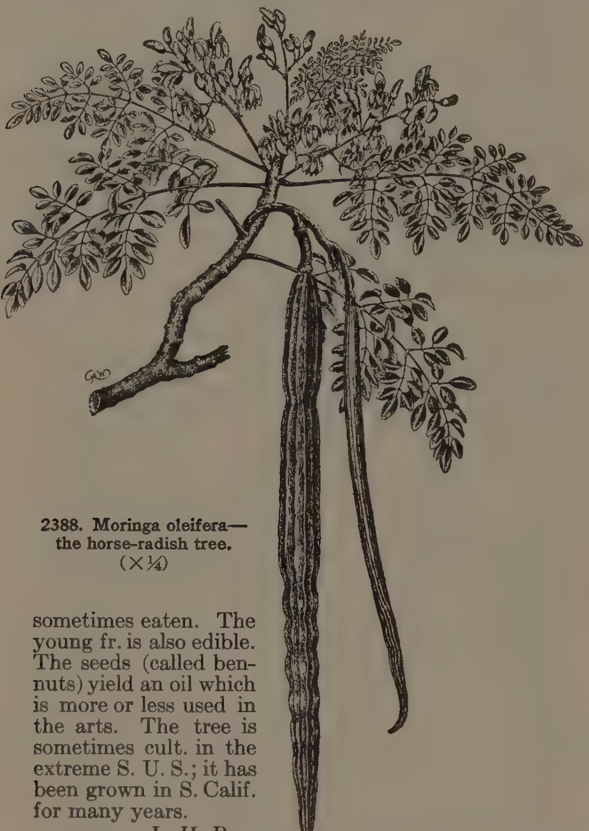
MORÍNGA (altered from the native Malabar name). *Moringàceæ.* Trees of warm countries, one of which is run wild in W. Indies and planted in southernmost parts of the United States.

Flowers perfect, 5-merous; calyx cup-shaped, 5-cleft, the lobes reflexing; petals 5, one of them erect and larger; fertile stamens 5, alternating with 5 or 7 staminodia, the anthers attached on the back, and 1-loculed: fr. a long, 4–9-angled, 1-loculed pod with 3 valves, the seeds immersed in the spongy contents of the valves.—Only three species comprise the family Moringaceæ, all members of the genus Moringa. They are small spineless trees, with alternate deciduous pinnate lvs., axillary panicles of rather large, white or red fls., and long pod-like frs. They are native of N. Afr. and the tropical parts of Asia. The position of the family Moringaceæ is difficult to determine. Bentham & Hooker ally it with Anacardiaceæ. Engler & Prantl place it between Resedaceæ and Sarraceniaceæ. Grisebach joins it to the Capparidaceæ. Others ally it with the Leguminosæ, which it resembles in external appearance.

oleífera, Lam. (*M. pterygospérma,* Gaertn.). HORSE-RADISH TREE. BEN. Figs. 2387, 2388. Small tree (reaching 25 ft.), with soft wood and corky bark, the young parts pubescent: lvs. mostly 3-pinnate, ¾–2 ft. long, all parts stalked: fls. whitish, stalked, fragrant, 1 in.

2387. Moringa oleifera (About natural size) across: pod often 1½ ft. long, 9-ribbed, bearing 3-angled, winged seeds. India, but now spontaneous in parts of the W. Indies.—The horse-radish tree is so named from the pungent taste of the root, which is sometimes eaten. The young fr. is also edible. The seeds (called ben-nuts) yield an oil which is more or less used in the arts. The tree is sometimes cult. in the extreme S. U. S.; it has been grown in S. Calif. for many years.

L. H. B.



2388. Moringa oleifera—the horse-radish tree. (×¼)

MORÍSIA (G. G. Moris, 1796–1869, Italian botanist). *Cruciferæ.* One perennial, excellent in alpine gardening, from Corsica and Sardinia, **M. hypogǽa,** Gay. Fig. 2389. Sts. short or none, the underground part spreading horizontally and sending up many linear, pinnatisect or pinnatifid lvs. 3 in. long: fls. golden yellow, in spring and early summer, solitary but numerous and large (¾in. diam.); sepals erect, linear-oblong and obtuse; petals spatulate: scape decurving and burying the fr., the latter ½in. or more long and ripening under ground. B.M. 7598. G. 34:323.

L. H. B.

MORISÒNIA (Robert Morison, British botanist, 1628–1683). *Capparidàceæ.* Woody plants of very few species, in the West Indies and South America, one of which is listed abroad: a warmhouse subject, grown for its bloom.

Plants unarmed: lvs. simple, petioled, coriaceous: fls. in many-fld. axillary or terminal clusters, large or small; calyx tubular or campanulate, splitting; corolla of 4 obtuse petals; stamens 6–20, shorter or longer than the corolla, with subulate filaments; ovary 4-celled, stalked: fr. a globose berry. **M. americàna,** Linn. Low tree: lvs. oblong, at first with lepidote scales, shining, about 6 in. long: fls. white, petals and the infl. scurfy: berry 1½–2 in. diam. W. Indies, Colombia.

L. H. B.

MORMÒDES (Greek, *a grotesque creature*). *Orchidàceæ.* Rather large plants remarkable for the interesting form of their flowers, which suggested the name given to the genus by Lindley.

Pseudobulbs long, tapering, sheathed by the dry bases of the fallen lvs.: lvs. long, plaited, deciduous in the autumn: raceme from the base of the pseudobulbs, bearing many showy fls.; sepals and petals subequal, mostly narrow; labellum firmly united with the column, with revolute margins, rarely concave, turned to one side; column without appendages, twisted in the opposite direction from the labellum. Distinguished from the closely related genus Catasetum by its perfect fls. and wingless column.—About 20 species in Colombia, Cent. Amer. and Mex.

Mormodes are commonly found in poor condition among the collections, which is the result of neglect rather than difficulty of cultivation. They should be grown in small baskets suspended from the roof, in a compost of equal parts of clean chopped peat fiber, sphagnum and sod, interspersed by nodules of charcoal, and the whole pressed in firmly around the roots. The roots like to work among the charcoal, and this also serves the purpose of dividing the compost, thereby allowing it to dry out more readily. Mormodes do not require an abundance of water at any time, and the compost should be allowed to dry out frequently during the growing season. When at rest, an occasional application will suffice to keep the soil moist and the pseudobulbs from shriveling. Re-basketing should take place at the commencement of new growth in spring. They all require warmhouse temperature; the cattleya or cypripedium department affords them a proper location as to temperature and moisture. (Robert M. Grey.)

Colóssus, Reichb. f. Pseudobulbs 6–12 in. long, clothed with brown sheaths: lvs. elliptic-ovate, 10–15 in. long, plaited: raceme inclined, 2 ft. long, with the stalk; fls. 5–6 in. across; sepals and petals narrow-lanceolate, spreading or reflexed, with recurved margins, pink below, changing to yellow toward the upper portion; labellum ovate, long-acuminate, very revolute, yellow, somewhat sprinkled with pink dots. March. Cent. Amer. B.M. 5840.—A plant of striking appearance.

pardìna, Batem. Pseudobulbs 4–7 in. high, st.-like, sheathed by the bases of the lanceolate, striate lvs., which are 4 times as long: raceme nodding, many-fld., shorter than the lvs.; fls. yellow, spotted with reddish purple, fragrant, crowded on the upper end of the stalk; sepals and petals ovate, pointed, convergent; labellum nearly like the segms. but with 2 lateral acute lobes. July, Aug. Mex. B.M. 3900. F.C. 3:113.—A curious and rather rare plant. Var. **unícolor,** Hook. (*M. citrìna,* Hort.). Fls. of one color, all yellow. B.M. 3879. I.H. 1:25. G.C. III. 14:181. Var. **aurantìaca,** Rolfe. Sepals and petals golden yellow; labellum yellow. I.H. 39:144.

Buccinàtor, Lindl. Plants 1–2 ft. high: lvs. lanceolate, membranous, striate: fls. pale green, with an ivory-white lip; sepals linear-oblong, the lateral ones reflexed; petals erect; labellum subrotund-cuneate, with the sides rolled back, giving it the appearance of a trumpet. April. Mex. B.M. 4455 (*M. lentiginosa*). Var. **aurantiaca,** Rolfe. Differs in its golden fls. B.M. 8041. Var. **Rólfei,** Hort. Sepals and petals

2389. Morisia hypogæa. (×½)

bronzy green; labellum rosy crimson.—This plant is extremely variable in color, ranging from nearly white to chocolate-brown, the various forms being either spotted or plain. Its forms have been described under at least 7 distinct specific names.

luxàta, Lindl. Pseudobulbs 4–6 in. long: sheathing lvs. 1–2 ft. long, narrow-lanceolate, plaited: raceme much shorter; fls. 2 in. diam., rather fleshy and globular, lemon-yellow, with a dark brown streak down the labellum; sepals ovate-lanceolate; petals oblong, concave; labellum hemispherical, concave, obsoletely 3-lobed. July. Mex. B.R. 29:33. R.H. 1889:132.—Very fragrant. The fls. are remarkably distorted. Var. **ebúrnea,** Hort. Fls. creamy white. This is a very effective plant, superior to the type. G.C. II. 18:145. I.H. 34:35.

M. Oberlanderiànum, Lehm &. Kränzl. Sepals and petals lemon-color, rose-spotted; lip apricot, with large spots of same color. N. S. Amer. G.C. III. 28:318.—*M. revolùtum,* Rolfe. Fls. cinnabar, with a yellow lip; sepals and petals lanceolate, acute or acuminate; lip 3-lobed, the midlobe acuminate, reflexed. Peru. B.M. 8390.—*M. Wolteriànum,* Kränzl. Resembling M. Buccinator: racemes up to 10-fld.; fls. orange-brown. Peru.

Heinrich Hasselbring.
George V. Nash.†

MORMÓLYCE (a *bugbear* or *phantom,* probably referring to shape of flowers). *Orchidàceæ.* One Mexican epiphytic orchid, **M. ríngens,** Fenzl (*Trigonídium ríngens,* Lindl.), of the Maxillaria group: rhizome creeping: st. very short, with 1 coriaceous rather long lf. from a globose pseudobulb: scape leafless, slender, with 1 medium-sized yellowish green inodorous fl.; sepals spreading; labellum with erect lateral lobes and short middle lobe; column incurved; pollinia 4, ovoid.

MORNING-GLORY: *Ipomœa.*

MORRÈNIA (Professor Charles Morren, Belgian botanist). *Asclepiadàceæ.* Two pubescent twining shrubs of S. Amer., allied to Cynanchum, but differing in its convex 2-lobed stigma (flat or concave in Cynanchum) and the tubular corona, which is longer than the pistils, villose on the inside, and conniving over the pistils. A few other species have been added more recently. The lvs. are opposite and hastate. **M. odoràta,** Lindl., is more or less in cult., and is listed in S. Calif. It has white very fragrant fls. in dense cymes in the axils; sepals 5, linear; corolla rotate, the lobes wide-spreading and acuminate; corona tubular, 5-lobed. Argentina and Paraguay. Has merit for the agreeable vanilla fragrance of its inconspicuous fls. H.U. 5, p. 129. *M. brachystéphana,* Griseb., is a climber from Argentina with ovate, acuminate, hastate or cordate lvs., and loose axillary cymes of pure white star-shaped vanilla-scented fls.

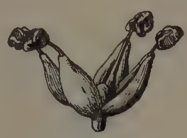
L. H. B.

2390. Staminate catkin of Russian mulberry. (Natural size)

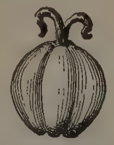
2391. Pistillate catkin of Russian mulberry. (Natural size)

MÒRUS (the ancient Latin name). *Moràceæ.* Mulberry. Ornamental and fruit-bearing small trees.

Unarmed, fls. diœcious or monœcious, both sexes in small hanging axillary catkins, the males soon falling (Figs. 2390, 2391); calyx 4-parted; stamens 4, the filaments partially inclosed in the calyx-lobes (Fig. 2392): pistillate fl. with one 2-celled ovary and 2 stigmas, and the 4 calyx-lobes adherent to the ovary (Fig. 2393) becoming fleshy and cohering into a long multiple fr. which suggests a blackberry in external appearance (Fig. 2394): real fr. an ovate compressed little achene, covered in the pulpy mass, 1 for every fertile fl. represented in the aggregate fr.—Temperate regions of the Old and New World. About 100 species of Morus have been described, but Bureau, DC. Prodr. 17:237 (1873) reduces them to 5; probably 10 or a dozen species represent the genus as now known. Two species are native in the U. S. Some of the names are now referred to other genera. Many of the names represent cultural forms of *M. alba.*



2392. Staminate flower of Russian mulberry. (Enlarged)



2393. Pistillate flower of Russian mulberry. (Enlarged)

Mulberries are grown as food for silkworms and for the edible fruits. The silkworm mulberry of history is *M. alba,* and the fruit-bearing mulberry of history is *M. nigra.* Yet, strangely enough, the leading fruit-bearing varieties of North America, are derived from *M. alba* (see Bailey, Bulletin No. 21, Cornell Experiment Station, and "Evolution of Our Native Fruits"). The native *M. rubra* has also given varieties which are grown for their fruits. The silkworm mulberry of the Chinese is *M. multicaulis,* by some considered to be a form of *M. alba.* This was introduced into North America early in last century, and for a time there was the wildest speculation in the selling and planting of the mulberry tree, and in the rearing of silkworms. These efforts have now largely passed away in North America. *M. multicaulis* gave rise to one variety which was prized for its fruits, the Downing. This variety is now little known, but the name has been popularly but erroneously transferred to a good variety of *M. alba* (the New American).

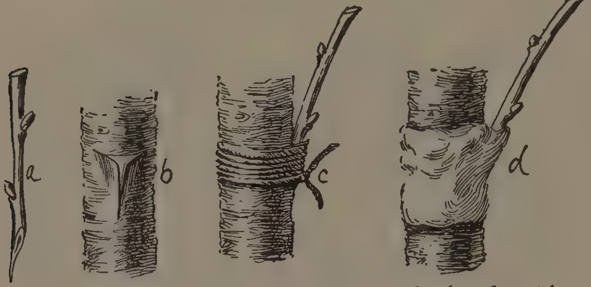
In North America the mulberry is known chiefly as a fruit-bearing tree, although it is never planted extensively and the fruit is scarcely known in the market. Two or three trees about the home grounds are sufficient to supply a family. The fruits are sweet and soft. To many persons they are too sweet. Because of their sweetness they are of little value for culinary uses. They usually drop when ripe. They are harvested by being shaken on sheets or straw. Birds are exceedingly fond of them. In the East and North, varieties of *M. alba* are chiefly grown, as the New American (frequently cultivated as Downing), Thorburn and Trowbridge. On the Pacific coast and in some parts of the South, varieties of *M. nigra* are grown, particularly the Black Persian. In parts of the South forms of the native *M. rubra* are grown, as Hicks and Stubbs. These are popular for planting in hog pastures, as the animals like the fruits. The mulberry thrives in any garden soil. It does well even on thin gravels and rocky slopes. For fruit-bearing purposes, trees may be planted from 20 to 40 feet apart.

The Russian mulberries are offshoots of *M. alba.* Their particular merits are great hardiness to withstand cold, drought and neglect. They are useful for low windbreaks and also for sheared hedges. They have become popular on the Plains. They are readily propagated by seeds, and the resulting plants are variable. Now and then a large-fruited form appears and it may be named and propagated, but for the most part the Russian mulberry

2394. Fruit of Morus alba. (Natural size)

has little merit for its fruits unless one desires to feed the birds.

Varieties of mulberries are now readily worked on seedlings of the Russian. One of the most successful grafts is S. D. Willard's method, shown in Fig. 2395.



2395. A method of grafting the mulberry. *a*, **the cion;** *b*, **matrix to receive cion;** *c*, **the graft tied;** *d*, **the graft waxed.**

The grafting is performed in spring when the bark will slip, using cions which have been kept perfectly dormant or on ice; *a* is the cion, the lower part being cut thin so that it will enter readily between the bark and wood of the stock; *b* is the stock, with an incision made through the bark essentially as for shield-budding; *c* shows the graft bound with cord or raffia; *d* shows the completed operation, the work being covered with wax. *Morus multicaulis* grows from cuttings in the South. These cuttings, with the buds removed to prevent sprouting, are often grafted before they are planted with a long cion of the desired variety (see Fig. 1691). The cutting acts as a nurse, and the cion takes root of itself if set deep enough.

There are many mulberries with ornamental forms. Of these, the most popular in America at present is Teas' weeping, a chance seedling of the Russian mulberry tribe. When grafted several feet high on straight Russian stock, it makes one of the best of small weeping lawn trees (Fig. 2396). It originated on the grounds of John C. Teas, Carthage, Missouri, about 1883. Various cut-leaved forms, mostly of *M. alba*, are seen in fine collections, of which the form known as *M. venosa* (Fig. 2397) is one of the best. The foliage of mulberries is interesting because so variable. Even on the same tree there may be leaves of several forms, while different trees of the same species may show strong individual traits. The most striking variations are in the lobing of the leaves.

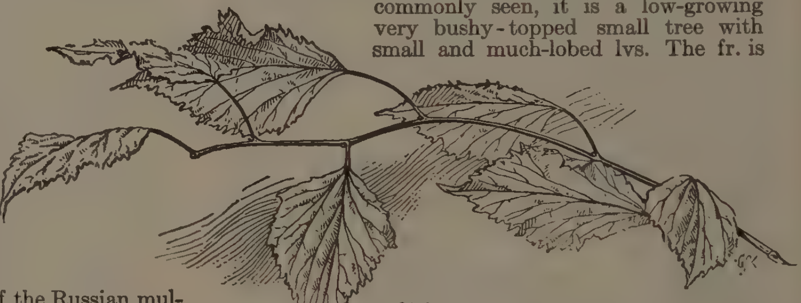
A. *Lvs. mostly bright and glabrous above, and usually glossy.*

B. *Style very short or practically none.*

2396. Teas' weeping mulberry.

álba, Linn. WHITE MULBERRY. Figs. 2398, 2399 B. Lvs. light green, rather small, smooth or very nearly so above and often shining, the veins prominent beneath and whitish, variously lobed or divided, the basal lobes unequal, the teeth large and for the most part rounded or nearly obtuse, the branches gray or grayish yellow: fr. variable, usually narrow, 1–2 in. long, white or violet, very sweet. China.—*Morus alba* has been cult. from the earliest times, chiefly for feeding the silk-worm. It is a frequent tree along roadsides and in the old yards in the eastern states, where the trunk sometimes attains a diam. of 2 ft. This half-wild form usually has rather small rounded shining lvs. with very large rounded teeth, and bears small whitish or violet frs. which are very sweet. Sometimes the frs. are an inch long, but they are oftener only half that length, and one sometimes finds trees on which the frs. are barely ¼in. long. Now and then a tree bears fr. nearly or quite black. Birds, poultry and hogs are fond of these mulberries. The trees are usually very thick-topped and bushy growers, but sometimes one is seen which, when young, has branches as straight and trim as a Northern Spy apple. These half-wild trees are seedlings, and this accounts for their variability. Var. **péndula,** Dipp. Branches slender, drooping. Var. **pyramidàlis,** Ser. (var *fastigiàta*, Schelle). Tree of pyramidal form: lvs. acute, usually lobed. Var. **laciniàta,** Beissn. (var. *skeletoniàna*, Schneid.) SKELETON-LEAVED MULBERRY. Lvs. regularly and deeply divided into narrow lobes, the terminal lobe and usually two of the lateral ones with very long points: a distinct and graceful form.

Var. **tatárica,** Loudon (*M. tatárica*, Linn.). RUSSIAN MULBERRY. Fig. 2400. A hardy type of *M. alba* which was intro. into our western states in 1875–77 by the Russian Mennonites. It differs little from the type of *M. alba* in botanical characters. As commonly seen, it is a low-growing very bushy-topped small tree with small and much-lobed lvs. The fr. is usually very small and insipid, and varies from creamy white to violet, and almost black.



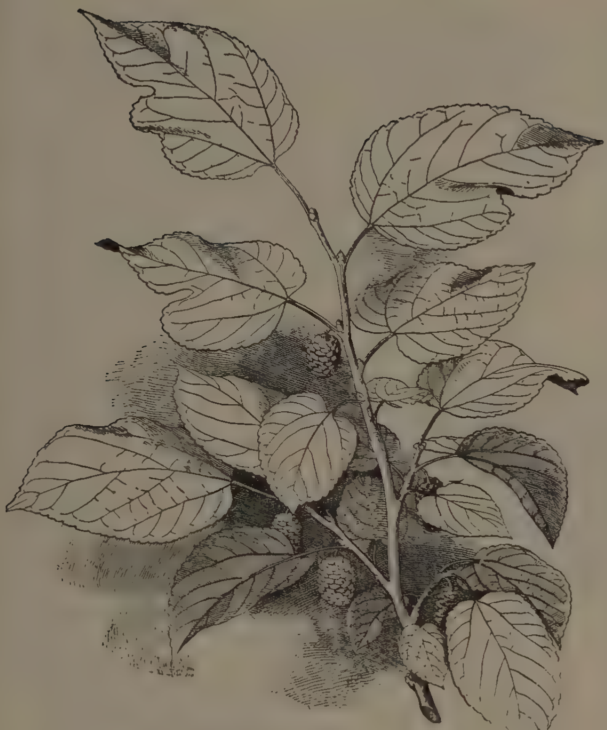
2397. The venosa mulberry.—Morus alba var. venosa.

Var. **venòsa,** Del. (var. *nervòsa*, Lodd. Var. *fibròsa*, Ser. *M. urticæfòlia*, Hort.). Fig. 2397. Lvs. contracted and jagged, and very strongly marked with many white veins. It bears fr. ½in. long. Among the horticultural curiosities this tree should find a place, although it is not grown by our nurserymen. Its ornamental value is considerable, especially when striking effects are desired. Rare in Amer. The history of this mulberry is obscure. Delile described it in a French report as long ago as 1826; of horticultural origin.

The variations of this species allow of many Latin names to be applied. The following names, which one may find in horticultural literature, are referable to *M. alba: byzantina, cedrona(?), colombassa, constantinopolitana, Fegyvernekiana, globosa, intermedia, italica, laciniata* (of some), *lucida, membranacea, macrophylla, Morettii, Morettiana, romana, rosea.*

BB. *Style evident or even prominent.*

japónica, Audib. (*M. álba* var. *stylòsa*, Bureau). Lvs. usually large, dull, rather thin, long-pointed, the rounded teeth very large and deep, or the margin even almost jagged, the lvs. upon the young growth usually deeply lobed. China, Korea, Japan.—This species has been intro. into this country, but apparently is not much known. It is tender in the N. when young. The fr. is described as short-oblong and red.



2398. Morus alba. (×¼)

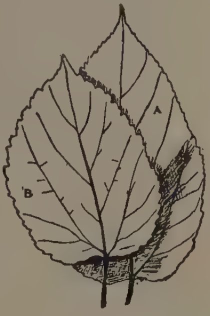
AA. *Lvs. dull green, mostly rough or pubescent.*

B. *Full-grown lvs. more than 4 in. long.*

multicaùlis, Perr. (*M. álba* var. *multicaùlis,* Loud. *M. álba* var. *latifòlia,* Bureau. *M. sinénsis,* Hort. *M. latifòlia,* Poir., which Bureau refers here, is probably *M. índica,* Linn.). Fig. 2399A. A strong-growing small tree or giant shrub, with dull roughish and very large long-pointed lvs., which are seldom or never prominently lobed, and which are often convex above, bearing black sweet fr.: style evident. China, where it is apparently the chief silkworm mulberry.—Once much grown in this country, but not now well known, particularly not in the N.

nìgra, Linn. Black Mulberry. Lvs. dark, dull green, rather large, tapering into a prominent point, commonly very rough above, usually not lobed, the base equal or very nearly so on both sides, the teeth rather small and close, the branches brown: fr. large, comparatively thick and fleshy, mostly dark-colored. The black mulberry is a native of Asia, probably of Persia and adjacent regions.—This is the species which is cult. in the Old World for its fr. In Amer. it is very little grown, although run wild now and then about grounds and along roadsides. It is not hardy, except in protected places, in New England and N. Y. The Black Persian mulberry of the S. and of Calif. is probably of this species.

rùbra, Linn. Native Red Mulberry. Fig. 2401. Lvs. usually large, very various, those on the young shoots deeply lobed with very oblique and rounded sinuses in the base of which there are no teeth, the upper surface rough and the lower one soft or variously pubescent, the teeth medium or comparatively small and either rounded or bluntish: fr. deep red, or when fully ripe almost black, variable in size, often very good, nearly always having an agreeable slight acidity. Mass. to Fla., Kans. and Texas, mostly in rich soils and bottom lands. S.S. 7:320.—This native mulberry has been tried for the feeding of silkworms, but with indifferent success. At least 3 of the named fr.-bearing mulberries belong to it, and a yellow-lvd. mulberry, which is somewhat grown for ornament, also appears to be of this species. The characteristic lobing of lvs. on the young growth is shown in the upper spray of Fig. 2401. The nearest approach to this lobing is in the Japanese (*Morus japonica*), and this affords another of those interesting parallelisms which exist between the Japanese and E. American floras. The red mulberry is the largest tree of the genus. In the S. it often attains a height of 70 ft. and a diam. of 3 or 4 ft. The timber is used for posts and light woodwork. Var. **tomentòsa,** Bureau (*M. tomentòsa,* Raf.). Lvs. very soft-pubescent and whitish beneath, often glossy but rough above. Texas.—A large-fruited form of this was intro. in 1889 by T. V. Munson as the Lampasas mulberry.



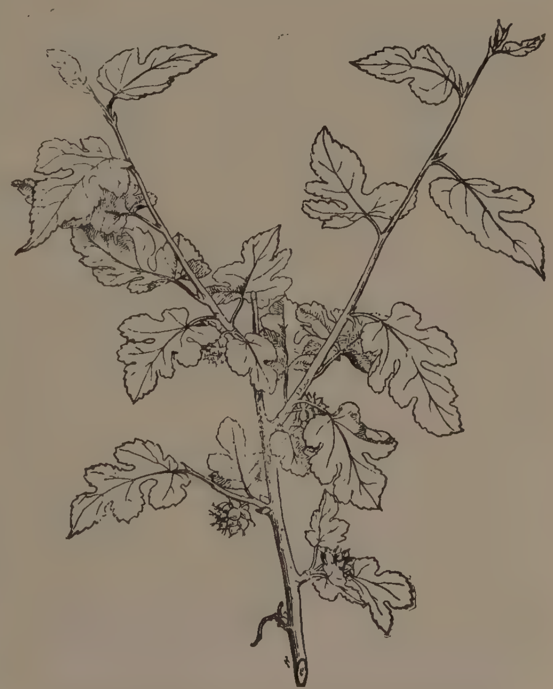
2399. Leaf of Morus alba at *B*; of M. multicaulis at *A*.

BB. *Full-grown lvs. usually 3 in. or less long.*

celtidifòlia, HBK. (*M. mexicàna,* Benth. *M. microphýlla,* Buckl.). Much smaller tree than *M. rubra,* rarely more than 25 ft. tall, and with smaller and smoother lvs. and smaller, sourer black fr., which ripens earlier and is not so good: lvs. cordate-ovate, more or less lobed, mucronate-serrate, nearly smooth on both sides: fr. short-ovate or sometimes nearly globular. Texas and Ariz. to Peru. S.S. 7:321.—Occasionally planted for its frs.

L. H. B.

MOSCHÓSMA (from the musk-like odor). *Labiàtæ.* In recent years there has come into prominence in European gardens a showy-flowered small shrub or tall herb from tropical and southern Africa under the name *Moschosma riparium,* but which N. E. Brown now refers to Iboza. The plants belonging to Iboza,



2400. Russian mulberry.—Morus alba var. tatarica. (×¼)

Brown writes, "have hitherto been referred to Moschosma, but they differ entirely from that genus in habit, calyx and corolla, and in having unisexual flowers, with the sexes on different plants. The small size and form of the corolla and the arrangement and spread of the stamens is somewhat like that of Mentha," next which he considers this genus should be placed.

Iboza (Kafir name of *I. riparia*) has more than a dozen species in S. and Trop. Afr.: fls. very small, diœcious, the males larger and bearing an abortive ovary or style; calyx minute, 3-lobed; corolla very small, with funnelform tube and more or less unequally 4–5-lobed limb; stamens in male fl. 4, free and separate; ovary 4-lobed: nutlets erect, oblong or ovoid, dorsally compressed.

2401. **Morus rubra, a native mulberry** (×⅓)
(See page 2071)

Ibòza ripària, N. E. Br., or **Moschósma ripàrium,** Hochst. Stout, 2–5 ft., perennial, the st. branching and obtusely 4-angled: lvs. broadly ovate, most of them notched at base and otherwise toothed: fls. very numerous, in erect panicles above the foliage and therefore conspicuous although small, creamy white with dark anthers. G.C. III. 31:122; 35:31. Gn. 61, p. 121; 65, p. 37; 69, p. 69. Gn.W. 20:90. G. 24:30.—An excellent bloomer under glass Dec.–Feb. After blooming, the plants may be cut back and good shoots secured for cuttings for the next winter's bloom. It is handled much like salvias and the species of coleus.

L. H. B.

MOSS. A general name for many humble green plants of the cryptogamia (so-called flowerless plants), mostly with distinct stems and foliage leaves. In North America there are about 1,000 species, distributed in various families. They have solitary, or rarely clustered, mostly stalked spore-cases or capsules arising from the apex or side of a leafy stem (Fig. 2402). The capsule is covered with a thin cap or calyptra (*c*) which is shed at maturity. The capsule opens by means of a lid or operculum (*o*), and the orifice is usually guarded by one or two rows of teeth, or peristome. A fuller discussion of the structure and relationships of the mosses will be found in Volume I, on page 6. The mosses are not horticultural plants. Sphagnum moss is much used as a packing material and for holding moisture about pots, and as a medium in which to sow delicate seeds, but it is collected from bogs and not grown for the purpose. Club-mosses are not true mosses but lycopodiums (see *Lycopodium* and *Selaginella*). The "moss" on fruit and other trees is mostly lichen. The Florida or Spanish moss is a flowering plant (see *Tillandsia*).

MOSS PINK: *Phlox subulata.*

MOULDS, MOLD. The term mould is applied to any small fungous growth which appears on decaying organic matter, such as fruits, both fresh and preserved, vegetables, and so on. The moulds are very simple fungi producing immense numbers of spores, a fact which accounts for their presence everywhere, in the air, in dust, and on all exposed bodies. As a rule, these fungi are not directly injurious to plants; they are normally saprophytes and perform a great service in disorganizing organic matter which would otherwise accumulate on the earth. A few of the species may become parasitic. Thus, species of Botrytis often attack lettuce in forcing-houses which are too close and damp. Carnation buds and violet plants are also frequently injured by Botrytis. The mould-like growths occurring on boards in damp cellars or in greenhouse benches are sterile mycelia of higher fungi. These do not attack plants, but sometimes, as in the case of violets, grow over and smother the plants. The so-called sooty moulds constitute the small family of the Perisporiaceæ. They receive their name from the fact that they form dark olive-green or black coatings on the twigs and leaves of plants on which they grow. They are not parasitic but live for the most part on the honey-dew secreted by insects and sometimes on the insects themselves. Apparently little direct damage is caused to plants by these fungi. It has been found in laboratory experiments with isolated leaves that those freed from the fungous coating absorb more carbon-dioxide and liberate more oxygen than leaves coated with the fungus. The extent of injury arising from interference with physiological processes on account of shading and the possible closing of the stomata under natural conditions has not been generally determined, but it is certain that orange and lemon trees sometimes suffer serious injury, in fruit and foliage, brought about in this way. The sooty moulds are mostly confined to tropical and subtropical regions where they are abundant on many kinds of plants. They occur occasionally in greenhouses on coriaceous-leaved coolhouse plants, such as oleander and evonymus, which were formerly more generally grown. With the advent of present-day heating systems and the introduction of the practice of growing rapidly shifting crops, these fungi, never of great significance, have practically disappeared from greenhouses. The following are among the more common forms of sooty moulds: *Dimerosporium mangifera*, on mango; *D. pulchrum*, on privet, lonicera and cornus; *Apiosporium salicinum*, common on leaves of woody plants; *A. Footii*, on greenhouse plants; *Capnodium fœdum*, on oleander; *C. guajavæ* on guava and other tropical shrubs and trees; *Meliola Penzigii* causes considerable injury to citrus trees in Florida by coating the leaves and fruit. The numerous forms occurring in the tropics have not been fully investigated. See, also, *Diseases* and *Fungi*.

Heinrich Hasselbring.

MOUNTAIN-ASH: *Sorbus Aucuparia.* **M.-Ebony:** *Bauhinia.* **M.-Laurel:** *Kalmia*, particularly *K. latifolia.* **M.-Mahoe:** *Hibiscus elatus.* **M.-Mahogany:** *Cercocarpus.* **M.-Mint:** *Pycnanthemum.* **M.-Rose:** *Antigonon.*

MOURNING BRIDE: *Scabiosa.*

MOVING PLANT: *Desmodium gyrans.*

MUCKLAND-GARDENING. In recent years there has been a large development of truck-gardening in swamps, bogs and similar areas that have been drained and improved. These areas have deep black soil, very adaptable to onions, lettuce, celery and certain other crops, and special methods have been developed on them, so much so that muckland-gardening has become almost a special department of horticultural operations.

Location.

One should be careful in selecting muck, as poor muck will not yield paying crops. A patch of muck that can be drained so that the water-table will be 2½ feet from the surface, is most desirable. It should be so located that a running stream of water will flow through or near the muck, which will keep it moist during a dry spell. Never buy any new muckland for gardening purposes if it is not covered with a good crop of timber or weeds. Muck covered with a thrifty growth of elm, black ash, and soft maple, will give good crops when brought under cultivation. Cedar and spruce muck are not so good for all kinds of muckland crops. If a muck tract has been cleared from timber and is not cultivated, it should grow a very thrifty crop of swamp weeds; if it does not show a good growth of weeds it should be avoided.

Endeavor to locate near a railroad or on a good improved highway. Good mucklands yield large and bulky crops and the cost of long hauls to market or the railroad will be very high. In a few years the extra expense of drawing the crops to market will exceed the first cost of the muck itself. It is also advantageous to locate where one can ship on several good railroads. It will give a wider range of markets and a lower freight rate.

It is well to have the muck-garden near a large body of water. Muckland so located has a much longer growing season. The water warms the air during the cold nights in the fall, and many times saves the entire crop from a frost. It also cools the very hot air during the midsummer.

Clearing and preparing for cropping.

If the muckland is covered with a heavy growth of timber, it should be cut down and the stumps removed. There are many ways of clearing and removing the stumps, either dynamite or stump-pullers working very well. The holes should be filled up before plowing, and all the roots that the plow comes in contact with removed. A good disc-plow does better work on newly cleared land, as the small roots will not clog a disc as they do a moldboard plow. Corn is a good crop to which to plant new muckland, as it will grow well and helps greatly to subdue the land. The following year the land may be planted to garden crops providing it has been well cultivated while the corn was growing, and carefully prepared and fitted to receive the muck crops.

2402. Hair-cap moss.—Polytrichum commune.

Drainage.

All mucklands must have good drainage or they will not yield paying crops. The water-table should be 2½ feet from the surface to give best results. In order that the water may be lowered to the same level throughout the tract, it will be necessary to construct main and lateral ditches. The latter should be placed from 5 to 10 rods apart, according to the condition of the muck. If the muck is coarse and fibrous, the lateral ditches may be placed farther apart; if it has reached a more advanced stage of decay so that it is fine and pulverized, the lateral ditches must be placed closer together. If the natural fall in the main ditch is not sufficient to give ample drainage and the water-shed from the uplands is not too great, artificial drainage can be installed and will prove very profitable. The water should be led to the lowest point in the main ditch and a pumping-station installed, with which the water is elevated. When artificial drainage is used, the land should be surrounded by a good dyke and should have a ditch all around the muck on the inside of the dyke leading to the pumping-station. There are many muck-gardens operated by this system of drainage that are producing good crops. They are not affected by a drought as are the higher located muck-gardens. The expense for power is not very high, if one has a good outfit for pumping.

Fertilizers.

All mucklands in the northern states are very rich in organic matter, fairly well supplied with phosphoric acid and low in potash, and very high in nitrogen. Samples of muck taken from various sections show by analysis that they contain materials as follows:

Organic matter	from	82.5	to	88.7	per cent.
Nitrogen	from	1.8	to	2.42	per cent.
Phosphoric acid	from	.27	to	1.9	per cent.
Potash	from	.15	to	.26	per cent.
Calcium-oxide	from	4.2	to	6.3	per cent.

However, the plant-food found in muck is not available to garden crops in large enough quantities to warrant the growing of such crops without the use of commercial fertilizer or stable-manures. When muckland is brought under cultivation, it renders some of the plant-food available to the crops, but it would mean failure to any grower if he did not use fertilizer of some kind each year. A brand of fertilizer containing about 2 per cent nitrogen, 8 per cent available phosphoric acid and 10 per cent potash, is a good mixture with which to start the crop. If the growth is not fast enough after the crop is well started, apply nitrate of soda. By watching the growth of the crop, one will soon learn what to apply.

Many growers apply about 1,000 pounds of 2:8:10 fertilizer to the acre in the spring just before the crop is planted and work it well into the soil and then apply from 400 to 1,000 pounds during the growing season. Some growers prefer to apply all the phosphoric acid and potash in the spring and then feed the crop on nitrogen alone during the growing season, using nitrate of soda, dried blood and tankage. Not more than 400 pounds of nitrate of soda to the acre is used at one time, unless the ground is very cold and wet in early spring. Such crops as onions, lettuce, carrots and beets do not need such large amounts. Spinach will respond greatly to a liberal application of nitrate of soda. One grower has raised sixteen tons of spinach to the acre and harvested the crop by June 8 by applying 800 pounds of 2:8:10 to the acre before sowing the seed and 600 pounds of nitrate of soda to the acre when the crop was well started. Twenty-five carloads of celery were also grown on 8 acres by using 3,000 pounds of commercial fertilizer, 4:7:10 brand, before planting, and side-dressing with fish tankage every two weeks, making three applications during the season after the crop had started and using 1,200 pounds of tankage to the acre in the three applications. However, this celery was grown under irrigation. It is not advisable for anyone to use that amount of fertilizer unless he thoroughly understands the health condition of the celery crop, as he may spoil the entire crop by so doing. Such crops as onion and celery should produce a good yield by applying from 1,000 to 2,000 pounds of 2:8:10 to the acre during the season. Lettuce, carrots, beets and potatoes should do well on 600 to 1,000 pounds to the acre. Spinach will do well on 500 pounds of 2:8:10

and 500 pounds of nitrate of soda to the acre. Never sow spinach on a new muck, as it will not do well.

Vegetable crops adapted to muckland.

The main crops grown on muckland in the northeastern states are onions, celery, and lettuce, but there are many other crops that yield good returns to the grower. Potatoes grown on muckland are, as a rule, not very good for eating purposes but they make the choicest kind of seed stock. A good business could be worked up on muckland-grown seed potatoes.

Sweet corn grows very well on muck and the yield is large, but it must be grown for canning purposes as the season is not long enough fully to mature the crop. Peas for canning purposes do well. Beets for winter use or for canning while small yield large crops. Carrots yield enormous crops of excellent quality. Parsnips do well on well-drained muck but not unless the water-table is low. Horse-radish grows to perfection and the quality is good. Spinach grows better on old muck than on any other kind of soil, and the quality is far superior to upland spinach, as it is entirely free from grit. Asparagus grows to perfection on well-drained muck but the water-level must be kept down below the crowns during the winter months or it will rot them. Cauliflower grows well on muckland. Cabbage does very well on shallow muck, but is likely to head soft on deep muck. Asters and sweet peas for cut-flowers grow to perfection on muck, and there is a good demand for the blossoms in the large cities. Gladioli grown for bulbs do very well on muck.

Tillage and handling of muckland.

There are many different opinions as to how muck should be tilled. Some growers believe in deep plowing so as to get the best of conditions possible for a good root-growth. However, deep plowing should never be practised in the spring. If virgin muck soil is brought to the surface in spring or summer, it will bake and form lumps much like soft coal, and will not hold the moisture and therefore the crops will not do well. The deep plowing should be done in the fall after the frost has worked on the virgin subsoil which when brought to the top becomes pulverized and will be in fine condition for cropping the next spring. When the frost is out of the ground in the spring, break the soil up thoroughly with a cultivator to a depth of 6 inches, and put on the first application of fertilizer. Work this well into the soil by dragging it three or four times and then go over the land with a leveler, after which the seed is sown.

Deep cultivation in the early spring helps to dry out the soil and warms it up, and causes the roots of the crop to work deeply into the ground. As the crops grow and the weather and soil warm up, cultivation must be continued, but of less depth so that the roots are not cut off. If shallow cultivation is practised at first, the root-growth will all be near the surface and when dry weather sets in, roots will have no moisture and the plants stop growing until they can send roots down into the moist soil. A mulch of dry muck for a depth of 1 or 2 inches will carry the crop through a dry spell in good condition. In wet weather the land should be left in ridges after cultivating, as this helps to dry it. In dry weather, however, it should be left as level as possible in order to hold the moisture.

HENRY GREFFRATH.

MUCÙNA (Brazilian name). *Leguminòsæ.* Under this name several annual bean-like vines have been grown in the southern states for forage, green-manuring and ornament. The genus, as accepted by the standard works, has recently been divided, however, and the plants cultivated in this country are separated under Stizolobium (which see).

Mucuna, as thus re-defined (Bort, Bull. No. 141 Bur. Pl. Ind., U.S. Dept. Agric., and Piper & Tracy, Bull. No. 179, same), is a genus of perennials, whereas Stizolobium is annual or essentially so; in Mucuna, the hilum on the seed is much elongated and band-like, extending nearly all the way around the seed; in Stizolobium, the hilum is linear, elevated and oblong-crateriform, extending from one-fifth to nearly one-fourth of the circumference of the seed; there are also marked differences in germination. As thus restricted, Mucuna appears to have no species cult. in this country. L. H. B.

MUEHLENBÉCKIA (after Dr. Muehlenbeck, a Swiss physician). *Polygonàceæ.* A rather small group of climbing or erect, usually slightly shrubby plants, all inhabitants of the South Temperate Zone.

Leaves alternate, with sheathing stipules at the base: fls. unisexual, small, fascicled in the lf.-axils; perianth with 5 nearly equal lobes; stamens 8; ovary 1-celled, 1-ovuled; styles 3: achene obtuse or acute, 3-angled, crustaceous, about equaling the succulent perianth. Ornamental plants, various in appearance. Species about 15.

A. *Stigma fringed.*

B. *Sts. very flat and broad.*

platyclàda, Meissn. (*Coccóloba platyclàda,* F. Muell.). A very interesting, erect, shrubby plant with broad, flat, ribbon-like, glossy, delicately striate branches replacing the lvs., which are scanty or entirely wanting: lvs. membranous, oblong-lanceolate, sometimes hastate: bracts and stipules very short: fls. white, in few-fld. clusters: achenes included in the fleshy perianth, which at maturity is bright red or at length deep purple and quite showy. Solomon Isls. B.M. 5382.—Frequently grown in greenhouses because of the odd flat sts. and showy fr.

BB. *Sts. slender and nearly terete: lvs. fiddle-shaped.*

vàrians, Meissn. Somewhat shrubby at base: sts. smooth, herbaceous, filiform, twining; internodes elongated: sheaths white, narrow, 3 lines long: lvs. 1 in. or less long, petioled, ovate, acuminate, deeply lobed at the middle on each side, fiddle-shaped; sinus broad or narrow-obtuse; otherwise entire: racemes axillary, solitary or in 2's, simple or bifid, forming a terminal leafy panicle 3–4 in. long; fls. subsessile, similar to those of *Polygonum aviculare.* Habitat (?).

AA. *Stigma papillose.*

B. *Sts. low, rarely twining: lvs. 3–5 lines long.*

compléxa, Meissn. WIRE PLANT. A twining or drooping, somewhat shrubby plant: st. slender and much-branched, glabrous except when very young: lvs. very small, 3–5 lines long, light green, about equaling the petiole, mostly fiddle-shaped, rarely hastate; sheaths small, tubular, deciduous: fls. 1–6, in somewhat racemose, pubescent clusters, green and inconspicuous: fr. with a succulent, transparent, whitish, persistent perianth. New Zeal. B.M. 8449.—A graceful basket plant. Fr.-clusters glistening, showy. It is sometimes called Polygonum by florists. A popular high-climbing vine in Calif., on chimneys and elsewhere. Of variable habit.

BB. *Sts. coarser, twining, reddish: lvs. larger.*

chilénsis, Meissn. Somewhat shrubby, glabrous: branches strongly sulcate, loosely twining, angular, "bright red:" lvs. somewhat fleshy or coriaceous, petioled, triangular or hastate-cordate, ovate, oblong or lanceolate, truncate or attenuate at base, 1-nerved; margin entire, somewhat revolute, smooth: racemes axillary and terminal, solitary, simple, lax and leafless, rarely contracted; bracts about equaling the pedicels: achenes subglobose, 3-angled. Chile and Peru.

M. adpréssa, Meissn. Large, diffuse, bushy plant, with small pink fls. in paniculate spikes: lvs. up to 2 in. long, broadly oblong, often cordate, glabrous. Austral. B.M. 3145 (as Polygonum).—Cult. in Eu.—*M. nàna,* Hort., is said to be a dwarf form. The botanical status is uncertain.

K. M. WIEGAND.

MUHLENBÉRGIA (Dr. H. Muhlenberg, who wrote a work upon American grasses in 1817). Sometimes spelled *Muehlenbergia*. *Gramineæ*. Spikelets 1-fld.; lemma firm, mucronate or awned. About 60 species, mostly American. **M. racemòsa**, BSP. (*M. glomeràta*, Trin.). An erect perennial, with rather short appressed lvs.: panicle contracted and spike-like; glumes nearly equal, 1-nerved, extending into short awns; lemma longer than empty glumes, excluding the awns. Dept. Agric., Div. Agrost. 7:109. Wet ground, nearly throughout N. U. S.

A. S. HITCHCOCK.

MUÍLLA (an inversion of Allium). *Liliàceæ*. Bulbous plants closely allied to Allium.

Perianth subrotate, persistent, of 6 nearly equal slightly united segms., spreading, closely 2- to 3-nerved; stamens in one row at the base; anthers versatile; filaments slightly thicker at the base; ovules 8–10 in a cell; style club-shaped, persistent and at length splitting: caps. obovate or subglobose, sessile or nearly so: fls. greenish white: pedicels not jointed: lvs. several.—One species from Calif., W. Nev. An unimportant plant advertised by specialists in Pacific coast bulbs. It has a slender scape 3–12 in. high, bearing early in the year an umbel of 5–15 greenish white fls., each about ½in. across. Differs from Allium, in that instead of a true bulb it has a fibrous-coated corm, and also lacks the onion-like odor.

marítima, Wats. Lvs. several, not sheathing at base, scabrous, as long as the scape: corm small: caps. ¼in. long, with usually 3 seeds in each cell. Calif., W. Nev. —Saline regions.

A. C. HOTTES.†

MÙKIA: *Melothria*.

MULBERRY: *Morus*. **French M.**: *Callicarpa americana*. **Indian M.**: *Morinda*. **Paper M.**: *Broussonetia*. The wild *Rubus odoratus* is improperly called mulberry in some parts of the country.

MULCHING is the covering of the soil or earth with some protecting material. It has six or more general objects: (1) to conserve moisture by preventing or hindering evaporation; (2) to protect plants from winter injury; (3) to keep the surface of the soil loose and friable; (4) to add plant-food to the soil; (5) to protect berries or flowers from dirt spattered up by rain, as in the case of strawberries; (6) to keep down weeds.

The moisture available to agricultural plants is held in the soil by means of capillary or film attraction. The soil may be conceived to be full of irregular capillary tubes or connecting interstices which have a general vertical direction. The upper ends of these spaces are in contact with the atmosphere, and they are constantly giving off moisture into the air. If the upper openings of these interstices are covered, as with a board or a mulch, the evaporation into the atmosphere is relatively slight. If they are covered with a mulch of ashes or sawdust, a similar result may be attained. A dry earth-mulch may be made on the spot by tilling the upper 2 or 3 inches of soil. The philosophy of summer tillage is to prepare and to maintain this mulch of soil, thereby interposing a relatively non-capillary stratum between the moist soil and the air. This earth-mulch may itself be dust-dry, but it protects the soil beneath. There is more or less evaporation into the interstices of the earth-mulch itself, and some of the moisture ascends through the mulch and escapes into the atmosphere; but it has been found by long experience and by experiments that the earth-mulch greatly lessens evaporation. The frequent stirring of the surface soil in summer is said to make the land moist; as a matter of fact, it keeps it moist. When it is impracticable to keep a surface mulch by means of tillage with horse tools or a rake, it is sometimes advisable to use straw or manure. Mulching newly set trees is often desirable when it is not possible to till the land or not practicable to water them. The ideal mulch to conserve moisture, however, is the loose layer of earth, since the stirring of the soil not only provides the mulch but also sets at work various chemical and biological forces that make the plant-food more available.

All herbaceous plants and most shrubs are benefited by a mulch in the fall, no matter how hardy they may be in the given locality. Nature's mulch is the debris of fallen leaves, grass and other litter. The autumn leaves that blow into the borders and the clumps of shrubbery, afford the very best winter mulch; and yet it is a common practice scrupulously to collect and burn these leaves in the fall, and then if the plants are mulched to apply manure. This is doubtful wisdom. The herbaceous border will be benefited by a loose open mulch, 4 to 6 inches deep. If the mulch is of such character as to become very hard and dense, and to hold too much water, it may be injurious. Leaf-mold, loose muck or peat, autumn leaves mixed with some litter that will prevent them from packing too hard, manure which is not too strong in nitrogen and potash, fine straw, sawdust, shavings, pine-needles, evergreen boughs—these are some of the materials that may be used as a mulch to good advantage. If the mulch has thoroughly decayed by spring, it may be left on the land and it will make a fine loamy covering that will be much like the vegetable-mold found in the woods. Too often the passion for cleanness sacrifices the welfare of the border. Persons will collect and burn every stray autumn leaf, but will not notice many kinds of dirt which are really objectionable. The mulch keeps the surface of the soil loose and mellow because it protects it from the beating of heavy rains and the weight of snow. The vegetable-fiber that works into the surface also prevents the particles of heavy clay soils from running together or puddling. Soils that are covered with a mulch do not bake.

Fall-set herbaceous plants, as pansies, should be covered with 2 or 3 inches of straw or other material to protect them from "heaving" and from the direct injury of alternating conditions.

Whenever the mulch contains soluble plant-food, the soil receives the leachings and is enriched. Stable-manure is an ideal mulch for enriching the soil, but if the manure is fresh and strong, it is likely to injure the crowns of some plants.

L. H. B.

MULGÈDIUM (name alludes to the milky juice). *Compósitæ*. A group by most authors united with Lactuca, but differing in the blue to white rays, and the oblong mostly beaked achene. It is also closely allied to Sonchus. Some species are offered as outdoor garden herbs; annual, biennial and perennial. Plants of easy culture. The following species might properly be included in the account of Lactuca, although the nomenclature of some of the garden forms is open to doubt.

alpìnum, Less. (*Lactùca alpìna*, Benth. & Hook.). Perennial, 3 ft., erect: lvs. alternate, the radical lyrate-dentate and petioled, the terminal lobe large: fls. deep blue, like those of wild chicory, numerous, in a corymbose cluster; involucre of unequal scales in several series, hairy. Eu., in mountains and far N., prized for its abundant foliage and attractive fls.; requires a moist somewhat shaded place.

thianschánicum, Regel & Schmalh. Glabrous, robust, 3–5 ft. tall: lvs. sharply dentate or the upper ciliate-dentate; the lower lyrate with the terminal lobe very large, lateral lobes confluent with the broadly winged petiole, cordate and clasping at the base: raceme much elongated, simple, or branched at the base only; heads oblong, many-fld.; involucre glabrous; fls. blue, twice as long as the involucre: achenes linear-oblong, multistriate, narrowed toward the apex; pappus hairy, deciduous. Cent. Asia.

macrophýllum, DC. Perennial: st. strict, hispid at top: lvs. ample, sublyrate, cordate at base, hairy beneath, the terminal lobe large and cordate: panicle lax, hispid, with blue-rayed heads of size of chicory; involucre sparsely hispid.—Said by the older botanists to come from N. Amer., but probably European.

M. Bourgæ̀i, Boiss.=Lactuca Bourgæi, described on p. 1766.—*M. gigantèum*, Hort. (Lactuca gigantea, Hort.) Perennial, 6–8 ft.: fls. blue-violet, paniculate. Probably of garden origin, or a form of some robust species.—*M. Plumièri*, DC. (Lactuca Plumieri, Gren. & Godr.). Perennial, glabrous: st. erect: lvs. runcinate-pinnatifid, somewhat glaucous beneath: panicle sub-corymbose, bearing rather large blue-rayed heads. Mountains of Cent. and S. Eu.

L. H. B.

MULLEIN: *Verbascum.* **M. Pink:** *Lychnis Coronaria.*

MURRÆ̀A or MURRÀYA (one of the *Rutaceæ*, named for J. A. Murray, 1740–1791, professor in Göttingen) is now referred to Chalcas (Volume II, page 729). There is only one of the species in general cultivation, the orange jessamine, *Chalcas exotica* (or *M. exotica*), from India, China, Australia and the Pacific islands. P. J. Berckmans writes (A. F. 11:1367, with picture) that it "needs ample pot room and a liberal supply of plant-food. An annual application of bone-meal when repotting in February intensifies the color of the foliage, increases the size of the flowers, and causes it to bloom more frequently. When properly treated, the first crop of flowers usually appears here [Georgia] during May, another during July, and this is succeeded at intervals of from four to six weeks until fall. For winter, give it the temperature of a cool greenhouse, but during summer it thrives best when given full sunshine outdoors." The other species of Chalcas, of which there are perhaps a half-dozen in the Indo-Malay region, are probably not in cultivation in this country. *Chálcas paniculàta*, Linn. (*M. paniculàta*, Jack), is probably a form of *C. exotica*. It is the satinwood or cosmetic bark tree. Arboreous: corymbs few-fld. or fls. solitary.—The wood of this species is considerably used because of its strength and endurance and light yellow color. The bark is used as a cosmetic.

C. Kœ̀nigii, Kurz. (M. Kœnigii, Spreng.). Lvs. 10–20-foliolate, pubescent or rarely glabrous. Along the foot of the Himalayas in India.—A small, strong-smelling tree. The bark, lvs. and roots of this species are used in India as a tonic. Other little-known species occur in India and Indo-China.

Walter T. Swingle.†

MÙSA (named after Antonio Musa, physician to Octavius Augustus, first emperor of Rome, 63–14 B. C.). *Musàceæ.* The largest of tree-like herbs, grown for the ornament of their large striking foliage, for fruit, and for fiber.

Bulbous or with perennial rootstocks: lvs. usually gigantic, entire, oblong or elliptic, pinnately parallel-veined, arranged in a loose rosette, sometimes dark above and glaucous beneath, with a narrow red edge, usually bright green on both sides; in the young state with narrow hyaline margins beautifully crimsoned or white; midrib with a deep rounded groove above; sheathing petioles long or short, forming a false st.-like structure: fls. unisexual, in half-whorl-like clusters in a terminal spike (Fig. 462, Vol. I), each cluster subtended by a large spathe-like, colored bract, and all borne on a long or short often velvety or puberulent rachis emerging from the center of the leafy envelopes at the top of the false st.; lower clusters female, upper male (actually hermaphrodite female and hermaphrodite male, the opposing parts being dwarfed, functionless or sometimes absent); perianth consisting of a calyx at first tubular but soon splitting down one side with a 3–5-toothed apex and opposite the calyx a single simple or 3-toothed petal; stamens normally 6, 5 with 2-celled vasifixed anthers, the sixth usually suppressed; ovary inferior, 3-celled, cells with many superposed ovules: fr. a large berry, short or elongated, pulpy or dry, angular, oblong or cylindrical; seeds when produced are ⅛–⅝in. diam., subglobose or angled by pressure. testa hard, indented at the base and apex, albumen mealy, embryo subtruncate.—Sixty-seven species and over 200 cult. varieties are known, native of Trop. Asia, Afr., Austral. and adjacent islands. The fruit of the banana is of great importance in the tropics for food. It is imported in large quantities into the U. S. from W. Indies and Cent. Amer. and grown in the Gulf States (see *Banana*). Several ornamental species are grown extensively in the N. and are hardy from 38° north to 35° south latitude. Latest publications: Baker, Species and Principal Varieties of Musa, K.B. 229–314 (1894). Schumann, Das Pflanzenreich 45:13–28 (1900). Fawcett, The Banana, Its Cultivation, Distribution and Commercial Uses, 1913. Popenoe, Origin of the Banana, Journal of Heredity 5:273–280 (1914).

When plants of a most gorgeous tropical effect are wanted, they will always be found among the musas. To grow these plants to perfection, a large greenhouse will be required. The musas can be increased from suckers, which are found around old plants, and which can readily be separated from the parent plant with a piece of root. These suckers may be potted up into 4-, 5- or 6-inch pots, using a compost of fibrous loam three parts, well-decayed cow-manure one part, enough sand to keep it open and porous, and a good dash of bone-meal. Pot each sucker firmly. These young plants should be placed in a very close and humid atmosphere so as to encourage quick growth. They prefer a night temperature of not less than 68° with about 10° to 20° more during the day. These young plants may be started anywhere from the middle of February up to the first of April. When they have filled their pots with roots, they can be shifted into pots two sizes larger. These shifts can be kept up until they are in tubs 2 feet square. As the shifts become larger make the compost richer, as they are rank feeders. When musas are grown for decorative purposes, it will be found convenient to have them in tubs as they are more easily moved. When they are wanted to show the production of fine fruit, they should be planted out in the middle of a roomy house where the night temperature does not fall below 65°. During the spring and summer months, let the temperature increase in proportion to the outside conditions, as musas delight in a high temperature. They will stand much feeding and should be given liquid manure once or twice a week during the spring and summer months. By giving care to watering, syringing and ventilation, they will grow rapidly. While musas like plenty of sunshine, they are some-

2403. Musa Ensete.

times better for a slight shading during the middle of the day, but only enough to prevent scorching of the foliage. During the winter the night temperature may be lowered to 60°. They will also require less water and syringing. The musas used for subtropical beds and gardens are grown from seed, such as *M. Ensete*, *M. Basjoo*, *M. superba*, and the like. These seeds may be planted in pans or flats in a compost of loam, leaf-mold and sand in equal parts. The seeds should be covered about four times their size in depth and pressed firmly. These pans should be placed where they can have plenty of bottom-heat. When the seedlings appear, pot them off and grow on the same as above. These plants can be lifted in the fall and the soil shaken off and placed in some house or cellar where the temperature does not go below 45°. (J. J. M. Farrell.)

A. *Sts. short, bottle-shaped: male fls. many to a bract, free petal usually 3-toothed: fr. not edible: usually not stoloniferous. (Subgenus Physocaulis.)*

B. *Free petal entire: seeds few, large (about 1 in. diam.).*

1. **ventricòsa,** Welw. (*M. africàna*, Bull, young form). Whole plant 8–10 ft. high, not stoloniferous: sts. much swollen, 4 ft. diam. at base: lvs. oblanceolate-oblong, 4–5 ft. long, thick in texture, bright green; midrib pale red: spike drooping; calyx entire; free petal entire, ⅓in. long: fr. coriaceous, dry, 2–3 in. long; seeds about 1 in. diam., angled by pressure. Angola, in rocky places near rivulets.—Cult. in S. Calif. Tender but more ornamental than *M. Ensete*.

BB. *Free petal 3-toothed or lobed.*

C. *Seeds few, large (about ¾–1 in. diam.).*

D. *The seeds smooth.*

2. **Ensète,** Gmel. (*M. abyssinica*, Hort. *Ensète edùle*, Horan.). ABYSSINIAN BANANA. Fig. 2403. Whole plant 30–40 ft. high, not stoloniferous: st. 13–20 ft. high, swollen at the base: lvs. oblong, acute, often 20 ft. long by 3 ft. wide; midrib red: bracts densely imbricated, 9–12 in. long, dark claret-brown: spike erect; fls. whitish, 1½–2 in. long, often 20 or more in a cluster; calyx 3-lobed; free petal short, 3-lobed: fr. coriaceous, dry, 2–3 in. long; seeds 1–4, black, glossy, nearly 1 in. diam., with a prominent raised border around the hilum. Mountains of Abyssinia. B.M. 5223, 5224. R.H. 1861, p. 124, note; 1888, p. 32. G.C. II. 15:435; 21:19; III 16:697. Gn. 47, p. 5; 48, p. 406. V. 5:53. F.E. 11:470. G.M. 52:655; 54:375.—The largest known, as well as one of the oldest (being represented in ancient Egyptian sculptures), and most widely cult. of all decorative bananas. Cult. in S. Calif. and Fla. Prop. entirely from seed in hotbeds. Yields a good fiber.

DD. *The seeds longitudinally ribbed.*

3. **Hòlstii,** K. Schum. Whole plant 15–20 ft. high: lvs. 15–18 ft. long by 3 ft. wide: spike very large, drooping; upper bracts covering the male fls. 8–10 in. long, persistent; male fls. about ½in. long, stalked; calyx 1¾in. long, more or less deeply lobed, lobes linear, hooded at apex; free petal ½–¾in. long, broadly elliptic, 3–5-lobed, the middle lobe oval and laterally toothed: fr. pyriform, about 4 in. long by 2 in. wide; seeds about ¾in. diam. German E. Afr., in deep wooded ravines at 3,600–3,800 ft. altitude.—Intro. into cult. in 1905. Decorative.

CC. *Seeds many, comparatively small (⅛–½in. diam.).*

D. *Foliage glaucous.*

E. *Lvs. mucronate pointed, thick.*

4. **religiòsa,** Dybowski. Whole plant about 8 ft. high, forming a true bulb like *M. Gilletii*, 2–2½ in. diam., but differing in having roots from the whole bulb instead of from the top of the bulb only: lvs. glaucous, oblong-lanceolate or elliptic, mucronate pointed, dying down, the bulb going through a resting-period: fls. undescribed: fr. full of seeds, inedible; seeds smooth, black, brown or gray. French Congo. R.H. 1901, pp. 157, 158.—The lvs. are thick and not easily broken by the wind. Considered by some to be more ornamental than *M. Ensete*. Intro. into U. S. about 1908.

EE. *Lvs. not mucronate pointed, thin.*

5. **Martrétii,** Cheval. Whole plant 20–25 ft. high: lvs. large, glaucous: fr. cylindrical, short, yellow; seeds smooth, black, ⅜–½in. diam. Guinea.—The fr. is edible, but the pulp is not abundant and of indifferent quality. A good ornamental for S. Calif. and Fla. Intro. into U. S. in 1908.

DD. *Foliage not glaucous.*

E. *The seeds tuberculate.*

6. **Livingstoniàna,** J. Kirk. St. conical, 10–12 ft. high, 2–3 ft. diam. at the base: lvs. crowded, narrow, oblong, as long as st.; petiole broad, clasping, deeply grooved: fr. 4 in. long, many-seeded; seeds ⅓in. diam., globose, angled by pressure, dull brown, tuberculate; hilum deeply depressed, surrounded by prominent edges. S. E. Trop. Afr., up to 7,000 ft. altitude.—Decorative. Yields a good fiber. Intro. into U. S. in 1907.

EE. *The seeds smooth.*

F. *Fls. 10–15 in a row.*

7. **supérba,** Roxbg. Whole plant 10–12 ft. high, not stoloniferous: st. 2–2½ ft. diam. at base, narrowing to 1 ft. below lvs.: lvs. 5 ft. long, oblong, narrowed to base; petiole very short, deeply grooved: spike at first globose, 1 ft. diam., one-third the length of st.; bracts orbicular, dull claret-brown, up to 1 ft. long; fls. in dense rows of 10–15 each; calyx 1 in. long, whitish, formed of 3 loosely cohering segms.; free petal short, 3-toothed with a long linear central tooth: fr. oblong, subcoriaceous, 3 in. long, 1½ in. diam.; seeds very numerous, ⅓–½in. diam., smooth, brown, subglobose, angled by pressure. India. B.M. 3849, 3850. G.C. III. 35:83. R.H. 1877, p. 277; 1888, p. 33. F. 1873, p. 273. Roxburgh, Plants of Coromandel, 3:223. Wight, Icones Plantarum, 2017.—Decorative, and yields a poor fiber.

FF. *Fls. 3–7 in a row.*

G. *Fr. 2 in. long: free petal ½in. long.*

8. **Gillétii,** De Wild. Whole plant 5–8 ft. high, not stoloniferous: lvs. about 5 ft. long: spike short, drooping; fls. 5–6 in a row; free petal 3-toothed, nearly ½in. long: fr. about 2 in. long; seeds 9 or 10, about ⅓in. long. Congo Free State.—Cult. in Fla.

GG. *Fr. 4 in. long: free petal ⅔in. long.*

9. **Arnoldiàna,** De Wild. Whole plant 12–15 ft. high, not stoloniferous: lvs. 7 ft. long, 13 ft. diam. at base: spike short, drooping; fls. 3–7 in each row; free petal 3-toothed, about ⅔in. long: fr. nearly 4 in. long; seeds 12–16, about ½in. long, smooth, broadly pyriform. Congo Free State. G.W. 9:401.—Decorative and showy. Cult. in S. Eu.

AA. *Sts. cylindrical; usually stoloniferous: male fls. many to a bract: fr. usually edible.* (*Subgenus Eumusa*).

B. *Fls. rose-red.*

10. **Mártinii,** Hort. Similar in habit to *M. paradisiaca:* lvs. oblong, long-petioled, firm in texture, bright green above, glaucous beneath with reddish veins: fls. bright rose-red: fr. small, yellowish. Intro. from Orotana Botanical Garden, Teneriffe, in 1893. R.B. 18, p. 107.—A good foliage plant for exposed places.

BB. *Fls. yellowish white.*

C. *Sts. short* (*1–6 ft.*)*: petioles short.*

11. **Cávendishii,** Lamb. (*M. chinénsis,* Sweet. *M. sinénsis,* Sagot. *M. hùmilis,* Perr.?). Chinese Dwarf Banana. Dwarf Jamaica. Whole plant 4–6 ft. high, stoloniferous: st. 2–3 ft. high: lvs. 6–8 in a dense rosette, spreading, oblong, 2–3 ft. long, 1 ft. wide, rounded at base, glaucous; petiole short, stout, deeply grooved; blades when young spotted and blotched with red: spike dense, short, drooping; bracts red-brown or dark, lower 6 in. long, upper 3–4 in. long; male fls. and their bracts persistent; calyx yellowish white, 1 in. long with 5 obtuse lobes; free petals about ½in. long: fr. as many as 200–250 in a bunch, oblong, 6-angled, slightly curved, 4–5 in. long, 1½ in. or more diam., obtuse, gradually narrowed to the sessile base, seedless, edible; skin rather thick; flesh delicately fragrant. S. China. Intro. from Mauritius in 1827. P.M. 3:51. Gn. 32, p. 243; 40, p. 263; 44, p. 496; 50, p. 161. G.C. III. 22:167.—Stands more cold than most bananas, and its dwarf growth readily allows for protection. Good for shipping and may be planted N. Extensively grown along the coast of the southern states and in the W. Indies.

CC. *Sts. tall* (*over 6 ft.*)*: petioles long.*

D. *Spikes erect or suberect.*

12. **Fèhi,** Vieill. (*M. Fèi,* Nadeaud. *M. Seèmanii,* F. Muell. *M. Uranoscópos,* Seem. *M. troglodytàrum,* S. Kurz., not Lour.). Stoloniferous: st. 15–20 ft. high, full of violet juice: lvs. larger and firmer in texture than *M. paradisiaca,* with stouter veins; base unequally rounded; petiole 1–1½ ft. long: spike long, erect, slightly curved at the base; fls. 6–8 in a cluster, sessile; calyx with 5 unequal lobes, finally splitting nearly to the base: free petal short: fr. many in a bunch, oblong, angled, 5–6 in long, 1 in. or more diam., nearly straight, yellow when ripe, skin thick; pulp moderately firm; seeds small, dull black. Tahiti and New Caledonia. Seedless at low levels but bearing seeds at elevations of 3,000–3,600 ft. G.C. III. 8:182.—Cult. in Eu. Fruits not very palatable when raw but excellent when cooked.

DD. *Spikes drooping.*

E. *Outer calyx-lobes with horn-like hooks.*

13. **téxtilis,** Née (*M. mindanénsis,* Rumph. *M. silvéstris,* Colla. *M. troglodytàrum textòria,* Blanco. *M. Abacá,* Perr.). Abaca. Manila Hemp. Whole plant 13–22 ft. high, stoloniferous: lvs. oblong, deltoid at base, bright green above, glaucous beneath, often with large brown spots; petiole 1 ft. or more long: spike drooping, shorter than lvs.; male fls. deciduous; calyx 5-lobed, about 1½ in. long, the outer lobes with a curved, threadlike horn near the apex: fr. obscurely 3-angled, curved, 2–3 in. long, 1 in. diam., not edible, filled with seed; seeds black, turbinate, ⅙in. diam., angled by pressure. Philippine Isls.—Furnishes one of the most valuable fibers known for the manufacture of rope. Cf. p. 171, Vol. I; also Cyclo. Amer. Agric., Vol. II, p. 286. Much grown in the Philippines.

Var. **amboinénsis,** Miq. (*M. amboinénsis,* Rumph.). Not so tall and spike not so drooping: fr. about 3 in. long, black at maturity. Amboina.—Cult. in the Philippine Isls. and used in the manufacture of Manila hemp.

EE. *Outer calyx-lobes without horn-like hooks.*

F. *Free petal nearly as long as the calyx.*

14. **Basjoò,** Sieb. & Zucc. (*M. japónica,* Hort.). Japanese Banana. Whole plant 12–18 ft. high, stoloniferous: st. 6–9 ft. high, 6–8 in. diam.: lvs. oblong, thin bright green, 6–9 ft. long, 1½–2½ ft. broad, deltoid at base; petiole stout, about 1 ft. long: spike dense, 1½ ft. long; female clusters 3–4, close, 12–15 fls. each; bracts oblong, dull brown, lower 8–12 in. long; male clusters 8–12, their bracts much imbricated, persistent; calyx whitish, 2 in. long, shortly 5-toothed at apex: fr. 30–60, oblong, pointed, 3-angled, 3 in. long, narrowed to a sessile base; seeds few. Liu Kiu Archipelago. B.M. 7182. R.B. 22, p. 152. R.H. 1896, p. 203. G.M. 54:376.—Cult. in Japan for fiber. Decorative and hardy as *M. Ensete.*

FF. *Free petal half the length of the calyx.*

15. **paradisìaca,** Linn. Plantain. Cooking Banana. Adam's Fig. Whole plant 20–30 ft. high, stoloniferous: st. 20–25 ft. high: lvs. oblong, thin, bright green, 5–8 ft. long, 1½–2 ft. wide, usually rounded at base; petiole 1–1½ ft. long: calyx drooping, often 4–5 ft. long; bracts mostly persistent, lanceolate or oblong-lanceolate, dull violet, more or less glaucous outside, the lower 1–1½ ft. long, the upper ½ft. long, often red inside, several expanded at once, the edges of the upper not involute; male fls. mostly persistent; fls. about a dozen to a cluster, yellowish white, 1½ in. long; calyx 5-toothed at the top; free petal oval, half as long as the calyx: fr. cylindrical, ½–1 ft. long, usually yellow or yellowish green when ripe, 40–80 in a bunch, flesh firm, not so sweet as the banana. Native of India. R.H. 1888, p. 69. L.B.C. 7:684. Redouté, Liliaceæ, 443, 444.—Universally cult. in the tropics, especially in the W. Indies and Cent. Amer. Not suitable to eat without cooking.

Subsp. (I) **sapiéntum,** Kuntze (*M. sapiéntum,* Linn.). Common Banana. Male fls. deciduous: fr. yellow, somewhat 3-angled, 3–8 in. long, 1½–2 in. diam. India. Trew, Plantæ Selectæ, 21–23. Rheed, Hortus Malabaricus 1:12–14.—Most of the commercial bananas are obtained from the numerous varieties of this subspecies.

a. *Fr. with thin skin.* (Subsp. *sapientum.*)

Var. (a) **Chámpa,** Baker (*M. Chámpa,* Hort. *M. oriéntum,* Hort.). Hart's Choice. Lady Finger, or Golden Early Banana. Chumpa. St. and midrib of lf. tinged with red: fr. pale straw-color, about 6 in. long; skin soft and thin; flesh luscious, delicate in flavor, ripening quickly.—Hardy in cool climates. Best of all for growing in Fla. Much grown in the W. Indies.

Var. (b) **rùbra,** Baker (*M. rùbra,* Firming, not Wall.). Baracoa, Red Jamaica, or Red Spanish Banana. St., petiole, fls. and midrib of lf. dull red: fr. at first dark red, ripening to yellowish red. This is the red banana of commerce formerly imported in large quantities from the W. Indies. Fine for decorative purposes but tender. G.C. III. 29:335. R.H. 1905:68.—The golden banana with fr. golden yellow or reddish, 8–9 in. long and blunt, is intermediate between this and var. *Champa.*

Var. (c) **cinèrea,** Blanco. Letondal or Chotda Banana. Fr. short, whitish, not angled, thin-skinned; flesh somewhat grayish; delicious; skin splitting and turning back at maturity; perfect seed frequently found.—Intro. from India by a French priest named Letondal. Cult. in the Philippine Islands and Guam.

aa. *Fr. with thick skin.* (Subsp. *sapientum.*)

Var. (d) **Dácca,** Baker (*M. Dácca,* Horan. *M. palùstris,* Hort.). Dacca Banana. St. pruinose: lvs. paler green than in the subspecies, glaucous beneath; border of the petiole red: fr. yellow, 4 in. long, 2 in. diam., tip and base bright green, skin very thick. India.—Flavor good. Tender.

Var. (e) **sanguínea,** Welw. Lvs. and fr. strongly tinged with blood-red.—Intro. into cult. in Eu. in 1903.

Var. (f) **vittàta,** Hook. Lvs. and long frs. copiously striped with white and rose: bracts bright red inside. Isl. of St. Thomas, W. Afr. B.M. 5402.—Very decorative.

Var. (g) **ternaténsis,** Blanco. Chotda Dama. Whole plant 5–6 ft. high: fls. about 20 to a cluster; calyx often coronate at maturity; free petal pitted at the outer tip: fr. with 3–5 prominent angles; seeds rare. Philippine Isls.—Cult. also in Guam. One of the most palatable varieties.

Var. (h) **mágna,** Blanco. Chotda Tandaque. Fr. 3- to several-angled at maturity, over 1 ft. long by 3 in. diam., more palatable when cooked. Philippine Isls.—Cult. also in Guam. Cloth is made from the fiber but it is not of as good quality as that from abaca.

Var. (i) **suavèolens,** Blanco. Bungulan. Fr. usually green, with yellowish spots at maturity; angles not conspicuous, obliterated at maturity; flesh fragrant and very palatable. Philippines.—Cult. in Guam.

Var. (j) **Lacatàn,** Blanco. Lacatan. Fls. about 14 to a cluster; calyx 5-toothed, the 3 alternate teeth large: fr. angled-obtuse at apex; flesh fragrant, firm. Philippines. Cult. in Guam. Blanco, Flora de Filipinas, 12:88 (1877).—One of the most palatable varieties.

aaa. *Fr. unknown.* (Subsp. *sapientum.*)

Var. (k) **oleràcea,** Baker (*M. oleràcea,* Vieill.). A flowerless form with a glaucous, violet st. and elongated, thick, turnip-like rhizome, which is boiled or roasted like a yam, and resembles it in taste. Intro. from New Caledonia, where it does not flower. B.M. 7802.—The tubers have "eyes" like a potato and the plant may be prop. by division. Cult. in Eu. where fls. have been produced but no fr.

Subsp. (II) **troglodytàrum,** Baker (*M. troglodytàrum,* Linn.). Spike erect in the lower half, drooping in the upper half: fr. small, crowded on the lower erect portion, oblong, cylindric, reddish yellow, containing rudimentary seeds; flesh sweet, yellow. India and Malaya. Blanco, Flora de Filipinas 12:88 (1877).—The favorite food of elephants. Rarely cult. in the U. S.

Subsp. (III) **seminífera,** Baker (*M. seminífera,* Lour.). Frs. small, oblong, full of seed, yellowish or greenish. Not edible. This apparently represents the wild seed-bearing form. Found wild in India, the Malayan and Philippine Isls.

AAA. *St. slender, cylindrical: male fls. few to a bract: fr. not generally edible: usually stoloniferous.* (*Subgenus Rhodochlamys.*)

B. *Lvs. green on both sides.*

C. *Rachis of the infl. glabrous.*

D. *Free petal nearly as long as the calyx.*

16. **Uranoscòpos,** Lour. (*M. coccínea,* Andr.). Stoloniferous: st. 4–5 ft. high, 2–3 in. diam.: lvs. oblong, 2–3 ft. long, 6–9 in. wide; petiole long and slender: spike erect, dense, about 1 ft. long; bracts brilliant scarlet, tipped with yellow, the lower 6 in. long; calyx yellow, 1 in. or more long; free petal nearly as long as the calyx: fr. oblong, 3-angled, not edible; seeds very small, rarely produced in cult. S. China. Botanists Repository 47. Redouté, Liliaceæ, 307, 308. B.M. 1559. L.B.C. 5:475. F.S. 7:722, 723. Martius, Flora Brasil. 3:1.—Intro. into cult. in 1791 and now widely distributed. Very showy. May be grown in 10-in. pots for winter decorations of tropical houses.

DD. *Free petal much shorter than the calyx.*

17. **Mánnii,** Wendl. Stoloniferous: sts. slender, cylindrical, tinged with black, 2–3 ft. high, 3½ in. circum. at base: spike erect, 6 in. long; female fls. in 3 clusters of 3 fls. each, their bracts deciduous; male bracts crowded, pale crimson, 3–4 in. long; calyx pale yellow, 1½ in. long: free petal much shorter: fr. small, 3–4 in. long, fusiform with a broad truncate apex. Assam. B.M. 7311.—Intro. into Eu. in 1893, and into U. S. in 1901.

CC. *Rachis of the infl. pubescent.*

D. *Free petal nearly equaling the calyx.*

18. **sanguínea,** Hook. f. Stoniferous: st. very slender, 4–5 ft. high: lvs. oblong, thin, bright green, 2–3 ft. long, 5–8 in. wide; petiole slender, 1 ft. long: spike at first erect, drooping when mature; female fls. in 2–6 clusters of 2–3 fls. each; male clusters few, dense; bracts lanceolate, somewhat persistent, blood-red, lower 6 in. long; calyx bright yellow, 1–1½ in. long; free petal nearly as long as the calyx: fr. oblong, 3-angled, rather pulpy, pale green variegated with red, glabrous, 2 in. long; seeds angled, small, black, tubercular. Assam. B.M. 5975.—Decorative and showy.

DD. *Free petal much shorter than the calyx.*

19. **rùbra,** Wall. St. slender, 4–6 ft. high: lvs. oblong-lanceolate, 1½–2 ft. long, 6–9 in. wide; petiole long and slender: spike dense, erect; bracts bright red, lower 1 ft. long and sterile, upper 2–4-fld.; calyx yellow; free petal half as long as the calyx: frs. in 3–4 clusters of 3–4 each, cylindrical, dry, 1½–2 in. long; seeds smooth, dull brown, ⅙in. diam. India. B.M. 7451.—Cult. in Eu.

BB. *Lvs. glaucous beneath.*

20. **sumatràna,** Becc. Whole plant 7–8 ft. high: st. slender: lvs. 5–6 ft. long, 1½ ft. wide, glaucous, with irregular blotches of claret-brown; petiole 1 ft. long; rachis pubescent: spike more or less drooping; lower bracts distant: fr. dry, cylindrical, curved, 2–3 in. long, ½in. diam. Sumatra, 1,100 ft. altitude. I.H. 27:375. F.S. 10:1061 (as *M. zebrina,* probably a young form of this species, and is very decorative).

BBB. *Lvs. red beneath.*

21. **rosàcea,** Jacq. (*M. ornàta,* Roxbg. *M. speciòsa,* Ten. *M. Carolinæ,* Sterler.). Whole plant 4–6 ft. high, stoloniferous: st. 3–5 ft. high, 3–4 in. diam.: lvs. linear-oblong, firm, 3 ft. long, 9–12 in. wide, purplish beneath: spike more or less drooping, 1 ft. long; bracts ovate-lanceolate, pale blue or reddish lilac, the lower 6–8 in. long; male fls. deciduous, more numerous than the female; calyx yellow, 1 in. long: fr. oblong, obscurely 4–5-angled, yellowish green, 2–3 in. long; pulp very scant, scarcely edible; seeds ⅙in. diam., black tubercled, rarely produced in cult. plants. India. B.R. 706. L.B.C. 7:615.—Intro. into Calif. in 1898.

M. assámica, Hort. Bull. Trunk about 1½ ft. high: lvs. about 1 ft. long, crowded, running out into a slender tendril-like point, green with a narrow purple border. Assam. This elegant dwarf plant allied to M. sanguinea is well suited for table decoration.—*M. imperiàlis,* Sprenger. A magnificent species with perennial rootstock and enormous somewhat lanceolate lvs. Related to M. Ensete. Kamerun. Cult. in Eu. Fls. and fr. not described.—*M. Rhodochlàmys,* Hort. A subgenus of Musa improperly used in some trade catalogues as a species. See species 16–21.

P. L. Ricker.

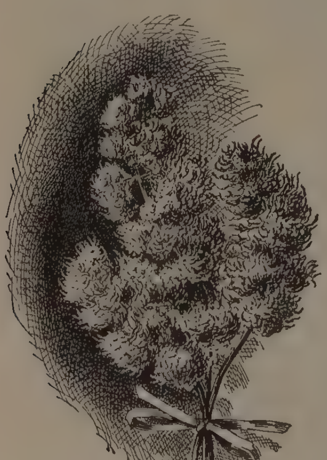
MUSÁNGA (W. African name). *Moràceæ.* One W. Trop. African tree allied to Cecropia, recommended abroad as shade in cocoa and coffee plantations and also as an ornamental foliage plant: lvs. large, alternate, long-petioled, peltate, divided into 11–15 entire segms.: panicle of small male fls. solitary in axils, of the female twin in the axils. *M. cecropioìdes,* Br. (*M. Smíthii,* R. Br., not Benth.), is described by Hiern as "a very elegant tree, 12–15 ft. high, branched a little above the base, with a broad head and good wood suitable for house-building: lvs. digitate; lfts. 6, 1–1½ ft. long; common petiole more than 7 in. long. (*M. Smíthii,* Benth, Niger Fl.=*Macaranga heterophylla,* Muell. Arg., a plant apparently not cult.)

MUSCARI (Latin name referring to the musky odor of *M. moschatum*). *Liliàceæ.* Grape Hyacinth. Excellent hardy spring-blooming bulbs.

Flowers in racemes or spikes; perianth urn-shaped, slightly or distinctly constricted at mouth; segms. 6-dentate, commonly reflexed; stamens in a double cylindrical tube; ovary 3-celled, sessile, globose-trigonal: caps. sessile, globose; seeds subglobose, black, glistening: bulbs membranous, tunicated.—About 45 species in Sicily, Algeria, European Medit., Spain, Asia Minor, and the Orient. All grape hyacinths are very much alike and are very interesting, botanically, horticulturally and from the artistic point of view. The group needs botanical revision badly. The chief literary sources are Baker in Jour. Linn. Soc., Vol. 11 (1871), and in G.C. II. 9:798 (1878); also Boissier's Flora Orientalis. The width of the lvs. is an important character, and Baker's measurements seem to refer to herbarium specimens. Live plants should be wider. (A line is a twelfth of an inch.) They are something like a hyacinth, but the clusters are smaller, and the individual fls. are smaller and of different shape, the grape hyacinths being constricted at the mouth and having 6 small teeth instead of the prominent perianth-segms., as in the true hyacinth.

The common grape hyacinth, which every garden lover knows, is called *M. botryoides*, which means "like a bunch of grapes." Everybody who has any ground for gardening should have some bulbs of this common kind, both blue-flowered and white. All the other kinds described below are fancier's plants, interesting chiefly to skilled amateurs. Among them the most remarkable is the feathered hyacinth (*M. comosum* var. *monstrosum*), which is a mass of lilac shreds (see Fig. 2404). Any species of Muscari is likely to have some sterile flowers at the top of the cluster which are often of a different color, but in the feathered hyacinth there is no suggestion left of the urn-shaped flower, sterile and fertile flowers all being cut into fine strips. This attractive plant has been sold for fancy prices by a few progressive florists.

Grape hyacinths are neat little early flowering bulbous plants, good-sized colonies of which give dainty effects in the border from February to May. There are numerous species of these, flowering at different times. They are mostly dark purple in color, either self-colored or tipped with white. There are also a few white and yellow forms, and several species with true blue flowers, the rarest color among flowers, though this would never be discovered in catalogues. *M. Szovitsianum*, one of the true blue forms, is quite the prettiest of the genus. The plant known to the trade as *M. lingulatum*, or *Hyacinthus azureus*, has the true blue of *M. Szovitsianum*, and is fully a month earlier. The usual forms grown in gardens are mostly blue (purple) and white forms of *M. botryoides*. *M. conicum* is very dark. The Dutch catalogues offer numerous kinds to suit amateurs and differing conditions. Muscari offer no difficulties in cultivation. A medium soil perhaps suits them best, but they are usually thrifty growers, and persistent in the garden if foliage is allowed to ripen. They mostly make offsets freely, and produce abundant seed. (J. N. Gerard.)



2404. Muscari comosum var. monstrosum.

Subgenus I. Moscharia. Perianth urn-shaped, but with a relatively long-tubular base; segms. minute, even for the genus, roundish, spreading and thickened on the back.

1. **moschàtum,** Willd. (*M. suavèolens,* Fisch.). Musk or Nutmeg Hyacinth. Lvs. 5–6, 1 ft. long, ½–¾in. wide: raceme loose, 1–3 in. long; fls. 20–50, blue. Asia Minor. B.M. 734. Gn. 26, p. 137.—Has the odor of musk. Seems to enjoy a warm dry border where bulbs mature properly. Sometimes fails to bloom after first year. Vars. **màjor** and **mìnor** are advertised. *M. dipcadi major* and *minor* have appeared in the catalogues since 1878, but these names have no botanical standing and represent cultural forms, of which there are several.

Var. **flàvum,** Lam. (*M. flàvum,* Van Tubergen. *M. macrocárpum,* Sweet). Fls. yellowish (Van Tubergen says clear yellow). B.M. 1565.

Subgenus II. Leopoldia. Perianth obovoid-urn-shaped, grooved above, 3–4 lines long; segms. triangular, reflexed, not thickened on the back: raceme loose, and longer than in the next. Particularly characterized by the conspicuous bearded appearance of the sterile fls.

2. **comòsum,** Mill. Lvs. 3–4, 1–1½ ft. long, ½–1 in. wide: raceme loose, 6–12 in. long, 40–100-fld.; lower fls. fertile, olive, tipped brown, borne on long horizontal pedicels; upper fls. sterile, blue or violet, borne on long upcurved pedicels, making a corymbose cluster. Medit. region, Orient. B.M. 133 (as *Hyacinthus comosus*).—An interesting form, but rare in cult., being greatly surpassed in popularity by var. *monstrosum*.

Var. **monstròsum,** Hort. Feathered Hyacinth. Fig. 2404. All the fls. sterile, and cut up into fine shreds. Gng. 7:290. A.F. 14:1286. Gn. 26, p. 137.—A most interesting plant. Also called fair-haired or tasseled hyacinth, and shredded lilac. Sold also as *M. monstrosum, M. plumosum, M. plumosum monstrosum,* etc. For other trade synonyms, see under *M. commutatum.*

3. **grǽcum,** Heldr. Differs from *M. comosum* in having its sterile fls. in a short, dense, conical spike, the pedicels of which are very short. Greece.

Subgenus III. Botryanthus. Perianth more or less urn-shaped, grooved or not above, 1–2 or rarely 3 lines long; segms. triangular, usually reflexed: raceme dense, 1–2 in. long. Sterile fls. inconspicuously bearded or hardly at all.

A. *Fertile fls. a little longer than broad, obovoid-globose.*

B. *Lvs. 3–4: fls. 12–20.*

4. **botryoìdes,** Mill. Common Grape Hyacinth. Fig. 2405. Lvs. linear-lorate, 3–4 lines wide: scape 6–9 in. long; fls. pale blue, odorless, 12–20. Eu., Orient. B.M. 157 (as *Hyacinthus botryoides*). A.F. 13:1197. Gn. 26:136. R.B. 20:3. Gn.M. 2:117.—The following varieties are offered: *álbum* (G.M. 51: 694. G. 27:235. Gn. 76, p. 106. Gn.W. 22:331. J.H. III. 58:464), *cárneum, cærùleum, leucophǽum, Lelièvrei,*

màjus, pállidum and *pállidum grandiflòrum.* These range from white through flesh-color to sky-blue.

BB. *Lvs. 5–6: fls. 8–12.*

5. **Héldreichii,** Boiss. Lvs. linear-filiform, subterete, 1½ lines wide: scape 4–6 in. long; fls. 8–12, amethyst-colored, with conspicuous white teeth. Greece. Gn. 26:136.

BBB. *Lvs. 2–3: fls. 6–10.*

6. **lingulàtum,** Baker (*M. Aùcheri* var. *lingulàtum,* Boiss.). Lvs. 3 lines wide: raceme ovate. G. 34:243 (as *M. azureum*). Asia Minor.—This is apparently a good species, but it is said that the plant sold under this name is the same as *Hyacinthus azureus* (Vol. III, p. 1616). Var. **prǣcox** is evidently a small form. Cilicia. Gn. 63, p. 75.

AA. *Fertile fls. 1½ times as long as broad, obovoid-oblong.*

B. *Color of fls. black-blue.*

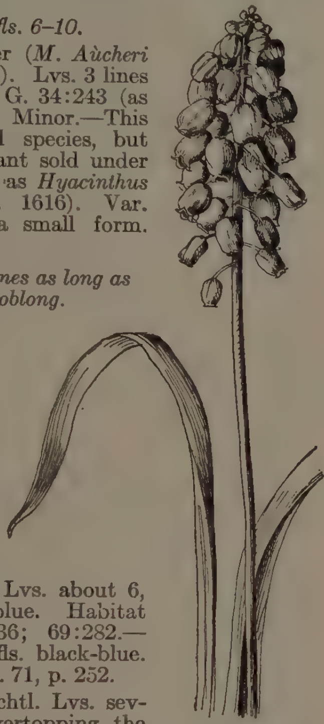
7. **paradóxum,** C. Koch. Lvs. 3, ½–¾in. wide: fls. rather longer than broad, deep black-blue. Armenia. B.M. 7873.

BB. *Color lively dark lilac or blue.*

C. *Lvs. ¼in. broad.*

8. **cònicum,** Baker. Lvs. about 6, narrower: fls. violet-blue. Habitat unknown. Gn. 51:136; 69:282.—Van Tubergen says fls. black-blue. Var. **álbum,** white. Gn. 71, p. 252.

9. **armenìacum,** Leichtl. Lvs. several, linear, much overtopping the raceme, reaching a foot at flowering: scape 4–6 in. long, tinted brown at base; raceme dense, 2 or more in. long; axis bright violet; perianth bright deep violet; teeth erect whitish; sterile fls. pale blue. Armenia.—One of the most handsome species, flowering the latest.



2405. Muscari botryoides. (×½)

CC. *Lvs. 1/12 to ⅙in. broad.*

10. **micránthum,** Baker. Lvs. several, overtopping the raceme: scape slender, 5 in. long; fls. bright violet, fragrant; sterile fls. few, sessile, pale blue. Habitat unknown.

11. **Szovitsiànum,** Baker. Lvs. several, 5–6 in. long: scape 4–5 in. long; fls. bright blue, considerably larger (⅙in. across, but only 1/12in. across in *M. micranthum*), faintly odorous: very large bulb, bearing several racemes of bloom. Persia, Caucasus. B.M. 6855.

BBB. *Color nearly white.*

12. **pállens,** Fisch. Lvs. numerous, filiform: scape 3–5 in. long; raceme 12–20-fld.; fls. white or nearly so. Caucasus, Iberia.

AAA. *Fertile fls. twice as long as broad, obovoid-cylindrical.*

B. *Lvs. almost cylindrical (subterete).*

13. **racemòsum,** Mill. Lvs. 5–6, 5–6 in. long, 1/12in. thick, almost cylindrical: fls. odorous, dark blue. Medit. Caucasus. B.M. 122 (as *Hyacinthus racemosus*). Vars. *cárneum* and *grandiflòrum prǣcox* are offered.

BB. *Lvs. oblanceolate.*

14. **latifòlium,** J. Kirk. Lvs. always solitary, ¾–1 in. wide, oblanceolate: sterile fls. 6–10, much paler than the others. Phrygia. B.M. 7843.

BBB. *Lvs. lorate, i.e., strap-shaped.*

15. **negléctum,** Guss. Lvs. numerous, 9–12 in. long, lorate, 1½–2 lines thick: fls. odorous, dark blue. Medit. region. Gn. 26:136. J.H. III. 61:249.—This differs from *M. commutatum* and *M. polyanthum* in having the segms. of the perianth triangular and reflexed. *M. negléctum multiflòrum* and *M. negléctum atlánticum* are trade names. See supplementary list under *M. Argæi.*

16. **commutàtum,** Guss. Lvs. 5–6, 5–6 in. long, 1½–2 lines wide: fls. odorless, dark blue; segms. very short, not recurved. Sicily.—Krelage advertises vars. *atrocærùleum comòsum, plumòsum, plumòsum monstròsum,* and *plumòsum violàceum.* It is apparent that he regards *M. comosum* and its forms as varieties of *M. commutatum.*

17. **polyánthum,** Boiss. Lvs. 2–3 lines wide. Differs from *M. neglectum* and *M. commutatum* in having longer pedicels and the caps. a half smaller, not more than 2 lines wide.

18. **compáctum,** Baker. Described only as *Botryanthus compactus* in an obscure work, which states that the fls. are nearly black, with whitish teeth which are semi-orbicular, obtuse, spreading-recurved. Baker places *M. compactum* next to *M. commutatum,* in spite of the fact that the original description says the fls. are obovate. Baker adds that this *M. compactum* is the *M. neglectum* of some authors in part. The plant in the trade as *M. compactum* may be a variety of some common species, since Van Tubergen says the fls. are pale blue.

M. Argǣi, little known botanically, is said to be extra good. In the trade, M. atlanticum is given as a synonym. Baker said he could not distinguish M. atlanticum from M. neglectum.—*M. atlánticum.* Consult the preceding entry, M. Argæi.—*M. azùreum,* Hort., is said by Van Tubergen to be the same as Hyacinthus azureus, which in turn is referred to H. ciliatus by Index Kewensis. Gn. 36:126. Van Tubergen also advertises var. amphibolis (M. Freynianum).—*M. Motelàyi,* is offered by Van Tubergen.

WILHELM MILLER.

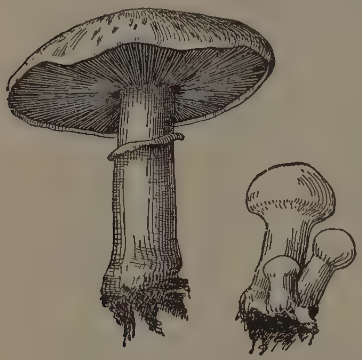
MUSÈNIUM: *Musíneon.*

MUSHROOM. The best usage sanctions the use of the word "mushroom" as a comprehensive term applicable to any and all of the higher fleshy fungi, whether good, bad, or indifferent with respect to edible qualities. With this usage it is then proper to speak of edible, inedible, and poisonous mushrooms of all types. From some quarters there is an inclination to regard only the agarics, or more especially the centrally stalked gill-bearing Agaricaceæ, under this name; thus we would have the field agaric, or field mushroom, the fly agaric, or fly mushroom, and so on. In a commercial sense, *Agaricus campestris* and the allies of this species are everywhere in America the dominant, and usually the only species of interest; so that among certain classes of persons it is not strange to find a tendency toward the restriction of the word to the commoner cultivated forms. The same persons with wider experience would doubtless abandon this usage, and employ the above-mentioned broader application now more generally used, which is also the one of the "mushroom" books.

Another use of the term is as a counterpart of toadstool,—"mushroom" denoting any edible species, and "toadstool" all the inedible or at least poisonous ones. With this criterion we would collect and throw into the "mushroom" basket all species as fast as they might in some way or other receive approval, and we would cast into the toadstool limbo all uncertain or untried and dangerous forms. On the basis of such distinctions, applied to European conditions, there might be on the markets of Munich, Germany, about fifty species for sale as "mushrooms," since this number is approved by the authorities; but in Berlin, at the dictation of stricter tastes, or rules, the number of recognized "mushrooms" would be scarcely half that of Munich. "Toadstool" is a term which might well be held sacred to the fairy tales of mushroom life.

It seems probable that mushroom is derived from the old French mouseron or moucheron, now mousseron. An obsolete English form is musheron, while mushrump and mushrome have also been used. Among consumers of French canned "champignons" (fungi) there seems to be the feeling that this general term is used only for the cultivated forms, but this is merely a special trade use, and even in popular mushroom books the cultivated forms are carefully distinguished as "champignon de couche."



2406. Agaricus campestris (the true mushroom). (×½)

The only mushrooms cultivated extensively in Europe or America are the "common mushrooms," or field mushrooms, consisting probably of several closely related species, which are usually designated *Agaricus campestris.* In reality, there is a group of species, including at least *A. arvensis, A. campestris* and its near relatives, *A. villaticus,* probably *A. Rodmani* and *A. fabaceus,* any of which may be cultivated. It is not too much to hope that in time representatives of several other genera of the fleshy fungi may be cultivated for special purposes, but it is doubtful whether any species in culture would yield more abundantly than do the forms now grown. These species closely resemble one another in general characteristics and in life history, so that a description of a common type of *A. campestris* will define all with sufficient accuracy for the present purpose, and it will indicate in general the terminology of all the Basidiomycetes, that is, the class of fungi which contains the larger part of the fleshy forms.

Characteristics of Agaricus campestris (Fig. 2406).

The full-grown expanded plant is somewhat umbrella-like, with a central stalk (stipe) supporting a rather thick cap (pileus). The stem may be from 2 to 5 inches in height, about 1 inch in diameter, and above the middle there is typically a ring or annulus, but there are no other appendages about the stem. The cap bears on the under surface the gills, blade-like lamellæ reaching for the most part from near the stem to the periphery of the cap. When the cap of the young mushroom begins rapidly to expand, it breaks away from its attachment to the stem, and the veil of tissue which has hidden the gills from view is ruptured at the periphery of the cap, leaving the ring or annulus already mentioned. When the gills are first disclosed they are of a beautiful pink color, but with age they darken and ultimately become brown-black.

The coloration of the gills referred to is due chiefly to the formation of spores or propagative cells, in large number. If one places the cap of a maturing mushroom on a piece of white paper, gills downward, protecting the cap from rapid drying out, a perfect spore print of the brown-black spores may be made. The number of these produced by a single mushroom expressed in figures is too great to be adequately grasped. The spores are small ovoidal cells, as shown in Fig. 2407, and they are borne upon club-shaped structures termed basidia,—these being organs which are characteristic of the whole class of the Basidiomycetes. The entire surface of the parallel gills is studded with the basidia, each basidium bearing from two to four spores.

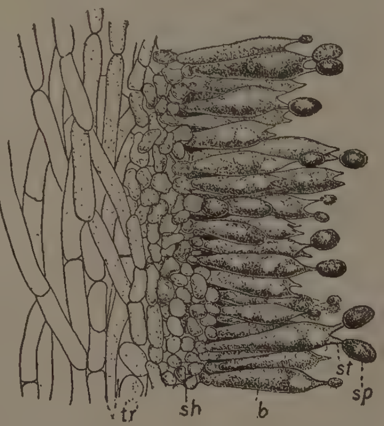
Vegetative and fruiting stages.

In the open the spores doubtless germinate, but the conditions for their germination are not so well understood that they can be readily duplicated in the laboratory. At any rate, germination of the spores yields a mycelium or thread-like growth that is characteristic of most fungi. The development and growth of the mycelium in rich earth, compost, or manure yields a characteristic "spawn," for "spawn" is merely the abundant development of the mycelium, or vegetative stage of the fungus, in any suitable substratum. In this connection it is well to note that the mycelium of other fungi may invade a great variety of substrata. Rich earth, the moist leaves of the forest floor, fallen timber, and even the trunks of living trees are all invaded by a variety of species, each having its particular growth-requirements. Fresh spawn of *Agaricus campestris* has a fine aroma of mushrooms combined with that of almonds. By this aroma alone it may be easily recognized, and therefore distinguished from the mycelium of common mould fungi. By pure-culture methods, mushroom spawn may also be developed from fragments of the tissue, as subsequently indicated. Spawn is appropriately called the vegetative stage of the fungus.

The mycelium not only absorbs from the substratum the necessary water, together with the organic and inorganic food materials necessary for its immediate growth, but obviously there is accumulated a considerable amount above the growth needs, which serves as a fine adjustment to the heavy demands for food made somewhat later when fruiting begins. With a vigorous development of spawn in earth or compost, fruiting, or mushroom formation, will proceed. At this time the threads of spawn become more strongly corded and matted, attended by the formation of spherical "pinheads," and the latter develop directly into the well-known "button" stages, the appearance and rapid development of which give such satisfaction to the novice in mushroom-growing. With the increase in size of the button and the differentiation of gills, there is next a rapid expansion of the cap and the elongation of the stem, followed by the rupture of the veil. The mushroom is then full grown, at which time the shedding of spores begins.

Mushroom-culture.

In times past, it has been the custom to regard mushroom-growing as more or less of a mystery. It was therefore considered impossible to lay down specific rules for the guidance of others. This was due primarily to the fact that there had been very little experimental work from which to deduce the principles on which successful culture depends. There is now no reason why an intelligent person should not be able to produce mushrooms successfully if he



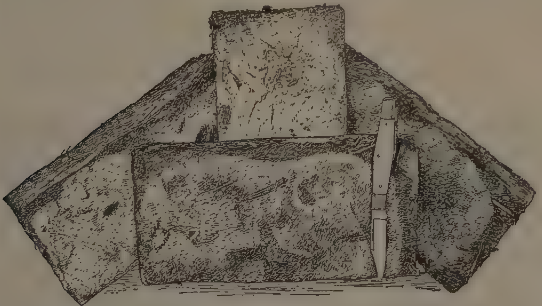
2407. Section of a gill of Agaricus campestris, enlarged: *tr,* trama; *sh,* hymenium; *b,* basidium; *st,* sterigma; *sp,* spore.

is able to give to his work the care and attention which would be bestowed upon the cultivation of delicate flowers or the rearing of poultry.

Within the past dozen years, sufficient has been done to demonstrate the fact that the general principles of production are comparatively simple. The limits of conditions permitting production are narrower than those usually applying to other horticultural crops, yet it is true that the principles in the one case are just as definite as in the other. To state this in terms of its causation, it may be said that many of the more important biological problems concerned in the growth of mushrooms are sufficiently understood to enable us to comprehend the meaning and relative values of the practices which have grown up about this industry, and in many instances to modify these practices advantageously. As a matter of fact, since mushrooms should be grown only in situations which permit the practical control of conditions—that is, of the substratum or compost, the amount of moisture, the temperature, and other factors of the environment,—it should now be, and in the hands of many growers is, a more certain crop than many others commonly regarded as table necessities.

It is no uncommon thing to hear the question asked, "Why is it not possible to produce mushrooms successfully in fields and lawns?" This question might be answered by anyone who reflects for a moment on the commercial success or failure of the pasture and lawn occurrence of mushrooms. One could predict that dandelions would be a successful lawn crop because whether one wills or no they are produced on our lawns in quantity, and sometimes they threaten to take possession where they may not be wanted. Mushrooms also occur in the lawn and field, but how sporadic and unreliable is the supply! One expects to find them in the early fall, but if they are not found, or occur in very limited quantity, it is easy to explain their absence on the ground of insufficient rain, unexpected cold weather, early summer drought, or other obvious causes. This merely indicates that mushrooms are not in any way commercially successful in such situations.

Mushrooms are indeed very sensitive to conditions, and commercial out-of-door culture is possible only in a region where the temperature conditions are fairly uniform throughout a considerable period of time. Moisture is not quite so important, because even in the open this often may be adequately controlled. Out-of-door culture is practised to a limited extent in England and in France, but in no section of the world is the common cultivated mushroom grown in the open successfully to compete with the product produced in mushroom-houses, cellars, or caves. Owing to the overwhelming importance of the indoor culture, therefore, it is only necessary to describe this as of commercial importance.

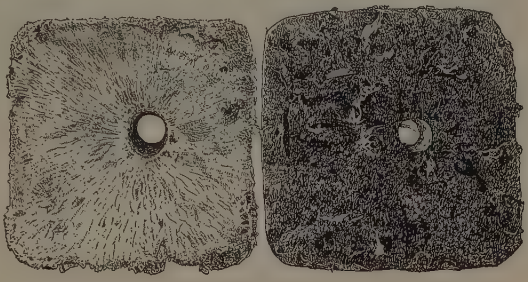


2408. Common commercial spawn of Agaricus campestris.

It was stated above that rules may be laid down for the cultivation of this crop. Rules must be in a measure arbitrary if they are to be successfully applied by the beginner. One who has mastered the principles may vary these advantageously for all changes of conditions. The more important factors involved in mushroom-growing, and about which recommendations must center, may be enumerated as follows: compost, spawn, temperature, moisture, and sanitation.

Compost.

Stable-manure furnishes the only satisfactory compost known for commercial mushroom-growing. By a suitable period of fermentation, or composting, the manure becomes more suitable for the growth of the mushroom spawn and less likely to support the succession of mould fungi which would otherwise first run its course. The manure should contain ample bedding material. Straw, shavings, and sawdust are used for this purpose; but straw is preferable from the mushroom-growing viewpoint, as it not only reaches in a short period of time a certain desirable stage of decomposition, but good straw makes likewise a substratum of excellent texture and water-holding capacity.



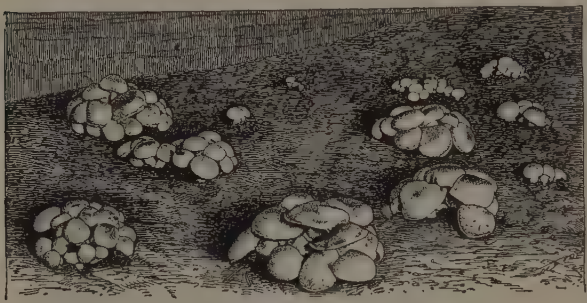
2409. Spawn of Agaricus campestris, pure culture.

When the amount of fresh stable-manure is sufficient, it should be wet and somewhat packed. In a few days the temperature will rise to perhaps 120° to 140° F., which is indicative of an active fermentation. The compost is then forked over, or "turned," care being taken to mix the outer with the inner material, and water is sprinkled upon it whenever needed to maintain the compost in a condition which is moist throughout. With straw manure, it is often sufficient to "turn" three times, but a somewhat longer fermentation is not harmful. The turnings may be after intervals of three to five days, the total time required for fermentation in summer being from eighteen to twenty days. When shavings and sawdust occur in some quantity, a longer interval will be required. As soon as the fermentation is complete the beds may be prepared, as described on page 2085.

Spawn (Figs. 2408, 2409).

Prior to 1903 no mushroom spawn had been made in the United States, the larger part of the spawn used being brick spawn imported from England. French flake spawn was also used to some extent. Pure cultures derived by the tissue culture method were first employed by the writer as a source of material for the inoculation of bricks in 1903. Since that time the brick spawn-making industry has become successfully established in this country. In fact, the enormous development of mushroom-growing within the past ten years has been due more to reliable spawn and to the dissemination of information explaining the growth-requirements of these plants than to all other causes combined.

The percentage of failures by amateur growers has steadily declined. It is not to be understood, however, that all failures are due to poor spawn. Still, when one hears the complaint that "the cellar was constantly at a temperature between 50° and 60° F., and not a mushroom appeared," one can be fairly certain that the spawn was dead. Other causes may determine a poor crop, but seldom no crop. In spite of the fact that reliable spawn is now made, some small dealers will, of course, continue to offer for sale old spawn which has lost all vitality just as they may offer old seeds. It is necessary to be even more careful in the purchase of spawn than of field or garden seeds. Experiments have shown that spawn stored under the conditions which usually prevail in the cellars or basements of seed-stores is seldom alive for more than one year after it is made.



2410. Mushrooms growing in a cellar.

Temperature.

The most favorable temperature for mushroom-production is about 54° F. Perhaps there is no appreciable difference between 52° and 56° F. More important as principles are the limits of temperature, and the effects of more or less heat than that mentioned. No one should attempt to grow mushrooms in any house or cellar where the temperature is constantly above 60° F. In the warmer atmosphere, all kinds of insects and other mushroom enemies will be active; in fact, insects that are practically torpid at 50° may be extremely harmful and multiply rapidly at 60° F. Apparently at 60° F. the spawn in the beds will be affected more or less by the growth of other organisms, the requisite humidity is not so readily maintained, and "fogging off" is frequent. Moreover, even if the higher temperature lasts only a few days at a time, the quality of the product will be affected. In hot weather the mushrooms are smaller, long-stemmed, and quickly expanded. At a temperature continuously 45° F., mushrooms will develop so slowly as to be unprofitable. A few days of low temperature is not in any sense injurious, for it merely causes delay in production. If one wishes to obtain particularly heavy mushrooms, this can be best accomplished by keeping the temperature fairly low, and occasionally permitting it to fall below 50° F. for a few successive days. Even light freezing does not kill the mycelium in the beds.

Moisture.

It has been noted that after the first watering when the stable-manure is being prepared for compost, the rule is "moist but not soaking wet." No better rule can be given. It is scientifically more accurate to say that the compost in the beds should contain about 60 to 65 per cent of its oven-dry weight of water, but the best practical test of 60 to 65 per cent is that when compressed firmly in the hand it will moisten the hand but drops of water will not be squeezed out with ordinary exertion. When the beds are cased, the surface soil must also be kept moist. Even if the compost below is moist, no satisfactory mushrooms will be produced in a dry soil. On the other hand, to keep the soil wet it is not necessary to drench the bed. The latter serves to make the compost too wet, and the soil may soon be dry again. In the ideal mushroom house, watering should be required to the extent of no more than one light sprinkling each day; but in small cellars or houses where the heating is by means of stoves, or other similar dry heat method, more frequent sprinkling will be required. The humidity of the atmosphere should be from 60 to 75 per cent. There should be a gradual but slow evaporation. Walls and ceiling may be conveniently sprayed, when necessary, with a Vermorel spray nozzle.

Sanitation.

Sanitation involves (1) good drainage and ventilation, (2) removal of all waste mushrooms, also the clotted and spent mycelium at the bases of mushroom clusters, and especially fogged specimens, and (3) the trapping of insects, whenever they become evident, as well as the regulation of conditions, if possible, so as to prevent their activity. Drainage is a minor matter if the application of too much water is assiduously avoided. Ventilation is particularly necessary in caves and low cellars. Waste mushroom material, whether on the bed or about the cellar, is a constant menace. When mushrooms are picked in clusters, the little buttons in the vicinity which are injured should be removed. All old bases of clusters should be lifted and a handful of fresh earth applied.

Where mushrooms may be grown (Figs. 2410, 2411).

Since the control of conditions is the essential point in the culture of these fungi, it is obvious that mushrooms may be grown in any house, cellar, or cave which will permit the regulation of moisture and temperature, and incidentally of ventilation. It is not the purpose of this article to attempt the discussion of the various types of construction which may be employed in the erection of suitable houses for mushroom work. Any kind of building material may be used, but since a considerable amount of water is necessarily employed, it is well to provide against "sweating," and the drip which accompanies this. As a rule, an air-space in walls is an effective preventive of this condition. The ceiling of the mushroom house may be high or low, depending upon the number of tiers of beds to be used. When it is desired to place the beds on the floor only, the ceiling should be as low as will permit men to work comfortably; for the additional air-space above the bed will be disadvantageous with regard to the control of both heat and moisture. Persons who are making a first trial with mushroom-growing, or those who intend to use a small amount of space for the production of a small quantity intended merely for home consumption, will preferably choose for the purpose any cellar, shed, or other space which may be available. Such space may be adapted more or less

2411. Mushroom-growing in a portland cement cave.

to the special use to which it is put by temporary partitions, false floors, or by other means which will suggest themselves. In those cases in which cellars or caves are used, it is important that there shall be good ventilation. So-called "stagnant" air is almost as bad in mushroom-growing as in greenhouse work. In such air, moreover, the mushrooms will tend to become long-stemmed and the caps will be relatively small. The amount of ventilation will depend upon circumstances, but in all cases it should be sufficient so that there will be a constant, but slight drying of the beds from day to day, requiring occasional sprinkling. There are probably only a dozen places in the United States where mushrooms may be grown advantageously in mushroom beds in the open, and this is primarily due to the variability of the temperature, but partially also, to the difficulty of maintaining the requisite humidity.

Preparation and care of beds.

When the stable-manure has been composted for a period of eighteen to twenty days, it will have lost practically all objectionable odor, the temperature will probably have fallen to 120° to 130° C. (248° to 266° F.), and the texture will be adhesive or oleaginous. In this condition, it may be made into beds. The type of bed commonly employed in the United States and England is a flat bed from 6 to 8 inches deep, and from 2½ to 4 feet wide, depending upon whether it is accessible from one or from both sides. In France the ridge bed is more commonly employed. Somewhat more labor is required in the construction of the latter, but the surface area is considerably increased. The ridge-bed system is seldom employed when the beds are arranged in tiers. It is far more applicable to the growing of mushrooms in caves or cellars. The use of flat beds in tiers, or in the nature of shelves, will often permit one to multiply to the extent of four- or five-fold the amount of available space.

The compost is thrown into the space to be occupied by the bed, arranged as required, and immediately "firmed." The beds should not be hammered down with a wooden mallet as is the custom with some growers. Usually the temperature of the bed rises after the first day, and the maximum is promptly attained. Within a few days the temperature will begin to fall and the bed may be spawned at 70° to 75° F., with the temperature on the decline. In no case should the amateur grower attempt to spawn his beds when the temperature is above 75° F. It does no harm at all to spawn at 60° to 70° F., but a growth begins somewhat more rapidly at the temperature first mentioned. Within a week or so, the temperature should fall to that which has been mentioned as normal for mushroom-growing, that is, about 54° F.

When brick spawn is used, each brick may be broken into about twelve pieces, and one piece will be required for each square foot of bed space. Insert each piece from 1 to 2 inches below the surface, holding it with one hand while pressing the compost firmly about it with the other hand. In the course of about ten days the new growth should become evident about each piece of spawn, and when an examination of the bed discloses this fact, the bed may be smoothed and again firmed, or slightly compressed, such that a person might stand on it without sinking in the substratum more than from 1 to 2 inches. If there has been any drying of the surface layers, the beds should be sprinkled, and it is then ready for the "casing" of loamy soil. A good casing soil is an ordinary light loam, but almost any good garden soil is serviceable for this purpose. The presence of a considerable amount of woods mold in the soil is to be avoided. The soil is applied evenly to a depth of 1 to 1½ inches, and it should be firmed as applied.

Subsequent to the casing, the beds will require no attention except with respect to the regulation of temperature and moisture. The soil should be kept constantly quite moist, but water should never be applied copiously while the spawn is spreading. Employing good spawn, mushrooms should begin to appear in six to seven weeks, although a longer period of time may be required if sawdust or shaving compost has been used. Under uniform conditions, mushrooms will appear quite regularly all over the bed, and they will, especially at first, have a tendency to come in flushes. When the first flush has been picked, there may be an interval for that bed of several days, or a week, before a second flush will appear.

In harvesting mushrooms, it is usually best to take them before or just at the time that the veil begins to break. At about this time they will have attained their maximum weight, and they make a far better appearance than later. The common method of harvesting requires the operator to take hold of the cap firmly, twisting it slightly, as a result of which the mushroom is often removed from the bed without cutting. When, however, the mushrooms grow in clusters, the assistance of a knife is needed; and it is often possible to remove those sufficiently developed without endangering the growth of smaller ones in the cluster. In preparing the product for the market, the basal portion of the stem is cut off, and the plant is brushed with a medium-sized paint-brush so that it is made free from soil-particles. The best markets require that the product shall be graded into large, medium, small, and old mushrooms. Small growers, however, can seldom afford to adopt this system, and they should cut with such regularity as will insure a fairly uniform size.

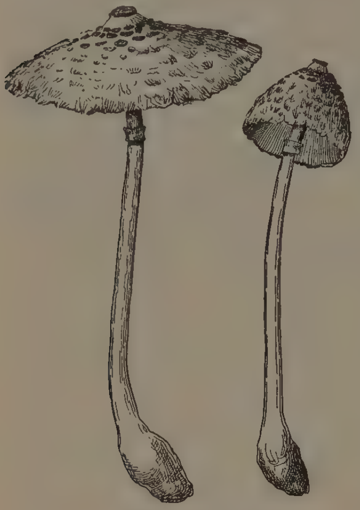
Mushrooms, families of.

The cultivated mushroom is one type of the Agaricaceæ, a family in which the spore-bearing, or fruiting surface (hymenium) is in the form of leaf-like plates, or gills. The spore prints of the fifty or more genera of this family vary in color from near black through all shades of brown and ochre to pure white.

Agaricus campestris, the common cultivated mushroom, or field mushroom, has already been described. It is important to note for this, as for all species of the genus, the brown-black spores, the central stalk, the characteristic ring or annulus, and the gills changing from pink or light brown to brown-black free from the stem. In general, *A. campestris* possesses a simple ring, the stem is fairly uniform in diameter, and the cap varies from a cream-color to various shades of brown or gray-brown. The upper surface is usually smooth, but with alternate wet and dry weather or, as a result of the growth in rooms with variable artificial heat, it may be broken into more or less diamond-shaped areas exposing the white flesh. There are probably several cultivated varieties of this species, but it is often difficult to determine whether a given variety in culture belongs to this or to some related species. Three trade forms—based largely on color—are generally recognized, but within these color limits there are undoubtedly many varieties. The three trade names referred to are: "Alaska," relatively small, white or very light gray forms; "Bohemia," large brown varieties, one of which at least may be *A. campestris;* and "Columbia," which is the name for the large cream-colored forms which may apparently be referred to one of several species.

Agaricus arvensis, ordinarily known as the horse mushroom, has much the same season and habitat as *A. campestris*, and forms occur which seem to be intergrading. Typical forms of the horse mushroom are larger and stouter than the field mushroom and distinguished from the latter by the possession of a double ring. There is some diversity of opinion regarding pileus (color) characters; but in any event there would appear to be several varieties in cultivation which may be properly referred to this species. Under cultivation the writer has been unable to find any better flavor in *A. campestris* than in *A. arvensis*. *A. Rodmani* and *A. villaticus* are closely related to *A. arvensis* and *A. campestris*, but there is some doubt as to whether either of these should be regarded as distinct species.

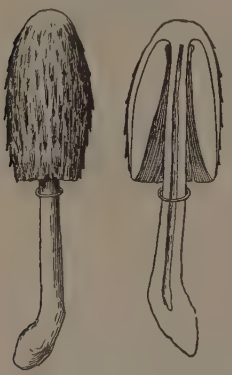
Agaricus fabaceus (*A. subrufescens*) is the almond-flavored and almond-fragrant mushroom, sometimes found in greenhouses or in flower-beds. This species is readily distinguished by (1) the long-persistent membranous veil, the lower surface of which is covered with soft frosty scales; (2) the red-brown to gray-brown (with age) pileus; and the enlarged lower part of the stem. It has been cultivated, but requires a higher temperature than *A. campestris* and is said to be less prolific. It deserves further trial. The spawn grows vigorously in the usual bricks. *A. placomyces* is a woodland species, and it is sometimes found from early summer until late fall. The cap is large, flat, and thin, appearing smoky above from the presence of numerous small, dark scales, which are closer together near the center. The veil is like that of *A. arvensis*, and the base of the stem is enlarged. The writer has made spawn of this species, and cultivated it in small quantity.



2412. Lepiota procera. Parasol fungus. (×⅓)

Agaricus silvicola, also an inhabitant of woods, is almost pure white except as to gills. It is sometimes tinged with yellow, and is always a rather small species, occurring in the summer. Its value in cultivation could be only with relation to its resistance to high temperature.

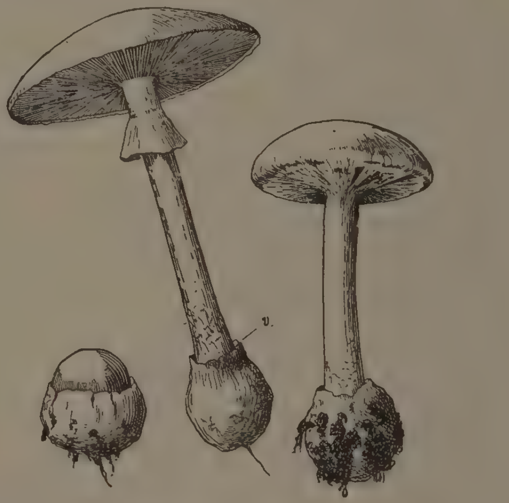
The question of temperature-resistance is an important one, however, and the discovery of an acceptable edible species which might be grown at from 60° to 70° F. would make it possible to extend the mushroom-growing season to ten or eleven months.



2413. Coprinus comatus (Horsetail mushroom).

Coprinus.—Aside from Agaricus, Coprinus is the only other genus of the Agaricaceæ with black spores which is sufficiently important from an economic standpoint to require consideration. The genus is characterized more particularly by the deliquescence of gills and other parts of the pileus at maturity to an inky black liquid. There are three edible species of common occurrence, appearing usually in lawns in the spring. *C. comatus* (Fig. 2413), the shaggy-mane mushroom, is the largest, and one of the best of the fungi. The whole plant is often 6 inches in height, with a cylindrical cap frequently not less than 3 inches long and 1½ inches in diameter. The name is derived from the shaggy scales on the pileus. As the plant approaches maturity the gills are of a salmon-color and there is a free or movable ring. *C. atramentarius*, the true ink-cap, is a shorter form than *C. comatus*, and it commonly occurs in clusters. The shorter, oval cap is slaty gray in color, due to the background of dark gills showing through the hygrophorus tissues. *C. micaceus* is much smaller than either of the preceding, and occurs often in solid phalanx covering several square feet of space about old stumps or over decaying roots. When young, the tan-colored cap is covered with temporary, glistening scales, like minute particles of mica. The only disagreeable feature about the Coprini is their deliquescence, but they are of fine flavor and quality, if eaten fresh.

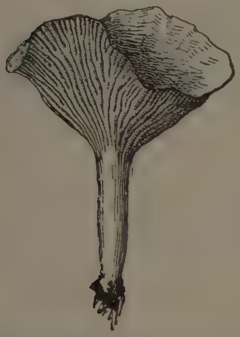
Lepiota.—The genus Lepiota corresponds to Agaricus in general characteristics, except that the spores in the former are white. There are many species of this genus, of which the more important are *Lepiota procera* (the parasol mushroom) and *L. naucinoides*. Both are found widely distributed in lawns, fields, or meadows. The parasol mushroom is one of the most conspicuous of the edible agarics, standing frequently 10 inches high with a pileus often 5 to 6 inches in diameter, reddish brown in color, with darker blotch-like scales. The stem is delicate except for the bulbous base. The ring is large and free. *L. naucinoides* in prime condition is usually pure white. It is about the average size of the cultivated mushroom, but with a thinner cap and a stem more slender, thickening toward the base. One who is not an expert should remember that the deadly amanita is also white. See *Amanita*, below.



2414. Amanita phalloides, poisonous. V. volva. (×⅓)

Armillaria mellea, the honey agaric, commonly brownish yellow in general appearance, is typically an autumn plant growing in clusters about stumps and the bases of trees, or appearing through the sod over decaying roots. It is one of the more abundant mushrooms in wooded sections. In form this plant differs from Lepiota largely in the fact that the gills are attached to the stem. The spores are white but the gills become discolored with age. This species is parasitic on a number of trees. The mycelium develops a characteristic cord-like, or rhizomorphic stage. This plant is acrid and disagreeable raw, but cooked it is said to be of good flavor.

Amanita.—The genus Amanita is interesting for two reasons: (1) because it contains some handsome species, which are quite likely to attract the attention of every beginner in identification; and (2) because among these species there are several which are the most deadly poisonous of all mushrooms. Unless one is an expert, therefore, it is well to learn the characters of the genus in order to avoid any inclination toward using them for food. The genus contains, it is true, several edible species, and when one knows them there is no danger. Amanita possesses all of the general characters of Lepiota, likewise certain additional ones which serve clearly to distinguish it. The white spores (and usually white gills), the annulus, and gills free from the stem are just as in Lepiota; but there is in Amanita also a volva, or universal veil, which in the mature mushroom appears usually as a cup at the base of the stem, and sometimes remnants of it are carried up by the pileus as frosty scales. In the button stage this universal veil is an outer skin or envelope, and as the plant expands it bursts through the envelope leaving more or less of a cup, or at least a basal ring, at the base; and if the upper part of the envelope adheres to the cup, it is broken into mere scales, or frosty patches, as the pileus grows. Now if one pulls up an Amanita carelessly, the volva might not be detected. On the other hand the ring, or veil, might be broken, and then with a volva and no ring the plant might be mistaken for an Amanitopsis—a genus with many edible species. Young stages in meadows have been mistaken, indeed, for buttons of *Agaricus campestris*. The *Amanita phalloides*, deadly amanita (Fig. 2414), is widely distributed in the United States, occurring especially in woods and meadows. The plants may attain a height of 6 inches and a pileus diameter of 4 inches. In general appearance it might be mistaken for a Lepiota, especially *L. naucinoides*, as some forms of the species may be entirely white. As a rule, however, the upper surface of the cap is grayish, brownish, or greenish. Usually, there are no scales, at any rate no small scales, on the cap, and the volva is cup-like. *A. verna*, the destroying angel, is a pure white plant, regarded by some as one of the white forms of *A. phalloides*. *A. muscaria*, the fly agaric, is only somewhat less poisonous than those above mentioned. It is one of the handsomest mushrooms of the forest. The plant may be larger than *A. phalloides*, and the cap varies from yellow to orange-red in color, with frosty or creamy white scales or patches. In this species the volva is not so prominent, since the universal veil breaks transversely into a number of small incomplete rings, which remain at the base of the somewhat bulbous stem in the form of interrupted rings of scales. The gills and stem are white. *A. Cæsarea*, the royal agaric, has also an orange-red cap, but in this species there is a very definite cap-like volva, and the gills of the plant are yellow to orange. This species has been much prized since the earliest historical times, but no one should attempt to use it who is not able clearly to distinguish the different species of Amanita.



2415. Cantharellus cibarius (chanterelle). Edible. (×⅓)

Tricholoma personatum, the masked tricholoma, is a representative of a genus differing from Lepiota in possessing no ring, and further in having the gills attached to the stem, yet notched near the point of attachment. This species is usually pale violaceous or lilac when young, and the pileus is plane or distinctly wavy. The flavor is esteemed. It has been cultivated in experimental beds.

Clitocybe.—In this genus the spores are white and the gills are not only attached but decurrent upon the stem. *Clitocybe velutipes* grows in clusters about stumps and trees, and is readily recognized by the bright red-brown viscid pileus, the pale yellowish gills, and the dark stems clothed at the base with a growth of hairs velour-like in texture. This fungus is a late fall and winter mushroom, prized by many, in spite of an apparent toughness in the raw state.

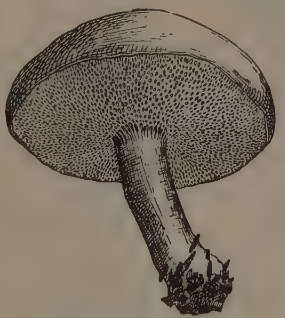
Pleurotus.—The members of this genus which are of special interest horticulturally grow on decayed places in the trunks of trees, or on logs, and they are readily distinguished from all other white-spored agarics by the excentric stem. It is typically a clustered mushroom—the clusters being sometimes of enormous size. The plants are white or lightly tinted, and the gills are generally decurrent. *Pleurotus ostreatus*, *P. sapidus*, and *P. ulmarius* are the commoner large species, all of which are edible, but not keenly sought.

Lactarius, the mushrooms which yield a milky juice when the gills are cut or injured, is represented in our woods by several species, of which the commoner edible ones are *Lactarius deliciosus* and *L. volemus*. In form these plants are much like a Clitocybe, but the gills are not strictly decurrent. *Lactarius deliciosus* is yellow-buff or light orange, mottled with darker spots or zones, and the juice is orange-colored. The plant is often about 4 inches high and the pileus about 3 inches in diameter. *L. volemus*, a somewhat smaller plant, is of uniform color, brown-orange, or tawny, with white juice. The peppery lactarius, a large white species, is very acrid. Closely related to Lactarius is the genus Russula,—lacking the milky juice,—of which many species with pilei white, greenish, violaceous, or red are found in our woods in summer and early autumn.

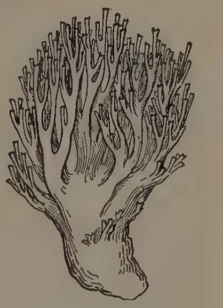
Cantharellus cibarius (Fig. 2415), the chanterelle, is one of a group the members of which are barely agarics, for the gills are often almost vein-like, rounded on the margin and often reticulate. The chanterelle is uniformly yellow to orange in color, small, more or less unsymmetrical in form. It is also an inhabitant of the woods, and it is much used as a vegetable food in Europe.

Other Basidiomycetes.

It has been indicated that the larger part of the fleshy fungi are included among the Basidiomycetes, and while the Agaricaceæ furnish the greater number of forms of paramount interest to the average layman, nearly all families of these fungi contribute showy or edible species—and some families numerous species. In the Polyporaceæ and Boletaceæ the spore-bearing surfaces are in the form of pores. In the genus Polyporus the plants are tougher in texture than those usually edible, and the larger number grow on wood and trees—some causing the more destructive diseases of wood and timber. One of the edible forms frequently observed and most conspicuous is *Polyporus sulphureus*, which forms immense clusters of sulfur-yellow and orange, bracket-like sporophores on a variety of trees and stumps. Many species of Boletus are edible, but some are to be avoided, and



2416. Boletus subtomentosus.



2417. Clavaria aurea.—Coral fungus. Edible. (×½)

some positively toxic. *Boletus edulis* (la cèpe, der Steinpilz) probably furnishes more than any other one species of the fresh wild fungi sold on the markets of European cities. *Boletus subtomentosus* (Fig. 2416) is not poisonous, but is of inferior quality.

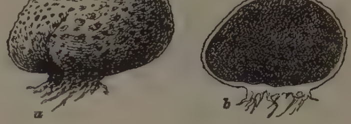
Fistulina hepatica, often known as the beefsteak mushroom, is a juicy, fleshy species with red pileus. The plants are bracketed, and grow from the stumps of several hardwoods. The fungus is prized by many, and while widely distributed it occurs sparingly.

The Hydnaceæ are characterized by a spore-bearing surface spread over teeth or spines arising either from a cap-like pileus or from a tubercular or much-branched structure. Among the edible species *Hydnum repandum* possesses a pileus and true stem. It is of a smoky color and occurs in the autumn on the ground in moist woods. *H. coralloides* (coral hydnum) and *H. erinaceus* (satyr's beard) are both delicate white or creamy fungi—both found in the autumn, on logs or trees.

2418. Lycoperdon craniforme.

In moist wooded places there appear in the late summer and early fall along with Boletus, Russula, and other species, several members of the Clavariaceæ (stag horn or fairy club fungi). In this family the spores are borne over the whole horn or club-like body. These are of various colors from buff to orange or sooty gray. All species which are of sufficient size to be usable are considered edible. *Clavaria aurea* (Fig. 2417), *C. formosa,* and *C. botrytes* are among the larger forms. In the Thelephoraceæ, which include species more or less leathery in texture, the spores are on the lower or outer surface, where that may be distinguished. The horn of plenty, *Craterellus cornucopioides,* a smoky-blue horn-shaped species, is practically the only edible species of interest in this family. The gelatinous fungi, including the Tremellaceæ and allied families, are not of sufficient interest to require special description.

Among the Basidiomycetes in which the spores are differentiated internally, or remain long covered, the puff-balls (Lycoperdaceæ) furnish a number of species of economic importance. All of these plants with white flesh are edible, and some are valuable food accessories. They should be eaten only so long as the flesh is white, and when discolored with age—normally due to the formation of the spores—they must be discarded. The largest species, *Lycoperdon giganteum* (giant puff-ball), frequently attains a diameter of 16 inches, while specimens over 2 feet in diameter have been reported. This species occurs in gardens and meadows. The flesh is pure white until practically full size is attained. *Lycoperdon cyathiforme,* the beaker-shaped puff-ball, is common in pastures in the fall. In the young stages the plants vary in color from creamy white to pink-brown, with white flesh. With the formation of spores it becomes purplish throughout, and leaves a purple beaker-shaped sterile basal part. This is perhaps the puff-ball of highest flavor, and consequently the one which should be known by all persons interested in edible mushrooms. *Lycoperdon craniforme* (Fig. 2418) is found in meadows or in open woods. At maturity the plant shrinks, and may become considerably furrowed, from which character the specific name is derived. Resembling smaller members of the Lycoperdaceæ externally is a fungus, *Scleroderma vulgare* (Fig. 2419), which is black within, tough and inedible.



2419. *a,* **Scleroderma vulgare;** *b,* **section of same.** (×½)

Ascomycetes.

While the larger part of the flesh fungi belong to the Basidiomycetes, nevertheless the few families of the Ascomycetes furnish some forms of special interest. The family Helvellaceæ includes the genus Morchella (morels), as well as Helvella (saddle fungi) and Gyromitra (contorted saddle fungi). There are several species of morels often appropriately called sponge mushrooms, the latter designation being given both on account of the color of the plant and the porous character of the pileus. The morels are widely distributed in the United States. All appear after the warm rains of the spring. They constitute, therefore, about the earliest edible mushrooms. The season is often limited to one or two weeks of favorable weather. *Morchella esculenta* (Fig. 2420) is a common species, and one which appears to be *M. crassipes* is frequently found in the Central States at least. The tuber family (Tuberaceæ) includes all truffles, very aromatic subterranean fungi found for the most part in southern Europe, and there constituting a considerable article of commerce. The mycelium of these plants is associated with the roots of certain trees and shrubs, especially oaks. The species most highly prized are *Tuber melanosporum,* the typical French or black truffle, sometimes called the Périgord truffle, which is commercially much more important than all other species combined; *T. æstivum,* which is the summer truffle of France; and *T. magnatum,* a large smooth species with onion-like flavor, which is the commoner form in Italy. The terfas, or false truffles (Terfeziaceæ), are also subterranean fungi found associated with the roots of certain species of Cistaceæ and Compositæ. The regions of their occurrence are primarily semi-arid sections of northern Africa and localities in the Asiatic Mediterranean country. They are apparently the truffles of ancient times. The plants are spherical or ovoidal in form, and at maturity they have a general resemblance in size and texture to a potato.

B. M. Duggar.

MUSÌNEON (a name for fennel, another plant of this family). Spelled also *Musìneum* and *Musènium*. *Umbelliferæ*. Four species of resinous perennial herbs in Cent. and W. N. Amer., stemless or branching, decumbent or ascending, 2–12 in. high. Lvs. pinnately decompound: fls. yellow or white, in compound naked umbels: fr. ovate or ovate-oblong, somewhat compressed laterally; ribs 5, filiform, slightly prominent, with 2 or 3 oil-tubes in the intervals.

Hoòkeri, Nutt. (*M. trachyspérmum*, Nutt.). Decumbent or ascending, scabrous: lvs., except the radical, opposite, bipinnatifid: fls. yellow: fr. scabrous. Spring. Colo., north.—Procurable from dealers in western native plants.

MUSK. The common musk plant of the gardens is *Mimulus moschatus*, an American plant. The wild musk plant of Europe, however, is *Erodium moschatum.*

MUSK HYACINTH, or GRAPE HYACINTH: *Muscari moschatum.*

MUSK MALLOW: *Hibiscus Abelmoschus* and *Malva moschata.* The musk seed of commerce is *Hibiscus Abelmoschus.*

MUSKMELON: *Melon.*

MUSSÆNDA (a native name in Ceylon). *Rubiàceæ.* Warmhouse or greenhouse plants grown for the flowers and the colored floral bracts or calyx-leaves.

Erect or climbing shrubs or undershrubs, sometimes herbs: lvs. opposite or in 3's, with stipules between, sessile or petiolate: fls. in terminal cymes, yellow, scarlet or white, the corolla tubular and usually funnel-shaped above and the lobes 5; calyx with an oblong or turbinate tube, one of the 5 lobes usually enlarged (in the cult. species) into a white or colored petioled lf. which may make the plant worth cult.; stamens 5, on the corolla-throat or -tube; ovary 2-celled, the style filiform and the stigmas 2: fr. a fleshy many-seeded berry, with an areole at top.—Species probably 40, in the tropics of Afr., Asia and Polynesia. The few species that are sometimes grown are of easy cult.; prop. in spring by cuttings.

A. *Enlarged calyx-lobe or sepal white.*

frondòsa, Linn. Variable species: low erect shrubs, hirsute or glabrate: lvs. either petioled or sessile, oblong to ovate, acuminate; stipules variable, often 2-parted: fls. yellow, the corolla pubescent or hirsute; calyx with an orbicular or elliptic white leafy lobe: berry obovoid, glabrous, with broad areole. India. B.M. 2099 (as *M. pubescens*).

Sanderiàna, Ridley. Compact in habit, 5–6 ft., sometimes prostrate: lvs. close-set, nearly sessile, lanceolate, cordate, silky hairy: fls. yellow, small and tubular, in numerous terminal cymes; petaloid calyx-lobe white, more than 3 in. long, silky-hairy, very showy. Indo-China. G.C. III. 52:228.

AA. *Enlarged calyx-lobe or sepal red.*

erythrophýlla, Schum. & Thonn. Climber or trailer (or apparently sometimes erect), 30–40 ft., the shoots pubescent: lvs. ovate, acuminate, about 6 in. long, with about 10 lateral veins either side the midrib: fls. to 1½ in. long, in dense pedunculate cymes; calyx-tube very short, the lobes red and hirsute and one of them usually produced into a bright vermilion roundish lf. 2–4 in. long; corolla-tube cylindrical, red-hairy, the rounded apiculate lobes white or yellowish inside: fr. nearly or quite 1 in. long, egg-shaped, red-hairy. Trop. Afr. B.M. 8222. G.C. III. 50:91. Gn.W. 4:553.

M. lutèola, Delile. Slender erect twiggy shrub, pubescent: lvs. to 2 in. long, ovate-lanceolate to oblong-lanceolate, acuminate, thin, entire: fls. in 3's in few-fld. cymes, long-tubed, yellow; leafy calyx-lobe white or yellowish, ¾in. or less long, oblong or ovate-cordate. Trop. Afr. B.M. 5573.—*M. Treùtleri*, Stapf. Shrub, somewhat pubescent: lvs. ovate to ovate-elliptic, short-acuminate, to 12 in. long, entire: fls. orange, in many-fld. dense terminal clusters; leafy sepal or calyx-lobe white, shape of the lvs. Trop. Himalaya. B.M. 8254.

L. H. B.

MÚSSCHIA (named after Jean Henri Mussche, of the botanic garden at Ghent). *Campanulàceæ.* Two large robust subshrubs or perennial herbs in Madeira, sometimes grown by amateurs: lvs. radical and cauline, the former large and dentate and the latter few and small: fls. rather large, yellow, or fulvous, in pyramidal panicles; calyx-lobes 5, somewhat foliaceous, colored like the corolla or purple; corolla-tube short, cylindrical, with a 5-lobed spreading or recurved limb; stamens 5, free from the corolla; ovary inferior, 5-celled, many-ovuled, the stigma 5-lobed: caps. opening by numerous transverse lateral slits.

M. aùrea, Dum. (Campanula aurea, Linn. f.). Herb, stemless or developing a st. a few inches high, with thick and fleshy roots, smooth and shining: lvs. in radical tufts, elliptic or elliptic-oblong or lanceolate, serrate: corolla yellow; calyx deeper yellow. B.R. 57.—*M. Wóllastonii*, Lowe. Shrubby, pubescent, the st. simple or somewhat branched: lvs. obovate-oblong, thin and flaccid, sharply serrate: fls. dull dark brownish green or purple. B.M. 5606. G.W. 2, pp. 362, 363.

L. H. B.

MUSTARD, species of Brassica (which see), chiefly *B. alba*, *B. nigra*, *B. juncea* and *B. japonica*. There are two types of mustard-growing,—for the leaves, which are used as a vegetable; for the seeds, which yield oil and are used as a condiment. Table mustard (the flour) is the product mostly of *B. nigra* (Fig. 636, Vol. I), although seeds of *B. alba* and *B. juncea* are also used for making it. The mustards often become prolific weeds, particularly in grain-fields; they are now controlled by herbicides (see *Weeds*). In California, *B. nigra* covers thousands of acres, thriving best on heavy adobe soils. When the winter rains come, it grows lustily, reaching 16 feet high and more. The bulk of the mustard sold in the United States comes from the county of Santa Barbara, Lompoc being the center of the supply.

As a culinary vegetable, mustard is used for "greens" (which see). For this purpose, the large soft basal leaves are desired. These leaves grow best in early spring, although they do fairly well in autumn. If sown late in the season, the plant makes few bottom leaves and runs quickly to seed. Perhaps the best of the mustards for greens in this country is *B. japonica* (Fig. 634, Vol. I), a species which has long been grown in this country, but which has no other well-known name than "mustard." This often seeds itself and comes up the following spring. Some of the large-leaved forms of Chinese mustard (*B. juncea*, Fig. 635) are excellent, and should be better known. One of the oriental species (*B. napiformis*) makes an edible turnip-like root (Fig. 632, Vol. I). Mustard needs a rich quick soil for the producing of the best foliage. Sow the seeds in drills 1 foot or more apart, and thin to 6 inches in the row.

L. H. B.

MUTÍSIA (named after Jos. C. Mutis, 1732–1808 or 1809, botanist of South America). *Compósitæ.* Showy-flowered shrubs, those in cultivation being tendril-climbers; greenhouse or planted out.

Erect or scandent, in cult. likely to be herbaceous, glabrous or tomentose: lvs. alternate, simple or pinnate, the midrib usually produced into a tendril: heads large, heterogamous, usually long and the involucre cylindrical or campanulate, solitary on the ends of branches, the few rays purple, rose-colored or yellow; ray-florets in one series, pistillate; disk-florets hermaphrodite, fertile or sterile; receptacle naked, nearly flat: achene angular, turbinate or oblong, crowned with rigid plumose pappus bristles in one series.—Species about 60, in S. Amer., tropical and extra-tropical. The mutisias have never been popular, although long known to cult. They are plants of attractive habit and showy heads. Some of the species need warmhouse treatment, but the following require cooler treatment, and are probably adaptable to growing permanently out-of-doors in the southern limits of the country. Prop. by cuttings.

A. *Lvs. pinnate.*

Clématis, Linn. f. Climbing herb, rather woody, woolly-pubescent: lvs. pinnate, the rachis extended into a tendril; lfts. 4–5 pairs, short-stalked, oblong-lanceolate, mucronate, entire: heads long-pendulous, oblong-cylindrical, nearly 3 in. long and more than 2 in. across the rays, the latter 9–10, bright red, recurved. Trop. Andes. B.M. 8391. G.C. III. 45:415; 54: suppl. Nov. 29 (colored).—A very vigorous grower, making a good cool greenhouse climber.

AA. *Lvs. simple.*

ilicifòlia, Cav. Climbing slender shrub glabrous or cobwebby: lvs. 1–2 in. long, sessile, cordate or auricled at base, oblong, spiny-toothed and stiff, bright green above, the apex of the blade truncate or 2-lobed, the tendril stout: heads peduncled and solitary in the axils, 3 in. diam., the 8–12 rays pale pink or purplish (pale mauve as described by some). Chile. B.M. 6009. G.C. III. 50:449; 54:383.—The ilex-like foliage is interesting.

decúrrens, Cav. Climbing, the sts. somewhat branched, glabrous: lvs. remote, oblong-lanceolate and entire, acuminate, dark green above and glaucous beneath, tendril bifid, the base of the blade decurrent: head solitary, 4½ in. across, the rays brilliant orange. Chile. B.M. 5273. F.S. 23:2408. G.C. III. 50:451, 452. Gn.W. 24:784.—Perhaps the best species. L. H. B.

MYALL: *Acacia.*

MYÓPORUM (Greek words referring to the translucent resinous dots in the leaves). *Myoporàceæ.* Coolhouse shrubs, more or less heath-like, grown for the small white or purplish flowers; some are trees.

Erect and tall, or diffuse, glabrous or glutinous: lvs. alternate, rarely opposite, entire or toothed, with pellucid glands: fls. axillary, usually clustered, small or medium-sized, mostly white; calyx 5-cut or 5-parted; corolla somewhat bell-shaped or funnel-shaped, the tube very short or long; lobes usually 5, nearly equal or the anterior perhaps larger; stamens 4, or sometimes 5–6; ovary 2–10-celled: fr. a small more or less succulent drupe.—Species 25–30, Austral., New Zeal., China, Japan, Pacific Isls. The genus is divided by Bentham & Hooker into 5 sections based on the shape of the fls., the number of the corolla-lobes and stamens, and the number of cells in the ovary. Usually the calyx-segms. are small and narrow, but in one section they are leafy. One of the species (known in cult. as *M. parvifolium*) was once a favorite heath-like plant in France. In 1883 it was stated in the Garden that for 20 years many thousand plants of it had been sold annually in the flower-markets of Paris. One grower always had a stock of 30,000 plants. The plants were grown in small pots for room and window decoration in spring. "It is most beautiful as seen with its pale green branches drooping gracefully around the pot sides, and more especially so when the shoots are wreathed with sweet, snow-white blossoms." Prop. by cuttings taken in spring. This species is practically unknown in Amer. Some of them are said to be useful in Calif. for planting near the seacoast. The American gardener may get some general suggestions from the experience recorded under *Epacris* and *Erica*.

A. *Tree of some size.*

sandwicénse, Gray. BASTARD SANDALWOOD, from the sandalwood odor of the wood. NAIO. "A very handsome tree which reaches a considerable size" (Rock): lvs. crowded toward the ends of the branches, alternate, elliptic-lanceolate or oblong-lanceolate, acute or acuminate, fleshy when growing at the seacoast or low elevations, to 6 in. long, entire or serrate, the young ones viscous: fls. white or deep pink, in clusters of 5–8: drupe dry or somewhat fleshy, globose or ovate, white. Hawaiian Isls.; offered in S. Calif.—"Its thick bark is of a dark gray color and deeply irregularly corrugated." Sold as a substitute for sandalwood.

AA. *Shrubs, or the second one sometimes a small tree.*

B. *Lvs. linear or nearly so.*

parvifòlium, R. Br. (*M. álbum,* and *M. rosmarinifòlium,* Hort.). Procumbent shrub: sts. 2 ft. long or more: lvs. ¾–1 in. long, linear or linear-spatulate, thick, sparingly dentate toward the apex: fls. with rather acute lobes which are woolly within. Austral. B.M. 1693. L.B.C. 9:837. Gn. 24, p. 361. R.B. 25:253. G.W. 12, p. 150. V. 7:20.—Not advertised in Amer.

BB. *Lvs. lanceolate to obovate or elliptic.*

lætum, Forst. f. (*M. perforàtum,* Hort.). Shrub or small tree: lvs. 2–4 in. long, lanceolate or obovate-lanceolate, acute or acuminate, finely serrate above the middle, bright green, shining, almost fleshy: fls. small, 2–6 in a fascicle, white spotted purple, 4–9 lines wide, with rounded lobes, which are hairy inside. New Zeal.

acuminàtum, R. Br. Erect glabrous shrub, very variable: lvs. alternate, from elliptic-oblong to lanceolate or linear, somewhat acuminate, to 3 in. long, entire or very few-toothed: fls. in clusters of 2–4 or somewhat more, or solitary, white, the corolla almost campanulate and about ⅓in. long, bearded within, the lobes shorter than the tube: drupe ¼in. or less in diam., almost globular. Austral.; cult. in Calif.

serràtum, R. Br. Erect or somewhat diffuse shrub, usually glabrous, exceedingly variable: lvs. elliptic-oblong or lanceolate, obtuse or acute, more or less serrate or entire: fls. usually smaller than in *M. acuminatum,* white and purple, the corolla-lobes usually as long as the tube. Austral.—Offered abroad.

M. píctum and *M. verrucòsum* are mentioned in lists, but their botanical standing is uncertain.

WILHELM MILLER.
L. H. B.†

MYOSOTÍDIUM (Greek, *like* a *myosotis* or forget-me-not). *Boraginàceæ.* GIANT FORGET-ME-NOT. A monotypic genus confined to the Chatham Isls., off New Zealand, a promising blue-flowered herb for mild climates.

Myosotidium differs from Myosotis in its greater size, mostly large radical lvs., and large winged nutlets. **M. nóbile,** Hook. (*Cynoglóssum nóbile,* Hook. f.), is a stout pilose perennial with long thick cylindrical rootstock, succulent, 1–3 ft. high: radical lvs. broadly ovate-cordate or nearly reniform, petioled, thick and fleshy, 6–12 in. long, but becoming much larger under good conditions in cult.; cauline lvs. few, oblong or broad-ovate, sessile: fls. scentless, dark blue in center and lighter toward the edges (a white-fld. form is reported) in dense corymbose cymes which are 3–6 in. across; calyx deeply 5-parted, the lobes broad-oblong and obtuse; corolla rotate, ½in. diam., the tube short and the rounded lobes spreading: fr. to ¾in. diam. Sandy soil near the sea "once very abundant on the coast-line of the Chatham Isls.," according to Cheeseman, "but now fast becoming rare in a wild state." B.M. 5137. Gn. 30:566; 50, p. 150; 71, p. 143; 75, p. 580. G.C. II. 25:681; III. 21:293; 44:7; 54:47. G.M. 31:219; 52:87. J.H. III. 32:327. G. 32:355. R.H. 1908, pp. 370, 371.—In the south of England near the sea the plant thrives well, making fl.-heads 8 in. across, and with foliage as strong as that of rhubarb; it needs to be renewed from seeds. It is reported not to have succeeded at Santa Barbara. L. H. B.

MYOSÒTIS (Greek, signifying *mouse-ear,* from the leaves). *Boragináceæ.* FORGET-ME-NOT. SCORPION GRASS. A large group of low perennial or annual, more or less hairy, branching, diffuse or erect herbs, inhabiting both the North and South Temperate zones, but the cultivated forms coming mainly from Europe.

Leaves alternate, entire: fls. small, in 1-sided, bractless, at first recurved, terminal racemes; calyx small, 5-cleft; corolla salverform, 5-lobed, the throat crested; stamens 5, included; ovary of 4 almost separate lobes, in fr. forming 4 smooth nutlets attached to the receptacle by their bases.—Thirty to 40 species.

The following are all hardy at the North and are grown in America mainly for out-of-door planting. The flowers are normally blue, often purple when young and turning blue with age. White-flowered forms of all the species may occur. Forget-me-nots prefer moist half-shady places, but an open sunny border will do if it is not excessively dry. The perennials are easily propagated by division or cuttings. Forget-me-nots of gardens (mostly *M. sylvatica* and *M. alpestris*) are spring-flowering, making a good combination with hyacinths, tulips and pansies, although they make attractive masses by themselves. Seeds may be sown from spring to August for the next season's bloom; the plants should have protection in winter. Early-started plants may be used for forcing in a cool greenhouse. Renew the outdoor plants often.

A. *Hairs of the calyx all straight, appressed: perennials.*

B. *St. and lvs. densely setose-hispid with reflexed hairs.*

azòrica, H. C. Wats. Decumbent at the base and diffusely branched, 1 ft. high, densely setose-hispid, with reflexed hairs: lvs. oblong, obtuse or retuse, appressed hairy above, hirsute with reflexed hairs below: racemes sub-secund, dense; calyx almost 5-parted; teeth linear, spreading, clothed with erect, appressed hairs; pedicel about equaling the calyx; corolla larger than in *P. laxa,* 3–3½ lines broad, deeper indigo-blue; throat with a whitish eye. Azores. B.M. 4122. V. 6:75. J.F. 4:340.—Suitable for planting in damp, shady soil. Var. **cœléstina,** Hort., is a form with light blue fls.

BB. *St. and lvs. strigose pubescent or glabrous.*

C. *Infl. not leafy: st. angled.*

D. *Calyx toothed above: fls. large.*

scorpioìdes, Linn. (*M. palústris,* Lam.). TRUE FORGET-ME-NOT of Europe. Sts. from slender, stolon-like rootstocks, slender, decumbent, and rooting below, appressed pubescent or nearly glabrous, 6–18 in. long: lvs. oblong-lanceolate or oblanceolate, nearly sessile: raceme loosely-fld.; pedicels in fr. much longer than the calyx, spreading; lobes of the calyx deltoid, acutish; corolla bright blue, with a yellow eye, limb flat, 3–4 lines broad: nutlets angled and keeled on the inner side. May, June. Eu., Asia. G.C. III. 22:307. Gn. 52, p. 461. G.Z. 6:144 (var. *Goeppingeri*). G. 35:489.—Requires damp, shady ground. Escaped from cult. in the eastern states. Var. **semperflòrens,** Hort., is a dwarf form, 8 in. high, flowering all summer.

DD. *Calyx lobed to the middle or below: fls. small.*

láxa, Lehm. Similar to the preceding species, and also rooting at the lower nodes, pubescence all appressed and scanty or wanting: racemes even more loosely-fld.; calyx-lobes much longer, ovate-lanceolate, acute; corolla-limb smaller and concave, about 2 lines broad, paler blue; throat yellow: nutlets equally convex both sides. May, June. N. Eu., Asia, Amer.—Grows best in muddy places.

2421. Myosotis sylvatica. (×½)

CC. *Infl. leafy toward the base: st. terete.*

cespitòsa, Schultz (*M. Rehsteìneri,* Wartm.). Plant appressed-hairy: st. erect, terete or with short decurrent lines below lvs.: rootstocks short and clustered: lvs. linear-oblong: raceme obtuse, leafy-bracted among lower fls.; pedicels longer than 5-cleft calyx; corolla small, 2 lines diam. Swamps and inundated places. Summer. Eu.—Very similar to *M. laxa* but said to have more terete st., more pubescence and longer pedicels.

AA. *Hairs of the calyx, or at least some of them, hooked and spreading: annuals, biennials or perennials.*

B. *Corolla small, about 1 line broad; limb concave; calyx-hairs nearly all hooked.*

arvénsis, Lam. Annual or biennial, erect, branched, 7–20 in. high, hirsute-pubescent: lvs. oblong or oblanceolate, sessile, obtuse or acutish: raceme loosely-fld.; pedicels in fr. much longer than the calyx; calyx deeply 5-parted; lobes equal, linear, acutish; corolla blue or white, 1–1½ lines broad: nutlet convex outside, keeled inside. June–Aug. Eu., Asia.—Will grow well in dry ground.

BB. *Corolla larger, 3–4 lines broad; limb flat: calyx with only the lower hairs hooked.*

C. *Nutlets sessile: plant hirsute and often cinereous.*

D. *Pedicels 1½–2 times length of calyx: plant 1–2 ft. high.*

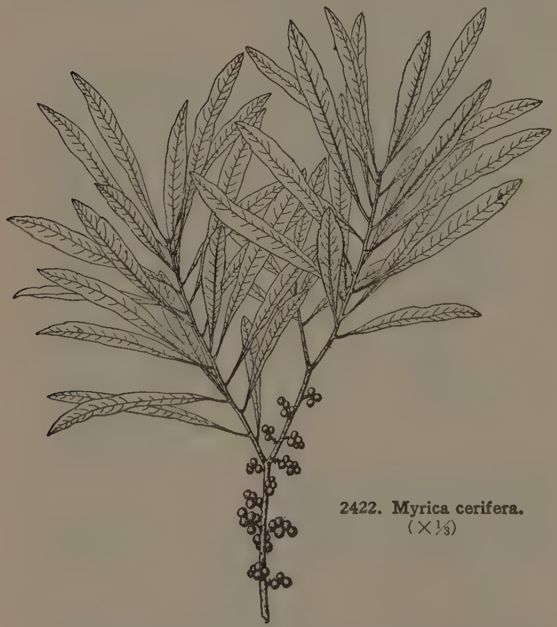
sylvática, Hoffm. Fig. 2421. Perennial, hirsute-pubescent, green or cinereous, erect, 1–2 ft. high, branched above: lvs. oblong-linear or oblanceolate, nearly sessile, acutish: pedicels usually much exceeding the calyx; calyx deeply cleft, hirsute, the hairs, except a few at the base, erect and straight: racemes long and loose; corolla blue, 3–4 lines broad, with a yellow eye: nutlets more or less margined and carinate ventrally, sessile. Spring. Dry soil, Eu., N. Asia. G. 28:520.—Common in cult.

DD. *Pedicels about equaling the calyx, thicker, ascending: plant 3–8 in. high.*

alpéstris, Schmidt (*M. rupícola,* Smith). Similar to the last but dwarf, 3–8 in. high: raceme more dense with shorter thicker ascending pedicels which slightly exceed the calyx: nutlets larger. Summer. Eu. G.C. III. 17:650. Gn.W. 25:544. S.H. 2; p. 25 (1898, f. 203) (as var *stricta*). Gt. 1896, p. 609 (as var. *stricta*). G.W. 2:550 (as var. *stricta*). Gn. 33, p. 93.—Fls. said to be fragrant in the evening. Var. **stricta,** Hort. All the branches erect and strict: appearance peculiar. Var. **aùrea,** Hort. Foliage golden yellow. Commonly cult.

CC. *Nutlets stipitate: plant appressed pubescent.*

dissitiflòra, Baker. Biennial: very similar in habit to *M. sylvatica,* but lower, 6–8 in. high, whole plant clothed with erect-spreading or appressed short hairs: lvs. large, spatulate-oblong, acute, bright green: fruiting racemes more elongated; pedicels ascending or incurved, 2–3 times longer than the calyx; hooked hairs almost absent; calyx-segms. lanceolate, much longer than the tube; corolla 4–5 lines diam. The most important difference is in the nutlets, which are distinctly stipitate. Spring. Switzerland. R.H. 1896, p. 278. S.H. 2, p. 409 (1898, fig. 385). Var. **elegantíssima,** Hort. Lvs. white-edged. The name *M. elegantissima* has also been applied to forms of *M. palustris* and *M. sylvatica.*



2422. Myrica cerifera. (×⅓)

M. Victòria is a fasciated form with hollow st., much crowded, branched, condensed and malformed infl. and irregular enlarged corolla. It is said to come true to seed. Probably derived from M. alpestris. See G.C. III. 10:159; 17:650 (1895).—*M. Wélwitschii,* Boiss. & Reut. A Spanish species with large blue fls.

K. M. WIEGAND.

MYRCIÀRIA (name probably related to Myrtus). *Myrtàceæ.* Brazilian trees and shrubs, of which several species are cultivated for their fruits; sometimes united with Eugenia.

Leaves opposite, entire: fls. sessile or nearly so, axillary, clustered, rarely solitary or in panicles; calyx 4-lobed; petals 4, perigynous, inserted opposite the sepals, deciduous; stamens many; filaments free, filiform; anthers oval or oblong, dehiscing longitudinally; style filiform; stigma simple, rarely capitate; ovary inferior, bilocular, with 2 ovules in each locule; disk small, rarely crowned by the persistent sepals: fr. a berry; seeds 1–4, embryo exalbuminous.—Probably 50 and more species. See *Jaboticaba,* p. 1713.

cauliflòra, Berg. JABOTICABA. The best-known species, considered by Barbosa Rodrigues the handsomest of all the Myrtaceæ. Tree, up to 35 ft.: lvs. elliptical-lanceolate, acute at base and apex: calyx-lobes lanceolate, ciliate: fls. shortly pedicellate, produced directly from the bark of the trunk and branches: fr. ½–1½ in. diam., globose, purplish violet in color, exocarp astringent. Mountains of Rio de Janeiro and Minas Geraes. Pacific Garden, June 1915, p. 12.

jaboticàba, Berg. JABOTICABA DE SÃO PAULO. JABOTICABA DE CABINHO. Tree, 20–30 ft.: lvs. lanceolate or ovate-lanceolate, acute, the base obtuse: calyx-lobes acute, ciliate: fls. shortly pedicellate, produced directly from the bark of the trunk and branches: fr. similar to that of *M. cauliflora* in general appearance; depressed-globose, almost black, ½–1 in. diam., peduncle usually longer than in *M. cauliflora.* Forests of São Paulo and Rio de Janeiro.

F. W. POPENOE.

MYRÌCA (ancient Greek name, possibly applied originally to the tamarisk). *Myricàceæ.* WAX MYRTLE. Ornamental woody plants grown chiefly for their handsome foliage and attractive fruits and some species for their edible fruits.

Leaves alternate, short-petioled, without stipules, entire or serrate, resinous-punctate: fls. diœcious or monœcious, without perianth, in unisexual catkins; stamens 2–16, usually 4–6; ovary 1-celled, with 2 slender filiform stigmas: fr. a drupe, dry or succulent, usually coated with a waxy exudation; nut thick-walled, 1-seeded.—About 50 species in the temperate and warmer regions of both hemispheres.

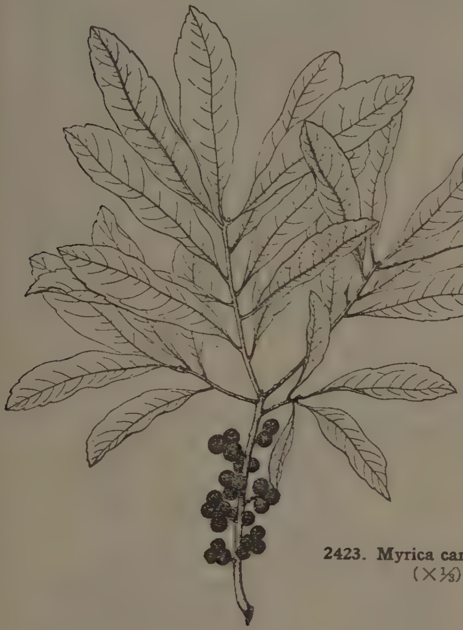
The wax myrtles are aromatic shrubs or small trees with deciduous or evergreen generally oblong leaves and inconspicuous flowers followed by ornamental grayish white or red fruits. Wax is obtained from the fruits of several species; some are cultivated for their succulent and edible fruits. The bark is astringent and used medicinally and in tanning. *Myrica Gale* and *M. carolinensis* are hardy North; *M. cerifera* is somewhat tenderer and *M. californica* is still more tender, while *M. rubra* and *M. Faya* can be grown in subtropical regions only. *M. Gale* and also *M. cerifera* prefer moist and peaty soil, while *M. carolinensis* and *M. californica* grow well in sandy and sterile soil and are widely distributed along the Atlantic and Pacific coasts respectively. Propagation is by seeds sown after maturity; also by layers, and some species, particularly *M. Gale,* by suckers.

A. *Lvs. persistent, or deciduous: fr. globular or ovoid, often coated with wax: fls. with or after the lvs. (Morella.)*

B. *Color of fr. grayish white: fr. dry, densely covered with wax: lvs. often deciduous: stamens 2–6.*

cerífera, Linn. (*Morélla cerífera,* Small. *Cerothámnus cerífera,* Small). Fig. 2422. Slender tree, occasionally to 40 ft., nearly glabrous: lvs. persistent, oblong or oblanceolate, usually acute, cuneate at the base, coarsely serrate above the middle, or entire, dark green above, paler and sometimes pubescent beneath, golden resinous, 1–3 in. long, about ½in. broad: staminate aments cylindric, pistillate aments short: fr. ⅛in. across. March, April. Md. to Fla., Texas and Ark. S.S. 9:459. G.F. 7:476 (adapted in Fig. 2422).—The plant cult. as *M. cerifera* is usually the following species.

carolinénsis, Mill. (*M. pensylvánica,* Lois.). *Morélla carolinénsis,* Small). Bayberry. Fig. 2423. Shrub, 2–8 ft. high: branchlets often pubescent: lvs. subpersistent or deciduous, oblanceolate to obovate, usually obtuse or sometimes acute, cuneate at the base, entire or with a few shallow teeth above the middle, dark green and dull above, sometimes pubescent beneath, resinous, 2–4 in. long and ½–1½ in. broad: fr. ⅙in. across. March, April; fr. in Sept., Oct. Nova Scotia to Fla. and Ala., also on the shores of Lake Erie. G.F. 7:477 (adapted in Fig. 2423). F.E. 23:825 (as *M. cerifera*).—Handsome shrub, hardier than the preceding, with which it is often confused; conspicuous in winter when covered with its grayish white frs. which stay on the branches until spring.



2423. Myrica carolinensis. (×⅓)

bb. *Color of fr. red: lvs. evergreen.*

c. *Frs. distinct in small clusters on short scaly stalks: staminate fls. in simple catkins.*

califórnica, Cham. Slender tree, occasionally to 40 ft.: branchlets pubescent: lvs. lanceolate or oblong-lanceolate, acute, cuneate, remotely serrate, dark green and lustrous above, glabrous or puberulous beneath and marked with minute black dots, 2–4 in. long and ½–¾ in. broad; stamens 5–8: fr. globose, about ¼in. across, papillose, thinly coated with wax. May, June; fr. in Sept., falling during the winter. Wash. to Calif. S.S. 9:461. J.H.S. 1852:283.—One of the prettiest Californian native shrubs, but not easily transplanted and difficult to prop.

rùbra, Sieb. & Zucc. (*M. Nàgi,* DC., not Thunb.). Shrub or small tree: branchlets slightly pubescent: lvs. oblong-lanceolate, acutish, cuneate, entire or serrate above the middle, dark green above, paler beneath, glabrous, 3–5 in. long: staminate catkins cylindric; stamens 6–10: fr. globose or ovoid, tuberculate, deep red-purple, ½–1 in. across; stone ovoid, compressed. April, May; fr. in July. S. China, Japan. B.M. 5727. S.I.F. 2:6.—Cult. for its edible fr. There is a variety with rose-colored finer flavored fr. The berries are vinous and sweet with a pleasant acid taste and are used like blackberries; the fresh juice makes an agreeable beverage. The tree is supposed to stand about 15° of frost. Intro. in 1889. The *M. Nagi,* Thunb., is *Podocarpus Nagi.*

cc. *Frs. 3–4 in small subglobose heads resembling a single 3–4-celled fr.: staminate fls. in panicles.*

Faỳa, Ait. (*Faỳa fragífera,* Webb). Shrub or small tree, to 25 ft.: branches glabrous: lvs. oblong-lanceolate, acute, cuneate, entire or serrate, glabrous, 2–4 in. long: staminate fls. with 4 stamens; pistillate fls. and frs. in elongated spikes: fr. red, edible, ¼in. across. Canary Isls., Madeira, Azores. N.D. 2:56.

aa. *Lvs. deciduous: frs. inclosed by 2 persistent wing-like bracts, forming dense ovoid-oblong, cone-like catkins: fls. before the lvs.* (*Gale.*)

Gàle, Linn. (*Gàle palústris,* Chevalier). Shrub, 1–5 ft.: branches dark brown: lvs. oblanceolate, obtuse, rarely acute, cuneate, serrate toward the apex, dark green and glabrous above, usually pubescent beneath, 1–2½ in. long: staminate catkins about ½in. long, brownish: fr. compressed, 3-pointed, yellowish, golden-resinous, in catkins about ⅓in. long, crowded at the end of last year's branches. April; fr. in Sept. N. Amer., south to Va., Mich. and Wash., Eu., N. Asia. H.W. 2, p. 97. B.B. (ed. 2) 1:584. Var. **subglàbra,** Fern. Lvs. glabrous or nearly so.

M. aspleniifòlia, Linn.=Comptonia aspleniifolia.—*M. sápida,* Wall. Allied to M. rubra. Tree: branches pubescent: lvs. oblong to oblanceolate, 3–6 in. long: staminate fls. in panicles: fr. in elongated spikes, ellipsoid, ⅓in. long; nut pointed at both ends, edible. Himalayas, India, Malay Archipelago. Wallich, Tent. Fl. Nepal. 45.

Alfred Rehder.

MYRICÀRIA (derived from *Myrica,* probably the ancient name for the tamarisk, in allusion to the close affinity of the genus to the tamarisk). *Tamaricàceæ.* A genus of about 10 species distributed from Eu. through Cent. Asia to China; closely related to Tamarix, chiefly distinguished by the 10 stamens being connate one-third to one-half, by the 3 sessile stigmas and the stalked tuft on hairs on the seeds. They are hardy shrubby or suffruticose plants with alternate scale-like lvs. and with the fls. in terminal, often panicled racemes. **M. germánica,** Desv. (*Támarix germánica,* Linn.), is a glabrous undershrub, 4–6 ft. high, with upright, wand-like branches: lvs. minute, bluish green, lanceolate, glandular-dotted: fls. light pink or whitish, in 4–6 in. long, terminal racemes, usually with lateral ones at the base; bracts produced into a narrow lanceolate point, broadly winged below, exceeding the buds; stamens connate about one-half. Cent. and S. Eu., W. Asia. S.O.B. 3:131. G.W.H. 38. **M. dahùrica,** Ehrenb. (*Támarix dahùrica,* Willd.), is very similar, but racemes usually lateral, the bracts oblong-ovate, acute with a membranous margin all around, not exceeding the buds, and stamens connate only one-third. Dahuria, Transbaikalia. The cult. is the same as of tamarix; they prefer sandy, moist soil. Alfred Rehder.

MYRIOCÉPHALUS (Greek, *ten-thousand-headed*). *Compósitæ.* Annual or perennial herbs, all Australian, often hoary, especially when young.

Leaves alternate, entire: clusters or compound heads terminal, usually globose or hemispherical; heads exceedingly numerous and sessile on a broad, very flat receptacle, surrounded by a general involucre of numerous narrow bracts in many rows, each usually with a scarious tip or radiating appendage. In *M. Stuartii* these appendages are 1–2 lines long, broad, white and very conspicuous.—About 8 species.

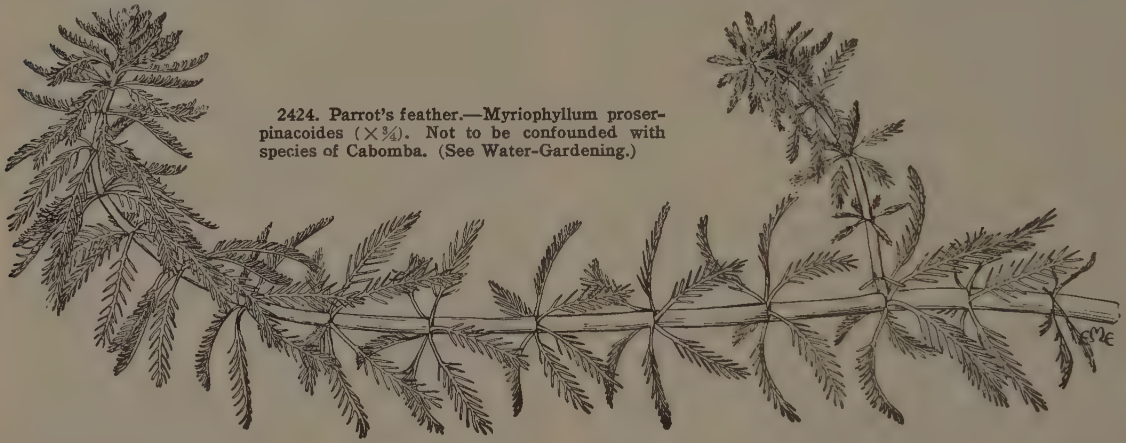
Stùartii, Benth. (*Polycalýmma Stùartii,* F. Muell. & Sond.). Pubescent or woolly, not much branched: lvs. linear or lanceolate, half st.-clasping, 1–2 in. long: clusters hemispherical, 1 in. or more across; partial heads 5–8-fld.: seeds woolly; pappus of numerous ciliate bristles.—Very rare in American collections. An odd sort of everlasting flower, known to the trade as *Polycalymma Stuartii.* It is a half-hardy plant, growing about 1½ ft. high and bearing yellow and white heads.

N. Taylor.†

MYRIOPHÝLLUM (Greek, *myriad-leaved*). *Haloragidàceæ.* Parrot's Feather. Water plants, used in aquaria, fountains and pools.

One of the eight genera of the widespread water-milfoil family, other genera being Gunnera, Hippuris and Proserpinaca, all with minute or inconspicuous individual fls. but interesting and various in foliage. Lvs. whorled or alternate, emersed and immersed, the former entire, dentate or pinnate, the latter divided into capillary segms.: fls. usually monœcious, diœcious or polygamous, in axillary clusters or spikes; calyx none, or present and minutely 2–4-lobed; petals 2–4; stamens 4–8; ovary 2–4-celled, each cell with a solitary ovule.—Species about 20, in fresh water in many parts of the world, from the tropics to the frigid zones. Various native species are likely to be transferred to ponds and aquaria.

The parrot's feather is a favorite aquatic plant, with delicate feathery foliage, composed of numerous whorls of finely cut leaves. The one often seen in vases and fountains in public parks has the uncomfortable name of *Myriophyllum proserpinacoides.* It is a half-hardy plant from Chile, with weak stems which grow out of the water about 6 inches. It may be planted in a water-tight hanging-basket, and if water can be kept standing on the surface, the plant will hang gracefully over the edges. Although detached floating branches will persist for some time, the plant needs earth in which to root. The other species here described are hardy plants, which are common in our eastern ponds. Any one of them may be gathered for the aquarium, and the last two are procurable from dealers in aquatics and aquarium supplies. All of them are readily propagated by long cuttings inserted in the earth or mud of the aquarium or pond. (William Tricker.)



2424. Parrot's feather.—Myriophyllum proserpinacoides (×¾). Not to be confounded with species of Cabomba. (See Water-Gardening.)

A. *Lvs. all alike.*

proserpinacoìdes, Gill. Parrot's Feather. Fig. 2424. Lvs. in whorls of 4–6, 7–12 lines long; segms. 10–25. Chile. G.W. 15, p. 680.—It has escaped from cult. in N. J., but apparently has not persisted. Differs from the 2 following in being diœcious. The female plant is the one in cult.

AA. *Lvs. above the surface of the water different from those below.*

B. *Lvs. whorled in 3's and 4's.*

verticillàtum, Linn. Floral lvs. pectinate or pinnatifid, longer or shorter than the fls.; submerged lvs. in crowded whorls, the divisions very fine or slender: stamens 8; petals deciduous: carpels even. Canada and N. U. S. Eu.

BB. *Lvs. whorled in 4's and 5's.*

heterophýllum, Michx. Floral lvs. ovate, lanceolate, sharply serrate, or even entire, much longer than fls.: stamens 4 or 6; petals rather persistent: carpels 1–2-ridged and roughened on the back. Lakes and rivers. Ont. to Fla. and Minn.

Wilhelm Miller.

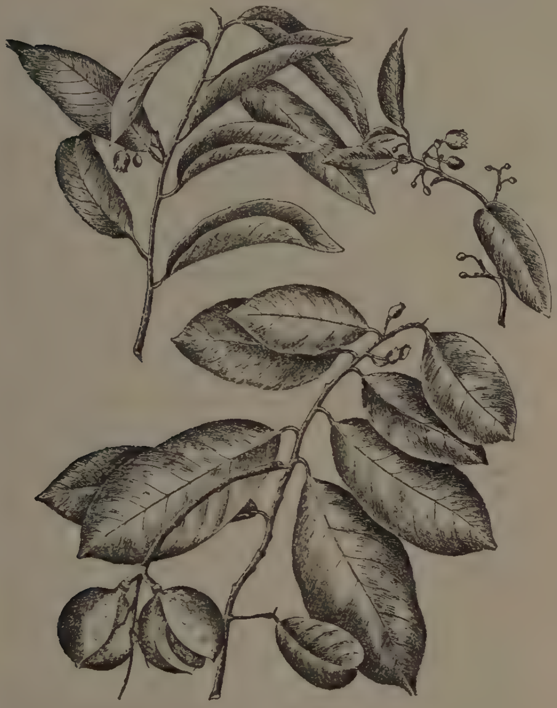
MYRÍSTICA (Greek, alluding to the aromatic qualities of the plants). *Myristicàceæ.* Nutmeg. Myristicas are of many species, but most of the nutmegs of commerce are the product of **M. fràgrans,** Houtt. (*M. moschàta,* Thunb. *M. officinàlis,* Linn. f. *M. aromática,* Lam.), shown in Figs. 2425, 2426. This tree is cult. and naturalized in the W. Indies. The genus Myristica is the only one in the family under the old treatment, but it is now divided by Warburg into 8 genera. As delimited, Myristica comprises about 80 species in farther India, Austral., and Pacific Isls. As formerly defined they are diœcious trees with alternate, entire, pinnate-veined lvs., and small fls. in axillary clusters: perianth 2–4- (usually 3-) lobed, in a single series; anthers 3 or more, connate; ovary single, 1-loculed, ripening into a fleshy fr. The nutmeg of commerce is the seed. This is surrounded by a ruminate aril, which furnishes the mace of commerce. The fr. of *M. fragrans* is short-pear-shaped, to nearly globular, 1½–2 in. long, hanging, reddish or yellowish, somewhat fleshy, splitting at maturity into 2 valves and disclosing the scarlet aril or mace. Inside the aril is the hard nut or shell, and inside the shell is the nutmeg. The details of the mace and nutmeg are shown in Fig. 2426. For a full illustrated and historical account of the nutmeg, see B.M. 2756, 2757 (1827). The nutmeg has not been grown to any extent in the western hemisphere, the commercial supply of nuts and mace coming mostly from the E. Indies.

L. H. B.

The nutmeg tree requires a position in well-sheltered, hot, moist valleys in the tropics from sea-level up to 400 or 500 feet; it will grow and produce fruit in Jamaica up to 2,000 feet, but the fruit is not so abundant nor the nut so large as at lower elevations. The soil must be a deep rich loam, well drained. The seedlings have a tap-root which is very easily injured in transplanting. The method usually adopted for growing them is to sow the seeds in bamboo pots, one in each. When they are ready for planting in their permanent places, the bamboo is slit, and the soil, with the plant, gently put into the prepared hole. It is only when they first flower that it is possible to tell the sex of the tree. Nothing is known of the conditions which determine the sex. In Grenada (British West Indies), the usual proportion of male trees to female is said to be as three to one, though sometimes forty or fifty trees close together will all be either male or female. As the trees generally flower when they are six or seven years old, there is great waste in the growth of male trees. In the Botanic Gardens in Jamaica, it has been found possible to graft the nutmeg, so that a loss of this kind should not occur again; the plan is, take young seedlings and graft, by approach, the thinnest twigs of a female tree.

Wm. Fawcett.



2425. Myristica fragrans—the nutmeg. The upper sprays are from the staminate tree. (×¼)

MYRMECÒDIA (*murmekos*, an ant: the ants nest in excavations that they make in the great tubers). *Rubiàceæ.* From 20–25 remarkable epiphytic sub-shrubs of E. Asia and the Pacific Isls., sometimes grown by the curious. They require the treatment of epiphytic orchids. The plants are glabrous, with 4-angled thickish or fleshy branches: lvs. crowded at the ends of the branches, opposite, obovate; stipules persistent, curiously transformed into scales: fls. small, white, sessile amongst the lvs. and modified stipules. *M. Antòinii,* Becc. (*M. echinàta,* Ant.). Tuber very large, 6 in. or more diam., dull gray, tuberculate and spiny: st. inclined and flexuous, 4-grooved, the ribs covered with imbricating woody shields (stipules): lvs. at top of st., 4 or 5 in. long, elliptic-ovate to obovate, acute: fls. ½in. long, white, sessile on the ribs; corolla clavate, 4-lobed. Torres Straits. B.M. 7517. G.W. 13, p. 117; 14, p. 524.

L. H. B.

MYROBALAN: One of the genus Myrobalanus, now referred to Terminalia (which see). **Myrobalan Plum:** *Prunus cerasifera.*

MYRÓXYLON (*myrrh wood*, from the scent). Syn. *Toluífera. Leguminòsæ.* A few balsam-bearing trees of S. Amer., scarcely cult. horticulturally. Lvs. odd-pinnate; lfts. exstipellate, glandular-punctate: fls. more or less papilionaceous, white or whitish, in axillary simple racemes or paniculate at ends of branches; calyx irregularly dentate; standard orbicular; 4 inferior petals subequal, narrow and free; stamens deciduous with the petals, free or connate at base: pod stalked, compressed, indehiscent, at the apex hardened and 1-seeded, the basal part long and narrow and 2-winged. See also *Toluífera. M. toluíferum,* HBK. (*Toluífera Balsàmum,* Linn.). Tolu-Balsam Tree. Tree, to 75 ft. or more, with thick rough bark and a straight trunk: lfts. 7–11, alternate, oblong and acuminate, quite glabrous, 2–3½ in. long: the balsam is secured from incisions in the bark. *M. peruíferum,* Linn. f. Peru-Balsam Tree (but not the source of Balsam of Peru, which is from *M. Pereiræ,* of San Salvador). Beautiful tree: lfts. 9–13, ovate-oblong, alternate and emarginate at the apex, entire, puberulous on the midrib and petiole, punctate, 1½–3 in. long: fls. in simple racemes 4–5 in. long, long-pedicelled.

L H. B.

MÝRRHIS (from the Greek word for perfume). *Umbellíferæ.* Myrrh. One perennial herb native to Europe and an immigrant to other countries, sometimes grown in gardens for its pleasing scent and anciently used as a flavoring in salads. In America Myrrhis is represented by Osmorhiza (which some writers now call Washingtonia), which is known as sweet cicely. Two or three of the American plants have been named under Myrrhis, but the genus is now excluded from this country. It is closely allied to Chærophyllum. Technical characters distinguish the two genera.

The myrrh of the Arabs is the gum of *Balsamodendron Myrrha,* a burseraceous tree which is now referred to Commiphora; not in cult.

odoràta, Scop. Myrrh. Sweet Cicely of Eu. Soft-hairy or pubescent, erect, branching, 2–3 ft.: lvs. thin and soft, 2–3-pinnate, with narrow-toothed or pinnatifid lanceolate segms.: fls. small, whitish, in a compound umbel which is devoid of a general involucre: fr. ½in. long, longitudinally ribbed. Eu. Gn. 72, p. 18. G.W. 15, p. 131.—Herbage sweet-scented. Rarely seen in this country, but interesting for its graceful foliage; seed may be sown in autumn as soon as ripe, and the plants will come up in spring; prop. also by division; the plant persists for years.

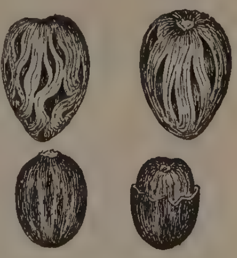
L. H. B.

MYRSÌNE (an old Greek name for the myrtle, of no application; the myrtle is *Myrtus communis*). *Myrsinàceæ.* Shrubs and trees with coriaceous leaves and whitish or yellowish small flowers, of tropical and warm countries.

As formerly constituted and accepted by botanists, a genus of about 80 species: glabrous or tomentose: lvs. leathery, mostly entire: fls. small, sessile or peduncled, in axillary or lateral clusters, polygamo-diœcious; floral parts in 4–5's, the corolla-lobes imbricated in the bud; anthers short and usually blunt: fr. a pea-shaped drupe, dry or fleshy, 1-stoned; seed globose. The family has been re-elaborated by Mez (in Das Pflanzenreich, IV:236 1902), and the genus Myrsine is restricted to 4 species in Asia and Afr. The species here described then become Rapanea and Suttonia.

a. *Fls. with separate petals.* (*Suttonia.*)

Lessertiàna, A. DC. (*Suttònia Lessertiàna,* Mez). Tree, 60 ft., with trunk to 2 ft. diam. with gray bark: lvs. elliptic to obovate, sessile or short-petioled, obtuse and mostly rounded at apex, black-dotted above: fls. yellowish, with reddish dots, in fascicles in the older axils and along the branchlets and on projecting spurs; petals broad-elliptic, twice longer than calyx: drupe globose, reddish or black. Hawaii; intro. in S. Calif.

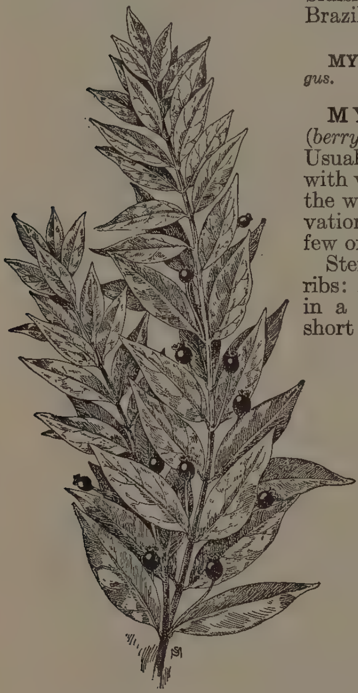


2426. Nutmegs. The upper specimens show the aril or mace. The lower left specimen shows the nut after the mace is removed. The lower right specimen shows part of the shell removed, disclosing the nutmeg. (×⅓)

aa. *Fls. gamopetalous.*

guyanénsis, O. Kuntze (*Rapànea guyanénsis,* Aubl. *Myrsìne Rapànea,* Roem. & Schult. *M. floribúnda,* R. Br. *M. floridàna,* A. DC.). Glabrous shrub or small tree: lvs. 3–4 in. long, mostly at ends of branches, leathery, obovate-oblong, rounded or notched at top, revolute at margin, rusty and dotted beneath, devoid of pellucid dots: fls. sessile or very nearly so; corolla rotate, whitish, much longer than the purple-spotted sepals: drupe small (⅙in. diam.), bluish or black. S. Fla. to Brazil and Paraguay.

L. H. B.



2427. Myrtus communis. (×½)

MYRSIPHÝLLUM: *Asparagus.*

MYRTILLOCÁCTUS (*berry* and *cactus*). *Cactàceæ.* Usually large trees or shrubs with very many branches in the wild state, but in cultivation often small, with few or no branches.

Stems with few angles or ribs: fls. very small, several in a cluster, diurnal, with short tubes and widely spreading petals: fr. a small edible berry.—The genus contains 3 or 4 species.

geométrizans, Console (*Cèreus geométrizans*, Mart.). Plants 10–15 ft. high: ribs 5–9, obtuse, with broad intervals: spines 3–6, the central one much longer and dagger-shaped: fr. the size of an olive, bluish, much eaten by the Mexicans. Common on the tableland of Cent. and S. Mex.

Còchal, Brit. & Rose (*Cèreus Còchal*, Orcutt). Said to grow 10 ft. high: ribs 4–8, obtuse: spines few, the central not so long as in the last: fr. said to be red. Low. Calif.—Not common, and not to be recommended for small collections.

J. N. Rose.

MYRTLE: *Myrtus communis.* **Crape M.**: *Lagerstrœmia.* **Running M.**: *Vinca minor* and others. **Sand M.**: *Leiophyllum.*

MÝRTUS (*Myrtos*, the ancient Greek name). *Myrtàceæ.* Myrtle. Mostly shrubs, grown for the aromatic qualities, attractive foliage, flowers and fruits.

Leaves opposite, entire, penniveined, usually aromatic: fls. white or rose-tinged, axillary, 1 to many, the central on short lateral or long pedicels; calyx-tube turbinate, 5- (rarely 4-) lobed, usually persistent; petals 5 (rarely 4); stamens numerous, in several rows, free; ovule 2–3-celled: fr. a berry, adnate to, or included in the calyx-tube.—A genus of perhaps 70 species, mostly subtropical natives of S. Amer. and Austral., but also in S. Eu. and W. Asia. Some of the myrtles are now referred to Eugenia and other genera. In common speech, the word myrtle is applied to other small-lvd. evergreens as to the vincas or periwinkles.

Myrtles are grown in pots for greenhouse, window or room decorations, or in California and the South as outdoor ornamental shrubs. In pots, they make excellent lawn and terrace plants, being given protection in winter. They are easily cultivated and readily propagated from firm or partially ripened cuttings. They like an abundance of water in summer.
